## Foreword

The study that was initiated by Birkhoff in 1935 was named "general algebra" by Kurosh in his classic text; the subject is also called universal algebra, as in the text by Cohn. The purpose of general algebra is to make explicit common features of the practice of commutative algebra, group theory, linear algebra, Lie algebra, lattice theory, et cetera, in order to illuminate the path for that practice. Less than twenty years after the 1945 debut of the Eilenberg-Mac Lane method of categorical transformations, the obvious possibility of its application to general algebra began to be realized in 1963; that realization continues in the present book.

Excessive iteration of the passage

$$\mathcal{T}' = \text{theory of } \mathcal{T}$$

would be sterile if pursued as idle speculation without attention to that fundamental motion of theory: concentrate the essence of practice, in order to guide practice. Such theory is necessary to clear the way for the advance of teaching and research. General algebra can and should be used in particular algebra (i.e. in algebraic geometry, functional analysis, homological algebra et cetera) much more than it has been. There are several important instruments for such application, including the partial structure theorem in Birkhoff's "Nullstellensatz", the "commutator" construction, and the general framework itself.

Birkhoff's theorem was inspired by theorems of Hilbert and Noether in algebraic geometry (as indeed was the more general model theory of Robinson and Tarski). His big improvement was not only in generality: beyond mere existence of generalized points, he showed they are sufficient to give a monomorphic embedding. Nevertheless, in commutative algebra his result is rarely mentioned (although it is closely related to Gorenstein algebras). The categorical formulation of Birkhoff's theorem ([62] and [90]), like the pre-categorical ones, involves sub-direct irreducibility and Zorn's lemma. Finitely-generated algebras, in particular, are partially dissected by the theorem into (often qualitatively simpler) finitely-generated pieces. For example, when verifying consequences of a system of polynomial equations over a field, it suffices to consider all possible finitedimensional interpretations, where constructions of linear algebra such as trace are available.

Another accomplishment of general algebra is the so-called commutator theory (named for its realization in the particular category of groups); a categorical treatment of this theory can be found in [75] and [53]. In other categories this theory specializes to a construction important in algebraic geometry and number theory, namely the product of ideals [48]. In the geometrical classifying topos for the algebraic category of K-rigs, this construction yields an internal multiplicative semi-lattice of closed sub-varieties.

In the practice of group theory and ring theory the roles of presentations and of the algebras presented have long been distinguished, giving a syntactic approach to calculation in particular algebraic theories. Yet many works in general algebra (and model theory generally) continue anachronistically to confuse a presentation in terms of signatures with the theory itself that is presented, thus ignoring the application of general algebra to specific theories, like that of  $C^{\infty}$ -rings, for which no presentation is feasible.

Apart from the specific accomplishments mentioned above, the most effective illumination of algebraic practice by general algebra, both classical and categorical, has come from the explicit nature of the framework itself. The closure properties of certain algebraic sub-categories, the functorality of semantics itself, the ubiquitous existence of functors adjoint to algebraic functors, the canonical method for extracting algebraic information from non-algebraic categories, have served (together with their many particular ramifications) as a partial guidance to mathematicians in dealing with the inevitably algebraic content of their subjects. The careful treatment of these basics, by Adámek, Rosický, and Vitale, will facilitate future mutual applications of algebra, general algebra, and category theory. They have achieved in this book a new resolution of several issues that should lead to further research.

What is General Algebra?

The bedrock ingredient for all its aspects is the use of finite cartesian products. Therefore, as a framework for the subject, it is appropriate to recognize the 2-category of categories that have finite categorical products and of functors preserving these products. Among such categories there are the linear ones whose products are simultaneously co-products; that is a crucial property of linear algebra in that maps between products are then uniquely represented as matrices of smaller maps between the factors (though of course there is no unique decomposition of objects into products, so it would be incorrect to say inversely that maps "are" matrices). General categories with products can be forced to become linear and this reflection 2-functor is an initial ingredient in linear representation theory. However, I want to emphasize instead a strong analogy between general algebra as a whole and any particular linear monoidal category, because that will reveal some of the features of the finite product framework that make possible the more profound results.

The 2-category of all categories with finite products has (up to equivalence)

#### . FOREWORD

three characteristic features of a linear category such as the category of modules over a rig:

- 1. It is "additive" because if  $A \times B$  is the product of two categories with finite products, it is also their coproduct, the evident injections from A, B having the universal property for maps into any third such category.
- 2. It is "symmetric closed"; indeed Hom(A, B) is the category of algebras in the background *B* according to the theory *A*. The unit *I* for this Hom is the opposite of the category of finite sets. The category *J* of finite sets itself satisfies Hom(J, J) = I, and the category Hom(J, B) is the category of Boolean algebras in *B*. As dualizer, the case B = small sets is most often considered in abstract algebra.
- 3. It is "tensored" because a functor of two variables that is product-preserving in each variable separately can be represented as a product-preserving functor on a suitable tensor-product category. Such functors occur in recent work of Zurab Janelidze [52]; specifically, there is a canonical evaluation  $A \otimes \text{Hom}(A, B) \to B$ , where the domain is "a category whose maps involve both algebraic operations and their homomorphisms".

A feature not present in abstract linear algebra (though it has an analogue in the cohesive linear algebra of functional analysis) is Ross Street's bo-ff factorization of any map (an abbreviation of "bijective on objects followed by full and faithful"), see [88] and [89]. A single-sorted algebraic theory is a map  $I \to A$ that is bijective on objects; such a map induces a single "underlying" functor  $\operatorname{Hom}(A, B) \to B$  on the category of A-algebras in B. The factorization permits the definition of the full "algebraic structure" of any given map  $u: X \to B$  as follows: the map  $I \to \operatorname{Hom}(X, B)$  that represents u has its bo-ff factorization, with its bo part the algebraic theory  $I \to A(u)$ , the full X-natural structure (in its abstract general guise) of all values of u. The original u lifts across the canonical Hom $(A(u), B) \to B$  by a unique  $u^{\#}$ . This is a natural first step in one program for "inverting" u, because if we ask whether an object of B is a value of u, we should perhaps consider the richer (than B) structure that any such object would naturally have; that is, we change the problem to one of inverting  $u^{\#}$ . Jon Beck called this program "descent" with respect to the "doctrine" of general algebra. (A second step is to consider whether  $u^{\#}$  has an adjoint.)

Frequently, the dualizing background B is cartesian-closed, i.e., it has not only products but also finite co-products and exponentiation, where exponentiation is a map

$$B^{op} \otimes B \to B$$

in our 2-category. This permits the construction of the important family of function algebras  $B^{op} \to \text{Hom}(A, B)$  given any A-algebra (of "constants") in B. On a higher level, the question whether a given C is a value of the 2-functor U = Hom(-, B) (for given B), leads to the discovery that such values belong to a much richer doctrine, involving as operations all limits that B has and all co-limits that exist in B and preserve finite products. As in linear algebra, where

dualization in a module B typically leads to modules with a richer system of operators, conversely such a richer structure assumed on C is a first step toward 2-descent back along U.

The power of the doctrine of natural 2-operations on Hom(-, B) is enhanced by fixing B to be the category of small sets, where smallness specifically excludes measurable cardinals (although they may be present in the categorical universe at large).

A contribution of Birkhoff's original work had been the characterization of varieties, that is, of those full subcategories of a given algebraic category  $\operatorname{Hom}(A,B)$  that are equationally defined by a surjective map  $A \to A'$  of theories. Later, the algebraic categories themselves were characterized. Striking refinements of those characterization results, in particular, the clarification of a question left open in the 1968 treatment of categorical general algebra [61], are among the new accomplishments explained in the present book. As Grothendieck had shown in his very successful theory of abelian categories, the exactness properties found in abstract linear algebra continue to be useful for the concretely variable linear algebras arising as sheaves in complex analysis; should something similar be true for non-linear general algebras? More specifically, what are the natural 2-operations and exactness properties shared by all the set-valued categories concretely arising in general algebra? In particular, can that class of categories be characterized by further properties, such as sufficiency of projectives, in terms of these operations? It was clear that small limits and filtered colimits were part of the answer, as with the locally-finitely-presentable categories of Gabriel and Ulmer. But the further insistence of general algebra, on algebraic operations that are total, leads to a further functorial operation, needed to isolate equationally the correct projectives and also useful in dealing with non-Mal'cev categories: that further principle is the ubiquitous preservation of Linton's reflexive co-equalizers, which are explained in this book as a crucial case of Lair's sifted colimits.

Bill Lawvere

Buffalo, October 31, 2009

## Introduction

The concept of an algebraic theory, introduced in 1963 by F. W. Lawvere, was a fundamental step towards a categorical view on general algebra in which varieties of algebras are formalized without details of equational presentations. An algebraic theory, as originally introduced, is roughly speaking a category whose objects all are finite powers of a given object. An algebra is then a set-valued functor preserving finite products and a homomorphism between algebras is a natural transformation. In the almost half of a century that followed, this idea has gone through a number of generalizations, ramifications, and applications in areas such as algebraic geometry, topology, and computer science. The generalization from one-sorted algebras to many-sorted ones (of particular interest in computer science) leads to a simplification: an algebraic theory is now simply a small category with finite products.

#### **Abstract Algebraic Categories**

In the first part of this book, consisting of Chapters 1 - 10, we develop the approach in which algebraic theories are studied without a reference to sorting. Consequently, algebraic categories are investigated as abstract categories. We study limits and colimits of algebras, paying special attention to the sifted colimits since they play a central role in the development. For example, algebraic categories are characterized as precisely the free completions under sifted colimits of small categories with finite coproducts. And algebraic functors are precisely the functors preserving limits and sifted colimits. This leads to an algebraic duality: the 2-category of algebraic categories is dually biequivalent to the 2-category of canonical algebraic theories.

Here we present the concept of equation as a parallel pair of morphisms in the algebraic theory. An algebra satisfies the equation iff it merges the parallel pair. We prove Birkhoff's Variety Theorem: subcategories which can be presented by equations are precisely those closed under products, subalgebras, regular quotients, and directed unions. (The last item can be omitted in case of one-sorted algebras.)

#### **Concrete Algebraic Categories**

Lawvere's original concept of one-sorted theory is studied in Chapters 11 – 13. Here the categories of algebras are concrete categories over *Set*, and we prove that up to concrete equivalence they are precisely the classical equational categories of  $\Sigma$ -algebras for one-sorted signatures  $\Sigma$ . More generally, given a set *S* of sorts, we introduce in Chapter 14 *S*-sorted algebraic theories and the corresponding *S*-sorted algebraic categories which are concrete over *S*-sorted sets. Thus we distinguish between "many-sorted" where sorting is not specified and "*S*-sorted" where a set *S* of sorts is given (and this distinction leads us to considering the categories of algebras as concrete or abstract ones).

This is supplemented by Appendix A in which a short introduction to monads and monadic algebras is presented. There we prove a duality between onesorted algebraic theories and finitary monadic categories over *Set.* And again, more generally, between *S*-sorted algebraic theories and finitary monadic categories over  $Set^S$ .

The non-strict version of some concepts, like morphism of one-sorted theories and concrete functor, is treated in Appendix C.

#### **Special Topics**

Chapters 15 – 18 are devoted to some more specialized topics. Here we introduce Morita equivalence, characterizing pairs of algebraic theories yielding equivalent categories of algebras. We also prove that algebraic categories are free exact categories. Finally, the finitary localizations of algebraic categories are described: they are precisely the exact locally finitely presentable categories. Abelian categories are shortly treated in Appendix B.

. . . .

#### Other Topics

Of the two categorical approaches to general algebra, monads and algebraic theories, only the latter is treated in this book, with the exception of the short appendix on monads. Both of these approaches make it possible to study algebras in a general category; in our book we just restrict ourselves to sets and many-sorted sets. Thus examples such as topological groups are not treated here.

Other topics related to our book are mentioned in the Postscript.

#### **Interdependance of Chapters**

Until Chapter 7 inclusive every chapter is strongly dependent on the previous ones. But some topics in the sequel of the book can be studied by skipping Chapters 2-7 (and consulting them just for specific definitions and results):

algebraic duality in Chapters 8-9

Birkhoff's Variety Theorem in Chapter 10

one-sorted theories in Chapters 11-13

#### . INTRODUCTION

S-sorted theories in Chapter 14 (after reading Chapter 11)

Morita equivalence of theories in Chapter 15

#### Acknowledgments

The authors are indebted to Bill Lawvere who had the idea that a book about algebraic theories was needed, and who followed the years of the development of our project with great interest and with critical comments that helped us immensely. Also discussions with Walter Tholen in the early stages of our book were of great value. We are also grateful to a number of colleagues for their suggestions on the final text, particularly to Michel Hébert, Alexander Kurz, Raul Leal, Stefan Milius, John Power and Ross Street.

Jiří Adámek, Jiří Rosický and Enrico M. Vitale

#### . INTRODUCTION

# Part I: Abstract algebraic categories

"It should be observed first that the whole concept of category is essentially an auxiliary one; our basic concepts are those of a functor and a natural transformation."

S. Eilenberg and S. Mac Lane, *General theory of natural equivalences*, Trans. Amer. Math. Soc. 58 (1945).

. PART I: ABSTRACT ALGEBRAIC CATEGORIES

## Chapter 0

## Preliminaries

The aim of this chapter is to fix some notation and recall well-known facts concerning basic concepts of category theory used throughout the book. The reader may well skip it and return to it where needed. Only the most usual definitions and results of the theory of categories are mentioned here, more about them can be found in any of the books mentioned at the end of this chapter.

