

**EES 217 Physical and Chemical Hydrology**  
**HW #2**  
**Due: Wednesday Feb 13**

Two multi-level samplers (MW-1 and MW-2), 1 kilometer apart, are installed in a 40 meter thick unconfined sand and gravel aquifer that has a point source of contamination from leaking detergent tanks. The ports

(A,B,C) on the multi-level samplers are spaced at 10 meters apart with the first port (A) positioned at 10 meters below the water table. The results of the analysis are summarized below.

	MW-1	MW-2
Water level (Elevation in meters)	45.000	40.000
Land Surface (Elevation meters)	50.000	50.000
<b><sup>3</sup>H values(TU)</b>		
Port A	20	22
Port B	28	22
Port C	26	24
<b><sup>3</sup>He/<sup>4</sup>He Values ( as R/R<sub>AIR</sub>)</b>		
Port A	1.274	1.310
Port B	2.118	1.794
Port C	3.8	3.7
<b>Detergent Concentration (ppm)</b>		
Port A	10	0.1
Port B	100	20
Port C	5	100
<b>Porosity</b>	0.3	0.3

A) Determine the age of water at each sampling port and plot age versus depth below the water table. Why does the lower sampling port fall off a line drawn between the two upper sampling ports? Determine the vertical groundwater flow velocities from the upper two ports and determine the annual recharge rate from these two ports extrapolated to the water table. Use the equations in the Cape Cod paper to calculate  $V_o$  [Hint: If you rearrange the equation and plot the natural log of the depth (or  $B/B-z$ ) vs. the age, then the slope of the line will be the recharge]. **SHOW ALL WORK.**

B) Using Calculations from the Vogel Model, calculate horizontal flow velocity( $V_x$ ) and horizontal hydraulic conductivity ( $K_x$ ).

C) Calculate the  $V_x$  at the right hand boundary. Use the water balance (recharge in = flux out) to determine  $V_x$ . How does this  $V_x$  compare with the  $V_x$  from the Vogel Model?

### Important constants:

$$[{}^4\text{He}] \text{ in Water} = 45 \mu\text{cc/kg}$$
$${}^3\text{He}(\text{pcc/kg}) \times (10^{-6}) = {}^3\text{He} (\mu\text{cc/kg})$$
$${}^3\text{He}(\text{TU}) = {}^3\text{He} (\text{pcc/kg}) \times 0.402$$

Age (years) =  $(1/\lambda) * \ln ((\text{Daughter}/\text{Parent})+1)$  (Units of Parent and Daughter must be the same (ie, TU))

$$\lambda = 0.0555 \text{ years}^{-1}$$

$$R_{\text{AIR}} = 1.39 \times 10^{-6} \quad R_{\text{SOL}} = 0.985 R_{\text{AIR}} \quad \text{pcc} = 10^{-12} \text{ cc} \quad \mu\text{cc} = 10^{-6} \text{ cc}$$

The Vogel Model:

$$\text{recharge} = V_z * \text{Porosity} \quad V_z = (B/t) * \ln[B/(B-z)] \quad \Delta X_f = \Delta X_1 / [ ( [B - Z_1] * Z_2) / [ ((B - Z_2) * Z_1) - 1 ] ]$$

$$\Delta X_d = \Delta X_f * ((B - Z_1) / (Z_1)) \quad V_x = (V_z * x) / B \quad x = \text{distance from flow divide}$$

### How to Calculate a ${}^3\text{H}/{}^3\text{He}$ age

In order to determine the age for the sample it is necessary to calculate the amount of tritiogenic  ${}^3\text{He}$  (expressed as  ${}^3\text{He}^*$ ) within the sample. The amount of  ${}^3\text{He}$  within a sample can be shown as:

$${}^3\text{He}_{\text{tritiium}} = {}^3\text{He}_{\text{total}} - {}^3\text{He}_{\text{SOL}} = {}^4\text{He}_{\text{MEASURED}} * [ ({}^3\text{He}/{}^4\text{He})_{\text{Total}} - ({}^3\text{He}/{}^4\text{He})_{\text{SOL}} ]$$

This states that the total amount of  ${}^3\text{He}$  within a sample is a result of the amount of  ${}^3\text{He}$  contributed from solubility with air at the water table and the amount  ${}^3\text{He}$  from tritium decay ( ${}^3\text{He}_{\text{tot}} = {}^3\text{He}_{\text{SOL}} + {}^3\text{He}^*_{\text{tritium}}$  or  ${}^3\text{He}^*_{\text{tritium}} = {}^3\text{He}_{\text{tot}} - {}^3\text{He}_{\text{SOL}}$ ). The amount contained of  ${}^3\text{He}$  dissolved in the water will be a function of the solubility at a given temperature. In this exercise, the  ${}^4\text{He}$  is at solubility equilibrium at  $10^\circ\text{C}$  ( $45 \mu\text{cc/kg}$ ) for all samples.

To determine the amount of  ${}^3\text{He}_{\text{SOL}}$  simply multiply the amount of  ${}^4\text{He}$  by the  $R_{\text{sol}}$ , this yields a number for  ${}^3\text{He}_{\text{sol}}$  in units of  $\mu\text{cc/kg}$ .

We use the measured ratio normalized to the air value ( $1.39 \times 10^{-6}$ ) because air serves as the “standard gas”. For the calculation you can use the “normalized ratio” (and then multiply by  $1.39 \times 10^{-6}$  as shown in the calculations) or convert all ratios to the absolute values by multiplying by the air ratio (e.g.  $2.0 R_{\text{AIR}} = 2.78 \times 10^{-6}$ ).