**0.1 Foundations.** In category theory one needs to distinguish between *small* collections (sets) and *large* ones (classes). An arbitrary set theory making such a distinction possible is sufficient for our book. The category of (small) sets and functions is denoted by

Set.

All categories we work with have small hom-sets.

#### **0.2 Properties of functors.** A functor $F: \mathcal{A} \to \mathcal{B}$ is

- 1. faithful if for every parallel pair of morphisms  $f, g: A \rightrightarrows A'$  in  $\mathcal{A}$ , one has f = g whenever Ff = Fg,
- 2. full if for every morphism  $b: FA \to FA'$  in  $\mathcal{B}$  there exists a morphism  $a: A \to A'$  in  $\mathcal{A}$  such that Fa = b,
- 3. essentially surjective if for every object B in  $\mathcal{B}$  there exists an object A in  $\mathcal{A}$  with B isomorphic to FA,
- 4. an equivalence if there exists a functor  $F' \colon \mathcal{B} \to \mathcal{A}$  such that both  $F \cdot F'$ and  $F' \cdot F$  are naturally isomorphic to the identity functors. Such a functor F' is called a *quasi-inverse* of F,
- 5. an *isomorphism* if there exists a functor  $F' \colon \mathcal{B} \to \mathcal{A}$  such that both  $F \cdot F'$ and  $F' \cdot F$  are equal to the identity functors,
- 6. conservative if it reflects isomorphisms, that is,  $a: A \to A'$  is an isomorphism whenever  $Fa: FA \to FA'$  is.

#### **0.3 Remark.** Let $F: \mathcal{A} \to \mathcal{B}$ be a functor.

- 1. If F is full and faithful, then it is conservative.
- 2. F is an equivalence iff it is full, faithful, and essentially surjective.
- 3. If F is an equivalence and F' a quasi-inverse of F, it is possible to choose natural isomorphisms  $\eta: \operatorname{Id}_{\mathcal{B}} \to F \cdot F'$  and  $\varepsilon: F' \cdot F \to \operatorname{Id}_{\mathcal{A}}$  such that

$$F\varepsilon \cdot \eta F = F$$
 and  $\varepsilon F' \cdot F'\eta = F'$ 

(compare with 0.8). (Observe that in equations like  $F\varepsilon \cdot \eta F = F$  we write F for the identity natural transformation on a functor F. We adopt the same convention in diagrams having functors as vertices and natural transformations as edges.)

4. F is an isomorphism iff it is full, faithful, and bijective on objects.

#### 0.4 Functor categories and Yoneda embedding.

- 1. Given a category  $\mathcal{A}$  and a small category  $\mathcal{C}$  we denote by  $\mathcal{A}^{\mathcal{C}}$  the category of functors from  $\mathcal{C}$  to  $\mathcal{A}$  and natural transformations, and by  $\mathcal{C}^{op}$  the dual category.
- 2. In case  $\mathcal{A} = Set$  we have the Yoneda embedding

$$Y_{\mathcal{C}}: \mathcal{C}^{op} \to Set^{\mathcal{C}}, \quad Y_{\mathcal{C}}(X) = \mathcal{C}(X, -)$$

which is full and faithful. This follows from the Yoneda Lemma which states that for every  $X \in \mathcal{C}$  and for every functor  $F: \mathcal{C} \to Set$ , the map assigning to every natural transformation  $\alpha: Y_{\mathcal{C}}(X) \to F$  the value  $\alpha_X(\mathrm{id}_X)$  is a bijection natural in X and F.

#### 0.5 Diagrams.

- 1. A *diagram* in a category  $\mathcal{K}$  is a functor from a small category into  $\mathcal{K}$ .
- 2. A finite diagram is a diagram  $D: \mathcal{D} \to \mathcal{K}$  such that  $\mathcal{D}$  is a finitely generated category. This means that  $\mathcal{D}$  has finitely many objects and a finite set of morphisms whose closure under composition gives all the morphisms of  $\mathcal{D}$ .
- 3. A category is *complete* if every diagram in it has a limit; dually: *cocomplete*.
- 4. Limits commute with products: given a set C and a collection of diagrams

$$D_c \colon \mathcal{D} \to \mathcal{A} \ , \ c \in \mathcal{C}$$

in a complete category  $\mathcal{A}$ , then the product of their limits is the same as the limit of their product. This can be formalized by viewing  $\mathcal{C}$  as a discrete category and considering the limit of the obvious diagram  $D: \mathcal{C} \times \mathcal{D} \to \mathcal{A}$ . The statement is that the canonical morphism from limD to  $\Pi(limD_c)$  is an isomorphism.

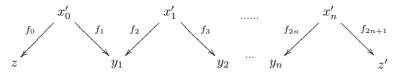

5. Limits commute with limits: this generalizes 4. to the case when C is an arbitrary small category: given a complete category  $\mathcal{A}$  and a diagram  $D: \mathcal{C} \times \mathcal{D} \to \mathcal{A}$ , the canonical morphisms

$$\lim_{C} (\lim_{D} D(c,d)) \cong \lim_{D} (\lim_{C} D(c,d))$$

are mutually inverse isomorphisms. Moreover, each one of these isomorphic objects is a limit of D.

**0.6 Colimits in Set.** In the category of sets:

- 1. Coproducts are disjoint unions.
- 2. Coequalizers of  $p,q: X \implies Z$  can be described as the canonical maps  $c: Z \to Z/\sim$  where  $\sim$  is the smallest equivalence relation with  $p(x) \sim q(x)$  for every  $x \in X$ . This equivalence relation merges elements z and z' of Z iff there exists a zig-zag of elements

where each  $f_k$  is equal to p or to q for  $k = 0, \ldots, 2n + 1$ .

3. A category  $\mathcal{D}$  is called *filtered* if every finitely generated subcategory has a cocone in  $\mathcal{D}$  (for more about this concept see Chapter 2). Filtered diagrams are diagrams with a filtered domain. A colimit of a filtered diagram  $D: \mathcal{D} \to Set$  is described as the quotient

$$\coprod_{x\in \operatorname{obj} \mathcal{D}} Dx/\sim$$

where for elements  $u_i \in Dx_i$  we have  $u_1 \sim u_2$  iff there exist morphisms  $f_i: x_i \to y$  in  $\mathcal{D}$  such that  $Df_1(u_1) = Df_2(u_2)$ .

**0.7 Construction of colimits.** In a category  $\mathcal{A}$  with coproducts and coequalizers all colimits exist. Given a diagram  $D: \mathcal{D} \to \mathcal{A}$  form a parallel pair

$$\coprod_{i \in \operatorname{mor} \mathcal{D}} Df_d \xrightarrow{i}_{j} \prod_{x \in \operatorname{obj} \mathcal{D}} Dx$$

where  $f_d$  and  $f_c$  denote the domain and codomain of f. The f-component of i is the coproduct injection of  $Df_d$ , that of j is the composite of Df and the coproduct injection of  $Df_c$ .

1. If

$$c\colon \coprod_{x\in \operatorname{obj} \mathcal{D}} Dx \longrightarrow C$$

is the coequalizer of i and j, then C = colim D and the components of c form the colimit cocone.

2. The pair i, j above is reflexive, that is, there exists a morphism

$$\delta \colon \coprod_{x \in \operatorname{obj} \mathcal{D}} Dx \longrightarrow \coprod_{f \in \operatorname{mor} \mathcal{D}} Df_d$$

such that  $i \cdot \delta = id = j \cdot \delta$ . Indeed, the *x*-component of  $\delta$  is the coproduct injection of  $id_x$ .

**0.8 Adjoint functors.** Given functors  $U: \mathcal{A} \to \mathcal{B}$  and  $F: \mathcal{B} \to \mathcal{A}$ , then F is a left adjoint of U, notation  $F \dashv U$ , if there exist natural transformations  $\eta: \operatorname{Id}_{\mathcal{B}} \to UF$  and  $\varepsilon: FU \to \operatorname{Id}_{\mathcal{A}}$  (called unit and counit) satisfying

$$\varepsilon F \cdot F\eta = F$$
 and  $U\varepsilon \cdot \eta U = U$ .

This is equivalent to the existence of a bijection

$$\mathcal{A}(FB,A) \simeq \mathcal{B}(B,UA)$$

natural in  $A \in \mathcal{A}$  and  $B \in \mathcal{B}$ .

- 1. Every left adjoint preserves colimits.
- 2. Dually, every right adjoint preserves limits.
- 3. A solution set for a functor  $U: \mathcal{A} \to \mathcal{B}$  and an object X of  $\mathcal{B}$  is a set of morphisms  $f_i: X \to UA_i$   $(i \in I)$  with  $A_i \in \mathcal{A}$  such that every other morphism  $f: X \to UA$  has a factorization  $f = Uh \cdot f_i$  for some  $i \in I$  and some morphism  $h: A_i \to A$  in  $\mathcal{A}$ .
- 4. The Adjoint Functor Theorem states that if  $\mathcal{A}$  has limits, then a functor  $U: \mathcal{A} \to \mathcal{B}$  has a left adjoint iff it
  - (a) preserves limits, and
  - (b) has a solution set for every object X of  $\mathcal{B}$ .

**0.9 Reflective subcategories.** Given a category  $\mathcal{B}$ , by a *reflective subcategory* of  $\mathcal{B}$  is meant a subcategory  $\mathcal{A}$  such that the inclusion functor  $\mathcal{A} \to \mathcal{B}$  has a left adjoint (called a reflector for  $\mathcal{B}$ ). We denote by  $R: \mathcal{B} \to \mathcal{A}$  the reflector and by  $r_B: \mathcal{B} \to R\mathcal{B}$  the reflections, i.e., the components of the unit of the adjunction.

**0.10 Representable functors.** A functor from a category  $\mathcal{A}$  to *Set* is *representable* if it is naturally isomorphic to a hom-functor  $\mathcal{A}(A, -)$ .

- 1. If  $\mathcal{A}$  has coproducts, then  $\mathcal{A}(A, -)$  has a left adjoint assigning to a set X a coproduct of X copies of A.
- 2. The colimit of  $\mathcal{A}(A, -)$  is a singleton set.

3. The Adjoint Functor Theorem can be stated in terms of representable functors as follow:

A functor  $F: \mathcal{B} \to Set$ , with  $\mathcal{B}$  complete, has a left adjoint iff it is representable. This is the case iff it preserves limits and satisfies the solution set condition: there exists a set  $\mathcal{G}$  of objects of  $\mathcal{B}$  such that for any object B of  $\mathcal{B}$  and any element  $b \in FB$ , there are  $X \in \mathcal{G}, x \in FX$  and  $f: X \to B$  such that Ff(x) = b.

#### 0.11 Example.

- 1. For every set X the functor  $X \times :$  Set  $\rightarrow$  Set is left adjoint to Set(X, -).
- 2. For a category  $\mathcal{A}$  the diagonal functor

$$\Delta \colon \mathcal{A} \to \mathcal{A} \times \mathcal{A} \ , \ A \mapsto (A, A)$$

has a left adjoint iff  $\mathcal{A}$  has finite products. Then

$$\mathcal{A} \times \mathcal{A} \to \mathcal{A} , \ (A, B) \mapsto A \times B$$

is a left adjoint to  $\Delta$ .

**0.12 Remark.** The contravariant hom-functors  $\mathcal{B}(-,B): \mathcal{B} \to Set^{op}, B \in obj \mathcal{B}$ , collectively reflect colimits. That is, for every cocone C of a diagram  $D: \mathcal{D} \to \mathcal{B}$  we have: C is a colimit of D iff the image of C under any  $\mathcal{B}(-,B)$  is a colimit of the diagram  $\mathcal{B}(-,B) \cdot D$  in  $Set^{op}$ .

**0.13 Slice categories.** Given functors  $F: \mathcal{A} \to \mathcal{K}$  and  $G: \mathcal{B} \to \mathcal{K}$ , the *slice category*  $(F \downarrow G)$  has as objects all triples (A, f, B) with  $A \in \mathcal{A}, B \in \mathcal{B}$  and  $f: FA \to GB$ , and as morphisms  $(A, f, B) \to (A', f', B')$  all pairs  $a: A \to A'$ ,  $b: B \to B'$  such that  $Gb \cdot f = f' \cdot Fa$ .

- 1. As special cases, we have  $K \downarrow G$  and  $F \downarrow K$  where an object  $K \in \mathcal{K}$  is seen as a functor from the one-morphism category to  $\mathcal{K}$ .
- 2. If F is the identity functor on  $\mathcal{K}$ , we write  $\mathcal{K} \downarrow K$  instead of  $\mathrm{id}_{\mathcal{K}} \downarrow K$ .

**0.14 Set functors as colimits of representables.** Every functor  $A: \mathcal{T} \to Set$  ( $\mathcal{T}$  small) is in a canonical way a colimit of representable functors. In fact, consider the Yoneda embedding  $Y_{\mathcal{T}}: \mathcal{T}^{op} \to Set^{\mathcal{T}}$  and the slice category  $ElA = Y_{\mathcal{T}} \downarrow A$  of "elements of A". Its objects can be represented as pairs (X, x) with  $X \in obj \mathcal{T}$  and  $x \in AX$ , and its morphisms  $f: (X, x) \to (Z, z)$  are morphisms  $f: Z \to X$  of  $\mathcal{T}$  such that Af(z) = x. We denote by  $\Phi_A: ElA \to \mathcal{T}^{op}$  the canonical projection which to every element of the set AX assigns the object X. Then A is a colimit of the diagram of representable functors as follows

$$ElA \xrightarrow{\Phi_A} \mathcal{T}^{op} \xrightarrow{Y_{\mathcal{T}}} Set^{\mathcal{T}}$$

Indeed, the colimit injection  $Y_{\mathcal{T}}(\Phi_A(X, x)) \to A$  is the natural transformation corresponding, by Yoneda Lemma, to the element  $x \in AX$ .

**0.15 Kernel pair.** A *kernel pair* of a morphism  $f: A \to B$  is a parallel pair  $f_1, f_2: N(f) \rightrightarrows A$  forming a pullback of f and f.

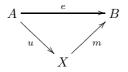

**0.16 Classification of quotient objects.** A quotient object of an object A is represented by an epimorphism  $e: A \to B$ , and an epimorphism  $e': A \to B'$  represents the same quotient iff  $e' = i \cdot e$  holds for some isomorphism  $i: B \to B'$ . We use the same adjective for quotient objects and (any of) the representing epimorphisms  $e: A \to B$ :

- 1. Split means that there exists  $i: B \to A$  with  $e \cdot i = id_B$ . Then B is called a *retract* of A.
- 2. Regular means that e is a coequalizer of a parallel pair with codomain A.
- 3. Strong means that in every commutative square

where m is a monomorphism, there is a "diagonal" morphism  $d: B \to X$ such that  $m \cdot d = v$  and  $d \cdot e = u$ .

4. Extremal means that in every commutative triangle

where m is a monomorphism, then m is an isomorphism.

Dually, a subobject of A is represented by a monomorphism  $m: B \to A$ , and a monomorphism  $m': B' \to A$  represents the same subobject iff  $m' = m \cdot i$  holds for some isomorphism  $i: B' \to B$ .

**0.17 Remark.** Let us recall some elementary facts on extremal, strong and regular epimorphisms.

- 1. Every regular epimorphism is strong and every strong epimorphism is extremal. If the category  $\mathcal{A}$  has finite limits, then extremal = strong.
- 2. If the category  $\mathcal{A}$  has binary products, then the condition of being an epimorphism in the definition of strong epimorphism is redundant. The same holds for extremal epimorphisms if the category  $\mathcal{A}$  has equalizers.
- 3. If a composite  $f \cdot g$  is a strong epimorphism, then f is a strong epimorphism. The same holds for extremal epimorphisms, but in general this fails for regular epimorphisms.

#### CHAPTER 0. PRELIMINARIES

- 4. If f is a monomorphism and an extremal epimorphism, then it is an isomorphism.
- **0.18 Concrete categories.** Let  $\mathcal{K}$  be a category.
  - 1. By a concrete category over  $\mathcal{K}$  is meant a category  $\mathcal{A}$  together with a faithful functor  $U: \mathcal{A} \to \mathcal{K}$ .
  - 2. Given concrete categories  $(\mathcal{A}, U)$  and  $(\mathcal{A}', U')$  over  $\mathcal{K}$ , a concrete functor is a functor  $F \colon \mathcal{A} \to \mathcal{A}'$  such that  $U = U' \cdot F$ .

#### **Further Reading**

For standard concepts of category theory the reader may consult e.g. the following monographs: [4], [28], [54], [68].

CHAPTER 0. PRELIMINARIES

## Chapter 1

## Algebraic theories and algebraic categories

Algebras are classically presented by operations and equations. For example, the theory of groups is presented by three operations:

a binary operation  $\circ$  (multiplication),

a unary operation  $^{-1}$  (inverse),

a nullary operation e (unit)

and by the equations

$$\begin{array}{rcl} x \circ (y \circ z) &=& (x \circ y) \circ z \\ x \circ x^{-1} &=& e \\ e \circ x &=& x \\ x^{-1} \circ x &=& e \\ x \circ e &=& x \end{array}$$

The whole equational theory of groups consists of all consequences of these five equations, for example, it contains the equation

$$x \circ (x^{-1} \circ x) = x$$

The presentation above is not canonical: the first three equations are in fact sufficient, and so is the first one and the last two. There does not seem to exist any canonical "minimal" presentation of groups. But we can consider the equational theory as such. Following the idea of F.W. Lawvere from the 1960s, let us view the three basic group operations as maps

$$\circ \colon G \times G \to G$$
$$^{-1} \colon G \to G$$

$$e \colon G^0 \to G$$

And all derived operations can be obtained via composition. E.g., the operation  $x \circ (y \circ z)$  is the composite

$$G \times (G \times G) \xrightarrow{\operatorname{id}_G \times \circ} G \times G \xrightarrow{\circ} G$$

whereas the operation  $(x \circ y) \circ z$  is the composite

$$(G \times G) \times G) \xrightarrow{\circ \times \mathrm{id}_G} G \times G \xrightarrow{\circ} G$$

The first equation above is then an equality of these two compositions. The whole equational theory of groups is then a category with finite products whose objects are integers  $0, 1, 2, \ldots$  (representing the objects  $G^0, G^1, G^2, \ldots$ ). The product corresponds to the addition of integers. Every *n*-ary operation corresponds to a morphism from *n* to 1, while morphisms from *n* to *m* correspond to *m*-tuples of *n*-ary operations. For example, there is a morphism  $G \times (G \times G) \to G \times G$  which corresponds to the pair of ternary operations

$$\begin{aligned} (x,y,z) &\mapsto x \\ (x,y,z) &\mapsto y \circ z \end{aligned}$$

Lawvere based his concept of an algebraic theory on these observations: algebraic theories are categories  $\mathcal{T}$  with finite products whose objects are the natural numbers  $0, 1, 2, \ldots$  Algebras are then functors from  $\mathcal{T}$  to the category of sets which preserve finite products. Homomorphisms of algebras are represented by natural transformations.

We now present a more general definition of an algebraic theory and its algebras. See Chapter 11 for Lawvere's original concept of a one-sorted theory, and Chapter 14 for S-sorted theories. In the present chapter we also study basic concepts, such as limits of algebras and representable algebras, and we introduce some of the main examples of algebraic categories.

**1.1 Definition.** An algebraic theory is a small category  $\mathcal{T}$  with finite products. An algebra for the theory  $\mathcal{T}$  is a functor  $A: \mathcal{T} \to Set$  preserving finite products. We denote by  $Alg\mathcal{T}$  the category of algebras of  $\mathcal{T}$ . Morphisms, called *homomorphisms*, are the natural transformations. That is,  $Alg\mathcal{T}$  is a full subcategory of the functor category  $Set^{\mathcal{T}}$ .

**1.2 Definition.** A category is *algebraic* if it is equivalent to AlgT for some algebraic theory T.

**1.3 Remark.** An algebraic theory is by definition a small category. However, throughout the book we do not take care of the difference between *small* and *essentially small*: a category is essentially small if it is equivalent to a small one.

We will see in 10.15, 13.11 and 14.28 that algebraic categories correspond well to varieties, i.e., equational categories of (many-sorted, finitary) algebras.

**1.4 Example.** Sets. The simplest algebraic category is the category of sets itself. An algebraic theory  $\mathcal{N}$  for *Set* can be described as the full subcategory of  $Set^{op}$  whose objects are the natural numbers. In fact, since  $n = 1 \times \ldots \times 1$  in  $Set^{op}$ , every algebra  $A: \mathcal{N} \to Set$  is determined, up to isomorphism, by the set A1. More precisely, we have an equivalence functor

$$E: Alg \mathcal{N} \to Set$$
,  $A \mapsto A1$ .

The category Set has other algebraic theories – we describe them in Chapter 15.

**1.5 Example.** Many-sorted sets. For a fixed set S, the power category Set<sup>S</sup> of S-sorted sets and S-sorted functions is algebraic. A theory for Set<sup>S</sup> can be descrived as the following category

 $S^*$ 

whose objects are finite words over S (including the empty word). Morphisms from  $s_0 \ldots s_{n-1}$  to  $s'_0 \ldots s'_{k-1}$  are functions  $a: k \to n$  such that  $s_{a(i)} = s'_i (i = 0, \ldots, k-1)$ . When S is the terminal set 1, this theory is nothing else than the theory  $\mathcal{N}$  of *Set* described in 1.4. The fact that  $S^*$  is a theory of S-sorted sets will be seen in 1.18.

**1.6 Example.** Abelian groups. An algebraic theory for the category Ab of abelian groups is the category  $\mathcal{T}_{ab}$  having natural numbers as objects, and morphisms from n to k are matrices of integers with n columns and k rows. Composition of  $P: m \to n$  and  $Q: n \to k$  is given by matrix multiplication  $Q \cdot P = Q \times P: m \to k$ , and identity morphisms are the unit matrices. If n = 0 or k = 0 the only  $n \times k$  matrix is the empty one [].  $\mathcal{T}_{ab}$  has finite products. For example, 2 is the product  $1 \times 1$  with projections  $[1,0]: 2 \to 1$  and  $[0,1]: 2 \to 1$ . (In fact, given one-row matrices  $P, Q: n \to 1$ , there exists a unique two-row matrix  $R: n \to 2$  such that  $[1,0] \cdot R = P$  and  $[0,1] \cdot R = Q$ : the matrix with rows P and Q.) Here is a direct argument proving that the category Ab of abelian groups is equivalent to  $Alg \mathcal{T}_{ab}$ . Every abelian group G defines an algebra  $\hat{G}: \mathcal{T}_{ab} \to Set$  in the sense of 1.1 whose object function is  $\hat{G}n = G^n$ . For every morphism  $P: n \to k$  we define  $\hat{G}P: G^n \to G^k$  by matrix multiplication

$$\widehat{G}(P) \colon \left[ \begin{array}{c} g_1 \\ \vdots \\ g_n \end{array} \right] \mapsto P \cdot \left[ \begin{array}{c} g_1 \\ \vdots \\ g_n \end{array} \right]$$

The function  $G \mapsto \widehat{G}$  extends to a functor  $(-): Ab \to Alg \mathcal{T}_{ab}$  in a rather obvious way: given a group homomorphism  $h: G_1 \to G_2$ , then  $\hat{h}: \widehat{G}_1 \to \widehat{G}_2$  is the natural transformation whose components are  $h^n: G_1^n \to G_2^n$ . It is clear that (-) is a well defined, full and faithful functor. To prove that it is an equivalence functor, we need, for every algebra  $A: \mathcal{T}_{ab} \to Set$ , to present an abelian group G with  $A \simeq \widehat{G}$ . The underlying set of G is A1. The binary group operation is obtained from the morphism  $[1, 1]: 2 \to 1$  in  $\mathcal{T}_{ab}$  by  $A[1, 1]: G^2 \to G$ , the neutral element

is  $A[]: 1 \to G$  for the morphism  $[]: 0 \to 1$  of  $\mathcal{T}_{ab}$ , and the inverse is given by  $A[-1]: G \to G$ . It is not difficult to check that the axioms of abelian group are fulfilled. For example, the axiom x+0 = x follows from the fact that A preserves the composition of  $\begin{bmatrix} 1\\0 \end{bmatrix}: 1 \to 2$  with  $[1,1]: 2 \to 1$ . Clearly,  $A \simeq \widehat{G}$  (consider the canonical isomorphism  $An = A(1 \times \ldots \times 1) \simeq A1 \times \ldots \times A1 = G^n = \widehat{G}n$ ).

**1.7 Example.** Groups. As mentioned at the beginning of this chapter, an algebraic theory of groups consists of all derived operations and all equations that hold in all groups. Viewed as an algebraic theory  $\mathcal{T}_{gr}$ , we have, as in the previous example, natural numbers as objects. Morphisms can be described by considering a standard set of variables  $x_0, x_1, x_2, \ldots$  and defining the morphisms from n to 1 in  $\mathcal{T}_{gr}$  to be precisely all terms in the variables  $x_0, \ldots, x_{n-1}$  (see Remark 13.1 for a formal definition of the concept of term). The morphisms from n to k in general are all k-tuples of morphisms in  $\mathcal{T}_{gr}(n, 1)$ . The identity morphism in  $\mathcal{T}_{gr}(n, n)$  is the n-tuple of terms ( $x_0, \ldots, x_{n-1}$ ). And composition is given by substitution of terms. We will see in Chapter 13 the reason why the category of groups is indeed equivalent to  $Alg \mathcal{T}_{gr}$ .

**1.8 Example.** Modules. Let R be a ring with unit. The category R-Mod of left modules and module homomorphisms is algebraic. A theory directly generalizing that of abelian groups above has as objects natural numbers and as morphisms matrices over R. Algebraic categories of the form R-Mod are treated in greater detail in Appendix B.

**1.9 Example.** One-sorted  $\Sigma$ -algebras. Let  $\Sigma$  be a *signature*, that is, a set  $\Sigma$  (of operation symbols) together with an arity function

ar:  $\Sigma \to \mathbb{N}$ .

A  $\Sigma$ -algebra consists of a set A and, for every n-ary symbol  $\sigma \in \Sigma$ , an n-ary operation  $\sigma^A \colon A^n \to A$ . A homomorphism of  $\Sigma$ -algebras is a function preserving the given operations. The category

 $\Sigma$ -Alg

of  $\Sigma$ -algebras and homomorphisms as well as its equational subcategories are algebraic, as we demonstrate in Chapter 13. Clearly, groups and abelian groups enter into this general example, as well as many other classical algebraic structures, like Boolean algebras, Lie algebras, and so on.

**1.10 Example.** Many-sorted  $\Sigma$ -algebras. Let S be a set (of sorts). An S-sorted signature is a set  $\Sigma$  (of operation symbols) together with an arity function

$$\operatorname{ar}\colon \Sigma \to S^* \times S$$

where  $S^*$  is the set of all finite words on S. We write  $\sigma: s_1 \dots s_n \to s$  for an operation symbol  $\sigma$  of arity  $(s_1 \dots s_n, s)$ . In case n = 0 we write  $\sigma: s$ . (In 1.5)

we have used the symbol  $S^*$  above to denote a category. But there is no danger of confusion: it will always be clear from the context whether we mean the category  $S^*$  or just the set of its objects.) A  $\Sigma$ -algebra consists of an S-sorted set  $A = \langle A_s \rangle_{s \in S}$  and, for every symbol  $\sigma \in \Sigma$  of arity  $(s_1 \dots s_n, s)$ , an operation  $\sigma^A \colon A_{s_1} \times \dots \times A_{s_n} \to A_s$ . Homomorphisms of  $\Sigma$ -algebras are S-sorted functions (that is, morphisms of Set<sup>S</sup>) preserving the given operations. The category

 $\Sigma$ -Alg

of  $\Sigma$ -algebras and homomorphisms is equational. And so are all equational subcategories, as we demonstrate in Chapter 14. Here is a concrete example:

**1.11 Example.** Graphs. We denote by *Graph* the category of *directed graphs* G with multiple edges: they are given by a set  $G_v$  of vertices, a set  $G_e$  of edges, and two functions from  $G_e$  to  $G_v$  determining the target  $(\tau)$  and the source  $(\sigma)$  of every edge. The morphisms are called *graph homomorphisms*: given graphs G and G' a graph homomorphism is a pair of functions  $h_v \colon G_v \to G'_v$  and  $h_e \colon G_e \to G'_e$  such that the source and the target of every edge is preserved. A theory for *Graph* will be described in 1.16.

**1.12 Remark.** Every object t of an algebraic theory  $\mathcal{T}$  yields the algebra  $Y_{\mathcal{T}}(t)$  representable by t:

$$Y_{\mathcal{T}}(t) = \mathcal{T}(t, -) \colon \mathcal{T} \to Set.$$

Following 0.4, this and the Yoneda transformations define a full and faithful functor

$$Y_{\mathcal{T}}: \mathcal{T}^{op} \to Alg \mathcal{T}$$
.

**1.13 Lemma.** For every algebraic theory  $\mathcal{T}$ , the Yoneda embedding

$$Y_{\mathcal{T}} \colon \mathcal{T}^{op} \to Alg \mathcal{T}$$

preserves finite coproducts.

**Proof.** If 1 is a terminal object of  $\mathcal{T}$  then  $\mathcal{T}(1, -)$  is an initial object of  $Alg\mathcal{T}$ : for every algebra A we know that A1 is a terminal object, thus there is a unique morphism  $\mathcal{T}(1, -) \to A$ .

Given two objects  $t_1, t_2$  in  $\mathcal{T}$  then  $\mathcal{T}(t_1 \times t_2, -)$  is a coproduct of  $\mathcal{T}(t_1, -)$  and  $\mathcal{T}(t_2, -)$  since for every algebra A the morphisms  $\mathcal{T}(t_1 \times t_2, -) \to A$  correspond to elements of  $A(t_1 \times t_2) = A(t_1) \times A(t_2)$ .

**1.14 Example.** Set-valued functors. If C is a small category, the functor category  $Set^{C}$  is algebraic. An algebraic theory of  $Set^{C}$  is a *free completion*  $\mathcal{T}_{C}$  of C under finite products. This means a functor  $E_{Th}: C \to \mathcal{T}_{C}$  such that

1.  $\mathcal{T}_{\mathcal{C}}$  is a category with finite products

and

2. for every functor  $F: \mathcal{C} \to \mathcal{B}$ , where  $\mathcal{B}$  is a category with finite products, there exists an essentially unique functor (that is, unique up to natural isomorphism)  $F^*: \mathcal{T}_{\mathcal{C}} \to \mathcal{B}$  preserving finite products with F naturally isomorphic to  $F^* \cdot E_{Th}$ .

In other words, composition with  $E_{Th}$  gives an equivalence between the category of finite product preserving functors from  $\mathcal{T}_{\mathcal{C}}$  to  $\mathcal{B}$  and the category of functors from  $\mathcal{C}$  to  $\mathcal{B}$ . In particular, the categories Set  $^{\mathcal{C}}$  and Alg  $\mathcal{T}_{\mathcal{C}}$  are equivalent.

#### 1.15 Remark.

1. The free finite-product completion  $\mathcal{T}_{\mathcal{C}}$  can be described as follows: objects of  $\mathcal{T}_{\mathcal{C}}$  are all finite families

$$(C_i)_{i \in I}, I \text{ finite}$$

of objects of  $\mathcal{C}$ , and morphisms from  $(C_i)_{i \in I}$  to  $(C'_j)_{j \in J}$  are pairs  $(a, \alpha)$ where  $a: J \to I$  is a function and  $\alpha = (\alpha_j)_{j \in J}$  is a family of morphisms  $\alpha_j: C_{a(j)} \to C'_j$  of  $\mathcal{C}$ . The composition and identity morphisms are defined as expected. A terminal object in  $\mathcal{T}_{\mathcal{C}}$  is the empty family, and a product of two objects is the disjoint union of the families. Finally, the functor  $E_{Th}: \mathcal{C} \to \mathcal{T}_{\mathcal{C}}$  is given by  $E_{Th}(C) = (C)$ . It is easy to verify the universal property: since for every object  $(C_i)_{i \in I}$  in  $\mathcal{T}_{\mathcal{C}}$  we have  $(C_i)_{i \in I} = \prod_I E_{Th}(C_i)$ , then necessarily  $F^*((C_i)_{i \in I}) = \prod_I FC_i$ .

2. Equivalently,  $\mathcal{T}_{\mathcal{C}}$  can be described as the category of all words over  $\operatorname{obj} \mathcal{C}$ (the set of objects of  $\mathcal{C}$ ). That is, objects have the form of *n*-tuples  $C_0 \ldots C_{n-1}$  where each  $C_i$  is an object of  $\mathcal{C}$  (and where *n* is identified with the set  $\{0, \ldots, n-1\}$ ) including the case n = 0 (empty word). Morphisms from  $C_0 \ldots C_{n-1}$  to  $C'_0 \ldots C'_{k-1}$  are pairs  $(a, \alpha)$  consisting of a function  $a: k \to n$  and a k-tuple of  $\mathcal{C}$ -morphisms  $\alpha = (\alpha_0, \ldots, \alpha_{k-1})$  with  $\alpha_i: C_{a(i)} \to C'_i$ .

**1.16 Example.** The category of graphs, see 1.11, is equivalent to  $Set^{\Rightarrow}$  and its theory  $\mathcal{T}_{graph}$  is the free completion of

$$\operatorname{id}_e \bigcap e \xrightarrow[\sigma]{\quad \sigma} v \bigcap \operatorname{id}_v$$

under finite products.

**1.17 Remark.** Since the Yoneda embedding  $Y_{\mathcal{T}_{\mathcal{C}}}: \mathcal{T}_{\mathcal{C}}^{op} \to Alg \mathcal{T}_{\mathcal{C}} \simeq Set^{\mathcal{C}}$  preserves finite coproducts (1.13), the category  $\mathcal{T}_{\mathcal{C}}^{op}$  is equivalent to the full subcategory of  $Set^{\mathcal{C}}$  given by finite coproducts of representable functors.

#### 1.18 Example.

1. The algebraic theory  $\mathcal{N}$  for *Set* described in 1.4 is nothing else than the theory  $\mathcal{T}_{\mathcal{C}}$  of 1.14 when  $\mathcal{C}$  is the one-object discrete category.

2. More generally, if in 1.14 the category C is discrete, i.e. it is a set S,  $\mathcal{T}_C$  is the theory  $S^*$  for S-sorted sets described in 1.5. Following 1.17,  $S^*$  is equivalent to the full subcategory of  $Set^S$  of *finite S-sorted sets* (an S-sorted set  $\langle A_s \rangle_{s \in S}$  is finite if the coproduct  $\prod_S A_s$  is a finite set).

**1.19 Example.** Another special case of Example 1.14 is the category M-Set of M-sets for M a monoid: if we consider M as a one-object category whose morphisms are the elements of M, then M-Set is equivalent to  $Set^M$ . As we will see in 13.15, M-Set is a category of unary algebras. More generally, the category  $Set^{\mathcal{C}}$  can be presented as a category of unary S-sorted algebras: choose  $S = obj\mathcal{C}$  as set of sorts,  $\Sigma = mor\mathcal{C}$  as set of operation symbols, and define ar(f) = (s, s') if  $f \in \mathcal{C}(s, s')$ . Then  $Set^{\mathcal{C}}$  is equivalent to the subcategory of  $\Sigma$ -Alg of those algebras satisfying the equations

$$u(v(x)) = (uv)(x) (u, v \text{ composable morphisms of } C)$$

and

$$\operatorname{id}_s(x) = x \ (s \in S).$$

#### 1.20 Remark.

- 1. In the example of abelian groups we have the forgetful functor  $U: Ab \rightarrow$ Set assigning to every abelian group its underlying set. Observe that the groups  $\mathbb{Z}^n$  are free objects of Ab on n generators, and the full subcategory of all these objects is the dual of the theory  $\mathcal{T}_{ab}$  in 1.6.
- 2. Analogously, if the category C of Example 1.14 has the object set S, then we have a forgetful functor which forgets the action of  $A: C \to Set$  on morphisms:

$$U: Set^{\mathcal{C}} \to Set^{S}, \quad UA = \langle A(s) \rangle_{s \in S}.$$

That functor U has a left adjoint

$$F: Set^{S} \to Set^{\mathcal{C}}, \quad F(\langle A_s \rangle_{s \in S}) = \prod_{s \in S} \left( \prod_{A_s} \mathcal{C}(s, -) \right)$$

(this easily follows from the Yoneda Lemma because F preserves coproducts). Following 1.17, the objects of the theory  $\mathcal{T}_{\mathcal{C}}$  are precisely the finitely generated free objects, that is, the image of finite S-sorted sets under F.

3. In Chapters 11 and 14 we will see that this is not a coincidence: for every S-sorted algebraic category  $\mathcal{A}$  the free objects on finite S-sorted sets form a full subcategory whose dual is a theory for  $\mathcal{A}$  (see 11.22 for one-sorted algebraic categories and 14.13 for S-sorted algebraic categories).

The category of algebras of an algebraic theory is quite rich. We already know that every object t of an algebraic theory  $\mathcal{T}$  yields the representable algebra  $Y_{\mathcal{T}}(t) = \mathcal{T}(t, -)$ . Other examples of algebras can be obtained e.g. by the formation of limits and colimits. We will now show that limits always exist and are built up at the level of sets. Also colimits always exist, but they are seldom built up at the level of sets. We will study colimits in the subsequent chapters.

**1.21 Proposition.** For every algebraic theory  $\mathcal{T}$ , the category  $Alg\mathcal{T}$  is closed in Set<sup> $\mathcal{T}$ </sup> under limits.

**Proof.** Limits are formed objectwise in  $Set^{\mathcal{T}}$ . Since limits and finite products commute (0.5), given a diagram in  $Set^{\mathcal{T}}$  whose objects are functors preserving finite products, then a limit of that diagram also preserves finite products.  $\Box$ 

1.22 Corollary. Every algebraic category is complete.

#### 1.23 Remark.

- 1. The previous proposition means that limits of algebras are formed objectwise at the level of sets. For example, a product of two graphs has both the vertex set given by the cartesian product of the vertex sets, and the set of edges given by the cartesian product of the edge sets.
- 2. Monomorphisms in the category  $Alg\mathcal{T}$  are precisely the homomorphisms that are componentwise monomorphisms (i.e., injective functions) in *Set*. In fact, this is true in  $Set^{\mathcal{T}}$ , and  $Alg\mathcal{T}$  is closed under monomorphisms (being closed under limits) in  $Set^{\mathcal{T}}$ .
- 3. In every algebraic category kernel pairs (0.15) exist and are formed objectwise (in *Set*).

**1.24 Example.** One of the most important data types in computer science is a stack, or finite list, of elements of a set (of "letters") called an alphabet. Here we consider stacks of natural numbers: we will have elements of sort n (natural number) and s (stack) and the following two-sorted signature:

succ :  $n \to n$ , the successor of a natural number,

push :  $sn \to n$ , which adds a new letter to the left-most position of a stack,

pop :  $s \to s$ , which deletes the left-most position,

and

top :  $s \to n$ , which reads the top element of the stack.

We will also have two constants: e: s, for the empty stack, and 0: n. For simplicity we put top(e) = 0.

This leads us to the concept of algebras A of two sorts

s (stack) and n (natural number)

with operations

suce :  $A_n \to A_n$ ,

push :  $A_s \times A_n \to A_s$ ,

pop :  $A_s \to A_s$ ,

and

top :  $A_s \to A_n$ ,

and with constants  $0 \in A_n$  and  $e \in A_s$ .

We can consider stacks as equationally specified algebras of sorts  $\{s, n\}$ , and the algebraic theory is then obtained from the corresponding finitely generated free algebras.

**1.25 Example.** Sequential automata. Recall that a deterministic sequential automaton A is given by a set  $A_s$  of states, a set  $A_i$  of input symbols, a set  $A_o$  of output symbols, and by three functions

$$\begin{split} &\delta \colon A_s \times A_i \to A_s \text{ (next-state function)} \\ &\gamma \colon A_s \to A_o \text{ (output)} \\ &\varphi \colon 1 \to A_s \text{ (initial state)} \end{split}$$

Given two sequential automata A and  $A' = (A'_s, A'_i, A'_o, \delta', \gamma', \varphi')$ , a morphism (simulation) is given by a triple of functions

$$h_s \colon A_s \to A'_s, \ h_i \colon A_i \to A'_i, \ h_o \colon A_o \to A'_o$$

such that the diagram

$$\begin{array}{c|c} A_s \times A_i & \xrightarrow{\delta} & A_s \xrightarrow{\gamma} & A_o \\ & & & & & \\ h_s \times h_i & & & & \\ & & & & & \\ & & & & & \\ A'_s \times A'_i & \xrightarrow{\delta'} & A'_s & \xrightarrow{\gamma'} & A'_o \end{array}$$

commutes. This is the category of algebras of three sorts s, i and o, given by the signature

$$\delta \colon si \to s \;, \quad \gamma \colon s \to o \;, \quad \varphi \colon s \;.$$

Again, an algebraic theory of automata is formed by considering finitely generated free algebras.

#### Historical Remarks for Chapter 1

Algebraic theories were introduced by F. W. Lawvere in his dissertation [60]. He considered the one-sorted case, which we study in Chapter 11. This corresponds to (one-sorted) equational theories of G. Birkhoff [25] which we treat in Chapter 13.

#### CHAPTER 1. ALGEBRAIC THEORIES AND ALGEBRAIC CATEGORIES

Many-sorted equational theories were first considered by P. J. Higgins [50] and were later popularized by G. Birkhoff and J. D. Lipson [26]. In the review of Higgins' paper A. Heller [49] suggested to look for the connection with Lawvere's approach. This was done by J. Bénabou [23] who dealt with many-sorted algebraic theories. Our definition of an algebraic theory is given without a reference to sorting. This "sort-free" approach corresponds to the more general theory of sketches initiated by C. Ehresmann [40] (see [22] for an exposition). The S-sorted approach is presented in Chapter 14.

The interested reader can find expositions of various aspects of algebraic theories e.g. in the following literature:

finitary theories and their algebras in general categories, see [51], [28], [19], [74], [87] or [77],

infinitary theories, see [63] and [97],

applications of theories in computer science, see [20] and [96].

The book [71] of E. G. Manes is, in spite of its title, devoted to monads, not theories; an introduction to monads can be found in Appendix A of our book.

### Chapter 2

## Sifted and filtered colimits

Colimits in algebraic categories are, in general, not formed objectwise. In this chapter we study the important case of sifted colimits, which are always formed objectwise. Prominent examples of sifted colimits are filtered colimits and reflexive coequalizers (see Chapter 3).

**2.1 Definition.** A small category  $\mathcal{D}$  is called

- 1. *sifted* if finite products in *Set* commute with colimits over  $\mathcal{D}$ .
- 2. *filtered* if finite limits in *Set* commute with colimits over  $\mathcal{D}$ .

Sifted (or filtered) diagrams are diagrams with a sifted (or filtered) domain. Colimits of sifted (or filtered) diagrams are called sifted (or filtered) colimits.

#### 2.2 Remark.

1. Explicitly, a small category  $\mathcal{D}$  is sifted iff, given a diagram

,

$$D: \mathcal{D} \times \mathcal{J} \to Set$$

where  $\mathcal{J}$  is a finite discrete category, then the canonical map

$$\delta: \quad \underset{\mathcal{D}}{\text{colim}} \quad \left(\prod_{\mathcal{J}} D(d,j)\right) \to \prod_{\mathcal{J}} (\begin{array}{cc} colim \\ \mathcal{D} \end{array} D(d,j)) \quad [2.1]$$

is an isomorphism.  $\mathcal{D}$  is filtered iff it satisfies the same condition, but with respect to every finitely generated category  $\mathcal{J}$  (replace  $\prod_{\mathcal{J}}$  by  $\lim_{\mathcal{J}}$ in [2.1]).

2. The canonical map  $\delta$  in [2.1] is an isomorphism for every finite discrete category  $\mathcal{J}$  iff  $\delta$  is an isomorphism when  $\mathcal{J}$  is the empty set and when  $\mathcal{J}$  is the two-element set. The latter means that for every pair  $D, D': \mathcal{D} \to Set$  of diagrams the colimit of

 $D \times D' : \mathcal{D} \times \mathcal{D} \to Set$ ,  $(d, d') \mapsto Dd \times D'd'$ 

is canonically isomorphic to  $\operatorname{colim} D \times \operatorname{colim} D'$ .

#### 2.3 Example.

- 1. Colimits of  $\omega$ -chains are filtered. Here the category  $\mathcal{D}$  is the poset of natural numbers, considered as a category.
- 2. More generally, colimits of chains (where  $\mathcal{D}$  is an infinite ordinal considered as a poset) are filtered. These are the "typical" filtered colimits: a category having colimits of chains has all filtered colimits, see 1.5 and 1.7 in [8].
- 3. Generalizing still further: *directed colimits* are filtered. Recall that a poset is called (upwards) directed if it is nonempty and every pair of elements has an upper bound. Directed colimits are colimits of diagrams whose schemes are directed posets.
- 4. An example of filtered colimits that are not directed: the colimits of idempotents. Let f be an endomorphism of an object A which is idempotent, that is,  $f \cdot f = f$ . This can be considered as a diagam whose domain  $\mathcal{D}$  has one object and, besides the identity, precisely one idempotent morphism. This category is filtered. In fact, the colimit of the above diagram is the coequalizer of f and  $id_A$ . It is not difficult to verify directly (or using 2.19) that in *Set* these coequalizers commute with finite limits. We return to colimits of idempotents in Chapter 8: they are precisely the splitting of idempotents studied there.

There exist, essentially, no other finite filtered colimits than colimits of idempotents. In fact, whenever a finite category  $\mathcal{D}$  is filtered, then it has a cone  $f_X: Z \to X$  ( $X \in \operatorname{obj} \mathcal{D}$ ) over itself. It follows easily that  $f_Z: Z \to Z$  is an idempotent, and a colimit of a diagram  $D: \mathcal{D} \to \mathcal{A}$  exists iff the idempotent  $Df_Z$  has a colimit in  $\mathcal{A}$ .

- 5. Filtered colimits are of course sifted.
- 6. Coequalizers are colimits that are not sifted (see 2.17). As we will see in Chapter 3, reflexive coequalizers are sifted (but not filtered); these are coequalizers of parallel pairs  $a_1, a_2 \colon A \rightrightarrows B$  for which  $d \colon B \to A$  exists with  $a_1 \cdot d = \mathrm{id}_B = a_2 \cdot d$ .

In fact, in a sense made precise in Chapter 7, we can state that

sifted colimits = filtered colimits + reflexive coequalizers.

2.4 Remark. Sifted categories have an easy characterization: they

(i) are nonempty

and

(ii) have, for every pair of objects, the category of all cospans connected.

This will be proved in 2.15. Before doing that, we need to recall the standard concepts of connected category and final functor. But we first present a result showing why sifted colimits are important.

February 1, 2010 22

**2.5 Proposition.** For every algebraic theory  $\mathcal{T}$ , the category  $Alg\mathcal{T}$  is closed in Set  $^{\mathcal{T}}$  under sifted colimits.

**Proof.** Since sifted colimits and finite products commute in *Set*, they do so in *Set*<sup> $\mathcal{T}$ </sup> (where they are computed objectwise). It follows that a sifted colimit in *Set*<sup> $\mathcal{T}$ </sup> of functors preserving finite products also preserves finite products.  $\Box$ 

**2.6 Example.** Coproducts are not sifted colimits. In fact, for almost no algebraic theory  $\mathcal{T}$  is  $Alg\mathcal{T}$  closed under coproducts in  $Set^{\mathcal{T}}$ . Concrete example: if  $\mathcal{T}_{ab}$  is the theory of abelian groups (1.6), then binary coproducts in  $Alg\mathcal{T}_{ab}$  are products and in  $Set^{\mathcal{T}_{ab}}$  they are disjoint union.

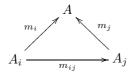

**2.7 Corollary.** In every algebraic category sifted colimits commute with finite products.

In fact, this follows from the fact that the category  $Alg\mathcal{T}$  is closed under limits and sifted colimits in  $Set^{\mathcal{T}}$  and such limits and colimits in  $Set^{\mathcal{T}}$  are formed objectwise.

2.8 Example. In the category of abelian groups

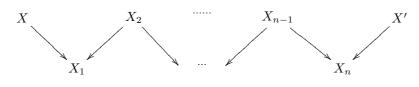

- 1. a directed union of abelian groups carries a canonical structure of abelian group: the directed colimit of the diagram of inclusion homomorphisms,
- 2. let  $a_1, a_2: A \Rightarrow B$  be a pair of homomorphisms with a common splitting  $d: B \to A$  (i.e.,  $a_1 \cdot d = \mathrm{id}_B = a_2 \cdot d$ ) and let  $c: B \to C$  be its coequalizer in *Set.* The set *C* carries a canonical structure of abelian group (the unique one for which *c* is a homomorphism). Reflexive coequalizers will be studied in detail in Chapter 3.

**2.9 Remark.** Generalizing 2.8.1, a *directed union* in  $Alg\mathcal{T}$  is a directed colimit of subalgebras. That is, an algebra A is a directed union of subalgebras  $m_i: A_i \to A \ (i \in I)$  provided that the poset on I given by  $i \leq j$  iff  $m_i \subseteq m_j$  is directed and A is the colimit (with colimit cocone  $m_i$ ) of the directed diagram of all  $A_i, i \in I$  and all connecting morphisms  $m_{ij}$ :

Thus  $Alg \mathcal{T}$  is closed under directed unions in  $Set^{\mathcal{T}}$ .

**2.10 Definition.** A category  $\mathcal{A}$  is called *connected* if it is nonempty and for every pair of objects X and X' in  $\mathcal{A}$  there exists a zig-zag of morphisms connecting X and X':

This is equivalent to saying that  $\mathcal{A}$  cannot be decomposed as a coproduct (that is, disjoint union) of two nonempty subcategories.

**2.11 Remark.** A small category  $\mathcal{A}$  is connected iff the constant functor  $\mathcal{A} \rightarrow Set$  of value 1 has colimit 1.

**2.12 Definition.** A functor  $F: \mathcal{D}' \to \mathcal{D}$  is called *final* if, for every diagram  $D: \mathcal{D} \to \mathcal{A}$  such that  $colim(D \cdot F)$  exists in  $\mathcal{A}$ , then colimD exists and the canonical morphism  $colimD \cdot F \to colimD$  is an isomorphism.

**2.13 Lemma.** The following conditions on a functor  $F: \mathcal{D}' \to \mathcal{D}$  are equivalent:

- 1. F is final;
- 2. F satisfies the finality condition with respect to all representable functors  $D = \mathcal{D}(d, -);$
- 3. For every object d of  $\mathcal{D}$ , the slice category  $d \downarrow F$  of all morphisms  $d \to Fd'$ ,  $d' \in \operatorname{obj} \mathcal{D}'$ , is connected.

**Proof.**  $1 \Rightarrow 2$  is trivial and  $2 \Rightarrow 3$  follows from the usual description of colimits in *Set* (see 0.6) and the fact that since the diagram  $\mathcal{D}(d, -)$  has colimit 1 (see 0.10), so does the diagram  $\mathcal{D}(d, F-) = \mathcal{D}(d, -) \cdot F$ .

To prove  $3 \Rightarrow 1$ , let  $D: \mathcal{D} \to \mathcal{A}$  be a diagram and let  $c_{d'}: D(Fd') \to C$   $(d' \in \operatorname{obj} \mathcal{D}')$  be a colimit of  $D \cdot F$ . For every object d of  $\mathcal{D}$ , choose a morphism  $u_d: d \to Fd'$  for some  $d' \in \operatorname{obj} \mathcal{D}'$ , and put  $g_d = c_{d'} \cdot Du_d: Dd \to C$ . We claim that  $g_d: Dd \to C$   $(d \in \operatorname{obj} \mathcal{D})$  is a colimit of D. In fact, since  $d \downarrow F$  is connected, it is easy to verify that  $g_d$  does not depend on the choice of d' and  $u_d$ , and that these morphisms form a cocone of D. The rest of the proof is straightforward.

**2.14 Remark.** Following 2.13 the finality of the diagonal functor  $\Delta$  means that for every pair of objects A, B of  $\mathcal{D}$  the category  $(A, B) \downarrow \Delta$  of cospans on A, B is connected. That is:

- (i) a cospan  $A \to X \leftarrow B$  exists, and
- (ii) every pair of cospans on A, B is connected by a zig-zag of cospans.

Therefore, the statement

 $\mathcal{D}$  is nonempty and the diagonal functor  $\Delta$  is final

is equivalent to the statement

 $\mathcal{D}$  is connected and the diagonal functor  $\Delta$  is final.

**2.15 Theorem.** A small category  $\mathcal{D}$  is sifted if and only if it is nonempty and the diagonal functor  $\Delta: \mathcal{D} \to \mathcal{D} \times \mathcal{D}$  is final.

**Proof.** We are going to prove that  $\mathcal{D}$  is sifted iff it is connected and the diagonal functor  $\Delta$  is final. More precisely, we are going to prove that

1.  $\mathcal{D}$  is connected iff the canonical map  $\delta$  (see 2.2) is an isomorphism when  $\mathcal{J}$  is the empty set,

and

2.  $\Delta$  is final iff the canonical map  $\delta$  is an isomorphism when  $\mathcal{J}$  is the twoelement set (that is, binary products in *Set* commute with colimits over  $\mathcal{D}$ ).

1. When  $\mathcal{J}$  is the empty set the codomain of  $\delta$  is 1 whereas its domain is 1 iff  $\mathcal{D}$  is connected (see 2.11).

2. Let  $\mathcal J$  be the two-element set. Given diagrams  $D,D'\colon \mathcal D\to \mathit{Set},$  consider the functor

$$D \times D' : \mathcal{D} \times \mathcal{D} \to Set$$
,  $(d, d') \mapsto Dd \times D'd'$ .

Since, for every set X, the functor  $X \times -: Set \to Set$  preserves colimits (see 0.11), the colimit of the diagram  $D \times D'$  is

$$\underset{\mathcal{D}\times\mathcal{D}}{\operatorname{colim}} (Dd \times D'd') \simeq \operatorname{colim}_{d \in \mathcal{D}} (\operatorname{colim}_{d' \in \mathcal{D}} (Dd \times D'd')) \simeq \operatorname{colim}_{d \in \mathcal{D}} Dd \times \operatorname{colim}_{d' \in \mathcal{D}} D'd'.$$

Consider now the following commutative diagram of canonical maps

$$\begin{array}{ccc} \operatorname{colim} & (Dd \times D'd) & & & \\ & & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & &$$

If  $\Delta$  is final, then  $\beta$  is an isomorphism and therefore  $\delta$  is also an isomorphism.

Conversely, assume that  $\delta$  is an isomorphism. Given two objects d and d' in  $\mathcal{D}$ , the representable functor  $(\mathcal{D} \times \mathcal{D})((d, d'), -)$  is nothing but  $\mathcal{D} \times \mathcal{D}' : \mathcal{D} \times \mathcal{D} \to Set$ , with  $\mathcal{D} = \mathcal{D}(d, -)$  and  $\mathcal{D}' = \mathcal{D}(d', -)$ . If  $\delta$  is an isomorphism, the previous diagram shows that  $\Delta$  satisfies the finality condition with respect to all representable functors. Following 2.13,  $\Delta$  is final.

**2.16 Example.** Every small category with finite coproducts is sifted. In fact, it contains an initial object, and the slice category  $(A, B) \downarrow \Delta$  is connected because it has an initial object (the coproduct of A and B).

**2.17 Example.** Consider the category  $\mathcal{D}$  given by the morphisms

$$A \xrightarrow{f} B$$

(identity morphisms are not depicted).  $\mathcal{D}$  is not sifted. In fact, the slice category  $(A, B) \downarrow \Delta$  is the discrete category with objects  $(f, \mathrm{id}_B)$  and  $(g, \mathrm{id}_B)$ .

**2.18 Remark.** Filtered colimits are closely related to sifted ones. In fact, our definition in 2.1 stresses this fact. The more usual definition of filtered category  $\mathcal{D}$  is to say that every finitely generated subcategory of  $\mathcal{D}$  has a cocone in  $\mathcal{D}$ . (This includes the condition that  $\mathcal{D}$  is nonempty.) And a well-known result states that this implies the property of Definition 2.1.2. The converse is also true:

**2.19 Theorem.** For a small category  $\mathcal{D}$  the following conditions are equivalent:

- 1.  $\mathcal{D}$  is filtered,
- 2. every finitely generated subcategory of  $\mathcal{D}$  has a cocone,

and

- 3.  $\mathcal{D}$  is nonempty and fulfils
  - (a) for every pair of object A, B there exists a cospan  $A \to X \leftarrow B$ , and
  - (b) for every parallel pair of morphisms  $u, v: A \rightrightarrows B$  there exists a morphism  $f: B \rightarrow C$  merging u and  $v: f \cdot u = f \cdot v$ .

**Proof.** The proof of the implications  $3 \Leftrightarrow 2 \Rightarrow 1$  is standard, the reader can find it e.g. in [28], Vol. 1, Theorem 2.13.4. The proof of the implication  $1 \Rightarrow 3$  is easy: for (a) argue as in 2.15, for (b) use, analogously, the equalizer of  $\mathcal{D}(u, -), \mathcal{D}(v, -) : \mathcal{D}(B, -) \Rightarrow \mathcal{D}(A, -)$  which is the diagram D of all morphisms merging u and v: since colim D = 1 the diagram is nonempty.

With the next proposition we establish a further analogy to 2.15:

**2.20 Proposition.** A small category  $\mathcal{D}$  is filtered if and only if for any finitely generated category  $\mathcal{J}$  the diagonal functor  $\Delta \colon \mathcal{D} \to \mathcal{D}^{\mathcal{J}}$  is final.

**Proof.** 1. Let all such functors  $\Delta$  be final. We are to show that every finitely generated subcategory  $\mathcal{J}$  of  $\mathcal{D}$  has a cocone in  $\mathcal{D}$ . The inclusion functor  $d: \mathcal{J} \to \mathcal{D}$  is an object of the functor category  $\mathcal{D}^{\mathcal{J}}$ . Following 2.13.3, the slice category  $d \downarrow \Delta$  is connected, thus, nonempty. Since  $d \downarrow \Delta$  is precisely the category of cocones of  $\mathcal{J}$  in  $\mathcal{D}$ , we obtain the desired cocone.

2. Conversely, let  $\mathcal{D}$  be filtered. We are to verify that for every object d of  $\mathcal{D}^{\mathcal{J}}$ , where  $\mathcal{J}$  is finitely generated, the slice category  $d \downarrow \Delta$  is connected.

2a. If  $\mathcal{J}$  is a subcategory of  $\mathcal{D}$  and  $d: \mathcal{J} \to \mathcal{D}$  is the inclusion functor, then the category  $d \downarrow \Delta$  of all cocones is nonempty. To prove that it is in fact connected, consider two cocones  $C_1$  and  $C_2$ . Since  $\mathcal{J}$  is finitely generated (say, by a finite set M of morphisms), it has finitely many objects, thus,  $C_1$  and  $C_2$  are finite sets of morphisms. Put  $\overline{M} = M \cup C_1 \cup C_2$  and let  $\overline{\mathcal{J}}$  be the subcategory of  $\mathcal{D}$  generated by  $\overline{M}$ . Then  $\overline{\mathcal{J}}$  has a cocone in  $\mathcal{D}$ , and this cocone defines an obvious cocone of  $\mathcal{J}$  with cocone morphisms to  $C_1$  and  $C_2$ . Thus, we obtain a zig-zag of length 2.

2b. Let  $d: \mathcal{J} \to \mathcal{D}$  be arbitrary and let M be a finite set of morphisms generating  $\mathcal{J}$ . Then the set

$$d(M) \cup \{ \mathrm{id}_{d(x)} ; x \in \mathrm{obj} \mathcal{J} \}$$

is finite and generates a subcategory  $\mathcal{J}_0$  of  $\mathcal{D}$ . The slice category  $d \downarrow \Delta$  is clearly equivalent to the category of cocones of  $\mathcal{J}_0$  in  $\mathcal{D}$  which is connected by 2a.  $\Box$ 

**2.21 Remark.** Every colimit can be expressed as a filtered colimit of finite colimits. That is, given a diagram  $D: \mathcal{D} \to \mathcal{A}$  with  $\mathcal{A}$  cocomplete, then *colim* D can be constructed as the filtered colimit of the diagram of all *colim* D' where  $D': \mathcal{D}' \to \mathcal{A}$  ranges over all domain restrictions of D to finitely generated subcategories  $\mathcal{D}'$  of  $\mathcal{D}$ .

**2.22 Remark.** In Chapter 7 we study functors preserving filtered and sifted colimits. In case of endofunctors of *Set* these two properties coincide (see 6.30) but in general the latter one is stronger, see 2.26. We use the following terminology:

2.23 Definition. A functor is called *finitary* if it preserves filtered colimits.

2.24 Example. Here we mention some endofunctors of Set that are finitary.

1. The functor

$$H_n: Set \to Set \quad H_n X = X^n$$

is finitary for every natural number n since finite products commute in *Set* with filtered colimits.

- 2. A coproduct of finitary functors is finitary.
- 3. Let  $\Sigma$  be a signature (1.9). We define the corresponding *polynomial functor*

$$H_{\Sigma} \colon Set \to Set$$

as the coproduct of the functors  $H_{\operatorname{ar}(\sigma)}$  for  $\sigma \in \Sigma$ . Explicitly,

$$H_{\Sigma}X = \prod_{n \in \mathbb{N}} \Sigma_n \times X^n$$

where  $\Sigma_n$  is the set of all symbols of arity  $n \ (n = 0, 1, 2, ...)$ . This is a finitary functor.

**2.25 Example.** Let  $H: Set \to Set$  be a functor. An *H*-algebra is a pair (A, a) where A is a set and  $a: HA \to A$  a function. A homomorphism from (A, a) to (B, b) is a function  $f: A \to B$  such that the square

$$\begin{array}{c|c} HA \xrightarrow{Hf} HB \\ a \\ a \\ A \xrightarrow{f} B \end{array}$$

commutes. The resulting category is denoted H-Alg.

- 1. In 13.23 we will see that if H is finitary then the category H-Alg is algebraic.
- 2. The special case of a polynomial endofunctor  $H_{\Sigma}$  leads to  $\Sigma$ -algebras. Indeed, for every one-sorted signature  $\Sigma$  the category  $\Sigma$ -Alg is precisely the category  $H_{\Sigma}$ -Alg: if (A, a) is a  $H_{\Sigma}$ -algebra then the operations  $\sigma^A \colon A^n \to A$  are the domain restrictions of a to the summand  $A^n$  corresponding to  $\sigma \in \Sigma_n$ . This case will be treated in Chapter 13.

**2.26 Example.** An example of a finitary functor not preserving sifted colimits is the forgetful functor  $U: Pos \rightarrow Set$ , where Pos is the category of posets and order-preserving maps. Consider the refexive pair  $u, v: 1 + 2 \Rightarrow 2$  from the coproduct of the terminal poset 1 and the two-element chain, where both morphisms are identity on the second summand, and they map the first one to the top and bottom of 2, respectively. Whereas the coequalizer in Pos is given by the terminal poset, the coequalizer of Uu and Uv in Set has two elements.

### Historical Remarks for Chapter 2

Filtered colimits are a natural generalization of directed colimits known from algebra and topology since the beginning of the twentieth century. The general concept can already be found in Bourbaki [30] including the fact that directed colimits commute with finite products in *Set*. Both [45] and [15] contain the general definition of filtered colimits and the fact that they are precisely those colimits which commute with finite limits in *Set*. P. Gabriel and F. Ulmer even speculated about general commutation of colimits with limits in *Set* (see Chapter 15 in [45]) and characterized colimits commuting with finite products in *Set*; this is the source of 2.15. This was later re-discovered by C. Lair [58] who called these colimits "tamisantes". The term sifted was suggested by P. T. Johnstone.

The concept of a final functor and the characterization 2.13 is a standard result of category theory which can be found in [68].

The fact that sifted colimits play an analogous role for algebraic categories that filtered colimits play for the locally finitely presentable ones was presented in [9].

### Chapter 3

# **Reflexive coequalizers**

An important case of sifted colimits are reflexive coequalizers. We will see in Chapter 7 that, in algebraic categories, sifted colimits are just a combination of filtered colimits and reflexive coequalizers. A special case of reflexive coequalizers are coequalizers of equivalence relations which correspond to the classical concept of congruence. It turns out that the step from those classical coequalizers to all reflexive ones makes the theory clearer from the categorical perspective.

**3.1 Definition.** *Reflexive coequalizers* are coequalizers of reflexive pairs, that is, parallel pairs of split epimorphisms having a common splitting.

**3.2 Remark.** In other words, reflexive coequalizers are colimits of diagrams over the category  $\mathcal{M}$  given by the morphisms

$$A \xrightarrow[a_1]{\underbrace{a_1}} B$$

(identity morphisms are not depicted) composed freely modulo  $a_1 \cdot d = \mathrm{id}_B = a_2 \cdot d$ . This category is sifted: it is an easy exercise to check that the categories  $(A, A) \downarrow \Delta$ ,  $(A, B) \downarrow \Delta$  and  $(B, B) \downarrow \Delta$  are connected.

Another method of verifying that  $\mathcal{M}$  is a sifted category is to prove directly that reflexive coequalizers commute in *Set* with binary products. In fact, suppose that

$$A \xrightarrow[a_2]{a_1} B \xrightarrow{c} C \text{ and } A' \xrightarrow[a_2']{a_2'} B' \xrightarrow{c'} C'$$

are reflexive coequalizers in *Set.* We can assume, without loss of generality, that c is the canonical function of the quotient  $C = B / \sim$  modulo the equivalence relation described as follows: two elements  $x, y \in B$  are equivalent iff there

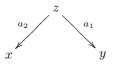

exists a zig-zag

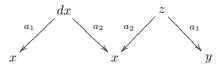

where  $i_1, i_2, \ldots, i_{2k}$  are 1 or 2. For reflexive pairs  $a_1, a_2$  the zig-zags can always be chosen to have the form

(here for the elements  $z_{2i}$  of A we use  $a_1, a_2$  and for the elements  $z_{2i+1}$  we use  $a_2, a_1$ ). In fact, let  $d: B \to A$  be a joint splitting of  $a_1, a_2$ . Given a zig-zag, say,

we can modify it as follows:

Analogously for the general case. Moreover, the length 2k of the zig-zag [3.1] can be prolonged to 2k+2 or 2k+4 etc. by using d. Analogously, we can assume  $C' = B' / \sim'$  where  $\sim'$  is the equivalence relation given by zig-zags of  $a'_1$  and  $a'_2$  of the above form [3.1]. Now we form the parallel pair

$$A \times A' \xrightarrow[a_2 \times a'_2]{a_1 \times a'_1} B \times B'$$

and obtain its coequalizer by the zig-zag equivalence  $\approx$  on  $B \times B'$ . Given  $(x, x') \approx (y, y')$  in  $B \times B'$ , we obviously have zig-zags both for  $x \sim y$  and for  $x' \sim' y'$  (use projections of the given zig-zag). But also the other way round: whenever  $x \sim y$  and  $x' \sim' y'$ , then we choose the two zig-zags so that they both have the above type [3.1] and have the same lengths. They create an obvious zig-zag for  $(x, x') \approx (y, y')$ . From this it follows that the map

$$A \times A' \xrightarrow[a_2 \times a'_2]{a_2 \times a'_2} B \times B' \xrightarrow{c \times c'} (B/\sim) \times (B'/\sim')$$

is a coequalizer, as required.

### CHAPTER 3. REFLEXIVE COEQUALIZERS

**3.3 Corollary.** For every algebraic theory  $\mathcal{T}$ , the category  $Alg\mathcal{T}$  is closed in Set  $^{\mathcal{T}}$  under reflexive coequalizers.

In fact, this follows from 2.5 and 3.2.

**3.4 Example.** In a category with kernel pairs every regular epimorphism is a reflexive coequalizer. In fact, if  $r_1, r_2$  is a kernel pair of a regular epimorphism  $e: A \to B$ 

then e is a coequalizer of  $r_1, r_2$ . And since  $e \cdot id = e \cdot id$ , there exists a unique d with  $r_1 \cdot d = id = r_2 \cdot d$ .

**3.5 Corollary.** For every algebraic theory  $\mathcal{T}$ , the category  $Alg\mathcal{T}$  is closed in  $Set^{\mathcal{T}}$  under regular epimorphisms. Therefore regular epimorphisms in  $Alg\mathcal{T}$  are precisely the homomorphisms which are componentwise epimorphisms (i.e., surjective functions) in Set.

In fact, the first part of the statement follows from 2.5 and 3.4. The second one is clear since the statement is true in  $Set^{\mathcal{T}}$ .

**3.6 Remark.** In particular, every algebraic category is *co-wellpowered* with respect to regular epimorphisms. This means that, for a fixed object A, the regular quotients of A constitute a set (not a proper class). In fact, this is true in *Set* and therefore, by 3.5, in every algebraic category.

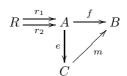

More is true: algebraic categories are co-wellpowered with respect to all epimorphisms. We do not present a proof of this fact here because we do not need it. The interested reader can consult [8], 1.52 and 1.58.

In classical algebra, the "homomorphism theorem" states that every homomorphism can be factorized as a surjective homomorphism followed by the inclusion of a subalgebra. This holds in general algebraic categories:

**3.7 Corollary.** Every algebraic category has regular factorizations, *i.e.*, every morphism is a composite of a regular epimorphism followed by a monomorphism.

**Proof.** The category  $Set^{\mathcal{T}}$  has regular factorizations: given a morphism  $f: A \to B$ , form a kernel pair  $r_1, r_2: R \rightrightarrows A$  and its coequalizer  $e: A \to C$ .

The factorizing morphism m

is a monomorphism. This follows from the fact that kernel pairs and coequalizers are formed objectwise (in *Set*). Since  $Alg\mathcal{T}$  is closed in  $Set^{\mathcal{T}}$  under kernel pairs (1.23) and their coequalizers (3.3), it inherits the regular factorizations from  $Set^{\mathcal{T}}$ .

**3.8 Example.** In Ab we know that:

- 1. Coproducts are not formed at the level of sets. In fact,  $A + B = A \times B$  for all abelian groups A, B.
- 2. Reflexive coequalizers are formed at the level of sets, but general coequalizers are not. Consider e.g. the pair  $x \mapsto 2x$  and  $x \mapsto 0$  of endomorphisms of  $\mathbb{Z}$  whose coequalizer in Ab is finite and in *Set* it is infinite.

**3.9 Remark.** We provided a simple characterization of monomorphisms (1.23) and regular epimorphisms (3.5) in algebraic categories. There does not seem to be a simple characterization of the dual concepts (epimorphisms and regular monomorphisms). In fact, there exist algebraic categories with non-surjective epimorphisms and with non-regular monomorphisms, as we show in the following example.

**3.10 Example.** Monoids. These are algebras with one associative binary operation and one constant which is a neutral element. The category *Mon* of monoids and homomorphisms is algebraic, see 13.14.

An example of an epimorphism which is not regular is the embedding

$$i:\mathbb{Z}\to\mathbb{Q}$$

of the multiplicative monoid of integers into that of rational numbers. In fact, consider monoid homomorphisms  $h, k: \mathbb{Q} \to A$  such that  $h \cdot i = k \cdot i$ . That is, h(n) = k(n) for every integer n. To prove h = k, it is sufficient to verify h(1/m) = k(1/m) for all integers  $m \neq 0$ : this follows from  $h(m) \cdot h(1/m) = k(m) \cdot k(1/m) = 1$  (since h(1) = k(1) = 1). Consequently, i is not a regular epimorphism. Observe that i is also a monomorphism, but not a regular one.

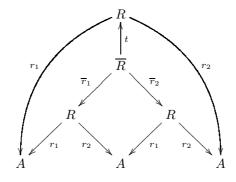

**3.11 Remark.** Recall that in a finitely complete category  $\mathcal{A}$  relations on an object A are the subobjects of  $A \times A$ . A relation can be represented by a monomorphism  $r: R \to A \times A$  or by a parallel pair  $r_1, r_2: R \rightrightarrows A$  of morphisms that are jointly monic. The following definitions generalize the corresponding concepts for relations in *Set*:

**3.12 Definition.** A relation  $r_1, r_2 \colon R \rightrightarrows A$  in a category  $\mathcal{A}$  is called

- 1. reflexive if the pair  $r_1, r_2$  is reflexive  $(r_1 \cdot d = \mathrm{id} = r_2 \cdot d \text{ for some } d \colon A \to R)$ ,
- 2. symmetric if there exists  $s: R \to R$  with  $r_1 = r_2 \cdot s$  and  $r_2 = r_1 \cdot s$

#### and

3. *transitive* provided that for a pullback  $\overline{R}$  of  $r_1$  and  $r_2$  there exists a morphism  $t \colon \overline{R} \to R$  such that the diagram

commutes.

An *equivalence relation* is a relation which is reflexive, symmetric and transitive.

### 3.13 Remark.

- 1. If  $r_1, r_2 : R \rightrightarrows A$  is an equivalence relation, then the morphisms d, s and t of 3.12 are necessarily unique.
- 2. An equivalence relation in *Set* is precisely an equivalence relation in the usual sense.
- 3. Given a relation  $r_1, r_2 \colon R \rightrightarrows A$  and an object X, we can define a relation  $\sim_R$  on the hom-set  $\mathcal{A}(X, A)$  as follows:  $f \sim_R g$  if there exists a morphism  $h \colon X \to R$  such that  $r_1 \cdot h = f$  and  $r_2 \cdot h = g$ . It is easy to check that  $r_1, r_2 \colon R \rightrightarrows A$  is an equivalence relation in  $\mathcal{A}$  iff  $\sim_R$  is an equivalence relation in  $\mathcal{S}et$  for all X in  $\mathcal{A}$ .
- 4. Kernel pairs are equivalence relations.
- 5. In the category of  $\Sigma$ -algebras, see 1.9, an equivalence relation on an algebra A is precisely a subobject of  $A \times A$  which, as a relation on the underlying set of A, is an equivalence relation in *Set*. These relations are usually called congruences on A. We refer to them as equivalence relations in  $\Sigma$ -*Alg* because the concept "congruence" is reserved (with the only exceptions of 11.31 11.33) for congruences of algebraic theories, see Chapter 10.

**3.14 Definition.** A category is said to have *effective equivalence relations* provided that every equivalence relation is a kernel pair.

**3.15 Example.** The category of posets does not have this property: take an arbitrary poset B and an equivalence relation R on the underlying set of B equipped with the discrete ordering, then the two projections  $R \rightrightarrows B$  form an equivalence relation which is seldom a kernel pair.

**3.16 Definition.** A category is called *exact* if it has

- 1. finite limits
- 2. coequalizers of kernel pairs

and

3. effective equivalence relations,

and if

4. regular epimorphisms are stable under pullback. That is, in every pullback

if e is a regular epimorphism, then so is e'.

**3.17 Example.** Set is an exact category. In fact: 1. If  $r_1, r_2: R \rightrightarrows A$  is an equivalence relation, its coequalizer is

$$q: A \to A/\sim_R$$

where  $\sim_R$  is as in 3.13 (with X = 1) and q is the canonical morphism. Clearly,  $r_1, r_2: R \rightrightarrows A$  is a kernel pair of q.

2. Given a pullback as in 3.16 and an element  $x \in B$ , we choose  $z \in C$  with g(x) = e(z) using the fact that e is an epimorphism. Then (x, z) is an element of the pullback A and e'(x, z) = x. This proves that e' is surjective.

**3.18 Corollary.** Every algebraic category is exact.

In fact, since Set is exact, so is Set<sup>S</sup>. Since equivalence relations are reflexive pairs, the exactness of AlgT follows using 1.23 and 3.3.

**3.19 Definition.** We say that colimits in a category  $\mathcal{A}$  distribute over products if given diagrams  $D_i: \mathcal{D}_i \to \mathcal{A} \ (i \in I)$  and forming the diagram

$$D: \prod_{i \in I} \mathcal{D}_i \to \mathcal{A}, \ Dd_i = \prod_{i \in I} D_i d_i$$

then the canonical morphism

$$\operatorname{colim} D \to \prod_{i \in I} \operatorname{colim} D_i$$

is an isomorphism.

If all  $\mathcal{D}_i$  are of a certain type we say that colimits of that type distribute over products.

The concept of distributing over finite products is defined as above but I is required to be finite.

3.20 Example. In the category Set it is easy to verify that

1. filtered colimits distribute over products

and

2. all colimits distribute over finite products.

However reflexive coequalizers do not distribute over infinite products. In fact, consider the coequalizers

$$n+n \xrightarrow{f_n} n+1 \xrightarrow{c_n} 1$$

where the left-hand components of  $f_n$  and  $g_n$  are the inclusion maps  $n \to n+1$ , and the right-hand ones are  $i \mapsto i$  and  $i \mapsto i+1$ , respectively. Then  $\prod_{n \in \mathbb{N}} f_n, \prod_{n \in \mathbb{N}} g_n$  have a coequalizer with infinite codomain, thus, distinct from  $\prod_{n \in \mathbb{N}} c_n$ .

3.21 Corollary. In every algebraic category:

1. Regular epimorphisms are stable under products: given regular epimorphisms  $e_i: A_i \to B_i \ (i \in I)$ , then

$$\prod_{i \in I} e_i \colon \prod_{i \in I} A_i \to \prod_{i \in I} B_i$$

is a regular epimorphism.

- 2. Filtered colimits distribute over products.
- 3. Sifted colimits distribute over finite products.

In fact, since each of the three statements holds in Set, it holds in Set<sup>T</sup>, where limits and colimits are formed objectwise. Following 1.21, 2.5 and 3.5, the statements hold in AlgT for every algebraic theory T.

#### 3.22 Remark.

- 1. In the above corollary we implicitly assume the existence of colimits in an algebraic category. This is not a restriction, because every algebraic category is cocomplete, as we prove in the next chapter.
- 2. Although in *Set* all colimits distribute over finite products, this is not true in algebraic categories in general: consider the empty diagram in the category of unitary rings. For  $I = \{1, 2\}$  in 3.19 and  $\mathcal{D}_1 = \emptyset = \mathcal{D}_2$  we get  $\operatorname{colim} D = \mathbb{Z}$  and  $\operatorname{colim} D_1 \times \operatorname{colim} D_2 = \mathbb{Z} \times \mathbb{Z}$ .

### Historical Remarks for Chapter 3

Reflexive coequalizers were probably first applied by F. E. J. Linton [64]. The fact that they commute with finite products in *Set* (in fact, in every cartesian closed category) is contained in the unpublished thesis of P. T. Johnstone written in the early 1970s. The importance of reflexive coequalizers for algebraic categories was first understood by Y. Diers [38] but his paper remained unnoticed. It was later rediscovered by M. C. Pedicchio and R. Wood [79]. A decisive step was taken in [5] and [6] where reflexive coequalizers were used for establishing the algebraic duality (see Chapter 9) and for the study of abstract "operations", different from limits and filtered colimits, performed in algebraic categories.

Effective equivalence relations were introduced by M. Artin, A. Grothendieck and J. L. Verdier in [15] and exact categories by M. Barr in [18]. The fact that filtered colimits distribute with all products in *Set* goes back to [15].

### Chapter 4

# Algebraic categories as free completions

In this chapter we prove that every algebraic category has colimits. Moreover, the category  $Alg \mathcal{T}$  is a free completion of  $\mathcal{T}^{op}$  under sifted colimits. This shows that algebraic categories can be characterized by their universal property: they are precisely the free sifted-colimit completions of small categories with finite coproducts. This is analogous to the classical result of Gabriel and Ulmer characterizing locally finitely presentable categories as precisely the categories  $Ind\mathcal{C}$  where  $\mathcal{C}$  is a small category with finite colimits and Ind is the free completion under filtered colimits, see 4.12.

**4.1 Remark.** For the existence of colimits, since we already know that AlgT has sifted colimits and, in particular, reflexive coequalizers (see 2.5 and 3.3), all we need to establish is the existence of finite coproducts. Indeed, coproducts then exist because they are filtered colimits of finite coproducts. And coproducts and reflexive coequalizers construct all colimits, see 0.7. The first step towards the existence of finite coproducts has already been done in Lemma 1.13: finite coproducts of representable algebras, including an initial object, exist in AlgT.

In the next lemma we use the category of elements ElA of a functor  $A: \mathcal{T} \to Set$  introduced in 0.14.

**4.2 Lemma.** Given an algebraic theory  $\mathcal{T}$ , for every functor A in Set<sup> $\mathcal{T}$ </sup> the following conditions are equivalent:

1. A is an algebra,

2. ElA is a sifted category

and

3. A is a sifted colimit of representable algebras.

**Proof.**  $2 \Rightarrow 3$ : This follows from 0.14.

 $3 \Rightarrow 1$ : Representable functors are objects of  $Alg \mathcal{T}$  (1.12), and  $Alg \mathcal{T}$  is closed in  $Set^{\mathcal{T}}$  under sifted colimits (2.5).

 $1 \Rightarrow 2$ : Following 2.16, it suffices to prove that  $(ElA)^{op}$  has finite products. This is obvious: for example, the product of (X, x) and (Z, z) is  $(X \times Z, (x, z))$ : recall that  $(x, z) \in AX \times AZ = A(X \times Z)$ .

**4.3 Remark.** An analogous result (with a completely analogous proof) holds for small categories  $\mathcal{T}$  with finite limits: a functor  $A: \mathcal{T} \to Set$  preserves finite limits iff ElA is a filtered category iff A is a filtered colimit of representable functors.

### 4.4 Lemma.

- 1. If two functors  $F: \mathcal{D} \to \mathcal{C}$  and  $G: \mathcal{B} \to \mathcal{A}$  are final, then the product functor  $F \times G: \mathcal{D} \times \mathcal{B} \to \mathcal{C} \times \mathcal{A}$  is final.
- 2. A product of two sifted categories is sifted.

**Proof.** 1. This follows from 2.13.3 because, for any object (d, b) in  $\mathcal{D} \times \mathcal{B}$ , the slice category  $(d, b) \downarrow F \times G$  is nothing but the product category  $(d \downarrow F) \times (b \downarrow G)$ , and the product of two connected categories is connected. 2. Obvious from 1 and 2.15.

**4.5 Theorem.** Every algebraic category is cocomplete.

**Proof.** As explained at the beginning of this chapter, we only need to establish finite coproducts A + B in  $Alg \mathcal{T}$ . Express A as a sifted colimit of representable algebras (4.2)

$$A = colim\left(Y_{\mathcal{T}} \cdot \Phi_A\right)$$

and analogously for B. The category

$$\mathcal{D} = ElA \times ElB$$

is sifted by 4.4 and for the projections  $P_1, P_2$  of  $\mathcal{D}$  we have two colimits in  $Alg \mathcal{T}$  over  $\mathcal{D}$ :

 $A = \operatorname{colim} Y_{\mathcal{T}} \cdot \Phi_A \cdot P_1$  and  $B = \operatorname{colim} Y_{\mathcal{T}} \cdot \Phi_B \cdot P_2$ .

The diagram  $D: \mathcal{D} \to Alg\mathcal{T}$  assigning to every pair (X, x) and (Z, z) a coproduct of the representable algebras (see 1.13)

$$D((X, x), (Z, z)) = Y_{\mathcal{T}} \cdot \Phi_A(x) + Y_{\mathcal{T}} \cdot \Phi_B(z) \quad (\text{in } Alg \mathcal{T})$$

is sifted, thus it has a colimit in  $Alg\mathcal{T}$ . Since colimits over  $\mathcal{D}$  commute with finite coproducts, we get

$$\operatorname{colim} D = \operatorname{colim}_{(x,z)} Y_{\mathcal{T}} \cdot \Phi_A(x) + \operatorname{colim}_{(x,z)} Y_{\mathcal{T}} \cdot \Phi_B(z) = A + B.$$

February 1, 2010

4.6 Example. Coproducts.

1. In the category Ab of abelian groups finite coproducts are finite products: the abelian group  $A \times B$  together with the homomorphisms

$$(-,0): A \to A \times B$$
 and  $(0,-): B \to A \times B$ 

is a coproduct of A and B.

- 2. Infinite coproducts  $\coprod_{i \in I} A_i$  are directed colimits of finite subcoproducts  $\coprod_{j \in J} A_j = \prod_{j \in J} A_j$  (for  $J \subseteq I$  finite).
- 3. In the category of sequential automata (1.25) the product  $A \times B$  of two automata is the machine working simultaneously in A and B on the given (joint) input streams. Whereas the coproduct A + B is the machine working, on a given input streams, completely in A or completely in B.
- 4. A coproduct of graphs in *Graph* is given by the disjoint union of vertices and the disjoint union of edges.

4.7 Example. Coequalizers.

- 1. In Ab a coequalizer of homomorphisms  $f, g: A \Rightarrow B$  is the quotient  $c: B \rightarrow B/B_0$  modulo the subgroup  $B_0 \subseteq B$  of the elements f(a) g(a) for all  $a \in A$ .
- 2. A coequalizer of a parallel pair  $f, g: A \rightrightarrows B$  in *Graph* is given by forming the coequalizers in *Set* of (i) the two vertex functions and (ii) the two edge functions.

**4.8 Remark.** Before characterizing algebraic categories as free completions under sifted colimits, let us recall the general concept of a free completion of a category C: this is, roughly speaking, a cocomplete category A in which C is a full subcategory such that every functor from C to a cocomplete category has an *essentially unique* extension (that is, unique up to natural isomorphism) to a colimit-preserving functor with domain A. In the following definition we say this more precisely. Also, for a given class  $\mathbb{D}$  of small categories we define a free completion under  $\mathbb{D}$ -colimits, meaning that all colimits considered are colimits of diagrams with domains that are elements of  $\mathbb{D}$ .

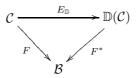

**4.9 Definition.** Let  $\mathbb{D}$  be a class of small categories. By a *free completion of a category*  $\mathcal{C}$  *under*  $\mathbb{D}$ -*colimits* is meant a functor  $E_{\mathbb{D}}: \mathcal{C} \to \mathbb{D}(\mathcal{C})$  such that

1.  $\mathbb{D}(\mathcal{C})$  is a category with  $\mathbb{D}$ -colimits

and

2. for every functor  $F: \mathcal{C} \to \mathcal{B}$ , where  $\mathcal{B}$  is a category with  $\mathbb{D}$ -colimits, there exists an essentially unique functor  $F^*: \mathbb{D}(\mathcal{C}) \to \mathcal{B}$  preserving  $\mathbb{D}$ -colimits

with F naturally isomorphic to  $F^* \cdot E_{\mathbb{D}}$ 

If  $\mathbb{D}$  consists of all small categories, then  $E_{\mathbb{D}} : \mathcal{C} \to \mathbb{D}(\mathcal{C})$  is called a *free completion* of  $\mathcal{C}$  under colimits.

**4.10 Theorem.** For every small category C, the Yoneda embedding

$$Y_{\mathcal{C}^{op}} \colon \mathcal{C} \to Set^{\mathcal{C}^{op}}$$

is a free completion of C under colimits.

**Proof.** The category  $Set^{\mathcal{C}^{op}}$  is of course cocomplete. Let  $F: \mathcal{C} \to \mathcal{B}$  be a functor, where  $\mathcal{B}$  has colimits. Since  $F^*: Set^{\mathcal{C}^{op}} \to \mathcal{B}$  should extend F and preserve colimits, we are forced to define it on objects  $A: \mathcal{C}^{op} \to Set$  (using the notation of 0.14 applied to  $\mathcal{T} = \mathcal{C}^{op}$ ) by

$$F^*A = \operatorname{colim}_{ElA} (F \cdot \Phi_A).$$

The definition on morphisms (that is, natural transformations)  $h: A_1 \to A_2$ is also obvious: h induces a functor  $Elh: ElA_1 \to ElA_2$  which to every element (X, x) of  $A_1$  assigns the corresponding element  $(X, h_X(x))$  of  $A_2$ . By the universal property of colimits, Elh induces a morphism

$$h': colim (F \cdot \Phi_{A_1}) \rightarrow colim (F \cdot \Phi_{A_2})$$

and we are forced to define  $F^*h = h'$ .

The above rule  $A \mapsto \operatorname{colim} (F \cdot \Phi_A)$  defines a functor  $F^* \colon \operatorname{Set}^{\mathcal{C}^{op}} \to \mathcal{B}$  which fulfils  $F^* \cdot Y_{\mathcal{C}^{op}} \simeq F$  because, for  $A = Y_{\mathcal{C}^{op}}(X) = \mathcal{C}(-, X)$ , a colimit of  $F \cdot \Phi_A = \mathcal{B}(-, FX)$  is FX. It remains to prove that  $F^*$  preserves colimits: for this we prove that  $F^*$  has the following right adjoint

$$R: \mathcal{B} \to Set^{\mathcal{C}^{op}}, \ RB = \mathcal{B}(F-, B).$$

We prove the adjunction  $F^* \dashv R$  by verifying that there is a bijection

$$\mathcal{B}(F^*A, B) \simeq Set^{\mathcal{C}^{op}}(A, RB)$$

natural in  $A: \mathcal{C}^{op} \to Set$  and  $B \in \mathcal{B}$ . In fact, the definition of  $F^*$  makes it clear that the left-hand side consists of precisely all cocones of the diagram  $F \cdot \Phi_A$  with codomain B in  $\mathcal{B}$ :

$$\mathcal{B}(F^*A, B) = \mathcal{B}(colim(F \cdot \Phi_A), B) \simeq lim \mathcal{B}(F(\Phi_A(X, x)), B)$$

February 1, 2010

40

The same is true about the right-hand side: recall that  $A = colim(Y_{\mathcal{C}^{op}} \cdot \Phi_A)$ (0.14), thus a natural transformation from A to RB is a cocone of the diagram  $Y_{\mathcal{C}^{op}} \cdot \Phi_A$  with codomain RB:

$$Set^{\mathcal{C}^{op}}(A, RB) = Set^{\mathcal{C}^{op}}(colim(Y_{\mathcal{C}^{op}} \cdot \Phi_A), RB) \simeq lim Set^{\mathcal{C}^{op}}(Y_{\mathcal{C}^{op}}(\Phi_A(X, x)), RB)$$

Yoneda Lemma tells us that morphisms from the objects  $Y_{\mathcal{C}^{op}}(X)$  of that diagram to  $RB = \mathcal{B}(F-, B)$  are precisely the members of the set  $\mathcal{B}(FX, B)$ :

$$Set^{\mathcal{C}^{op}}(Y_{\mathcal{C}^{op}}(X), RB) \simeq \mathcal{B}(FX, B).$$

In this sense, morphisms from A to RB in  $Set^{C^{op}}$  encode precisely the cocones of  $F \cdot \Phi_A$  with codomain B.

### 4.11 Remark.

1. Although the triangle in Definition 4.9 commutes up to natural isomorphism only, in 4.10 it is actually always possible to choose  $F^*$  so that the (strict) equality

$$F = F^* \cdot Y_{\mathcal{C}}$$

holds. This is easily seen from the above proof since if the algebra A has the form  $A = Y_{\mathcal{C}^{op}}(X)$  a colimit of  $F \cdot \Phi_A$  can be chosen to be FX.

2. Let  $Colim(Set^{\mathcal{C}^{op}}, \mathcal{B})$  be the full subcategory of  $\mathcal{B}^{\mathcal{C}}$  of all functors preserving colimits. Then composition with  $Y_{\mathcal{C}^{op}}$  defines a functor

$$-\cdot Y_{\mathcal{C}^{op}}\colon Colim(Set^{\mathcal{C}^{op}},\mathcal{B})\to \mathcal{B}^{\mathcal{C}}.$$

The above universal property tells us that this functor is an equivalence. (It is, however, not an isomorphism of categories even assuming the choice in 1. above.)

### 4.12 Example.

1. A famous classical example is the free completion under filtered colimits denoted by

$$E_{Ind}: \mathcal{C} \to Ind\mathcal{C}$$
.

For a small category C, IndC can be described as the category of all filtered colimits of representable functors in  $Set^{C^{op}}$ , and the functor  $E_{Ind}$  is the codomain restriction of the Yoneda embedding.

2. One can proceed analogously with sifted colimits: we denote the free completion under sifted colimits by

$$E_{Sind}: \mathcal{C} \to Sind\mathcal{C}$$
.

For a small category C, SindC can be described as the category of all sifted colimits of representable functors in  $Set^{C^{op}}$ , and  $E_{Sind}$  is the codomain restriction of the Yoneda embedding. We are not going to prove these results in full generality here (the interested reader can find them in [9]). We only prove 2. under the assumption that C has finite coproducts, and we sketch the proof of 1. under the assumption that C has finite colimits.

**4.13 Theorem.** For every algebraic theory  $\mathcal{T}$  the Yoneda embedding

$$Y_{\mathcal{T}}: \mathcal{T}^{op} \to Alg \mathcal{T}$$

is a free completion of  $\mathcal{T}^{op}$  under sifted colimits. In other words,

$$Alg \mathcal{T} = Sind(\mathcal{T}^{op}).$$

Analogously to 4.11 we have, for every functor  $F: \mathcal{T}^{op} \to \mathcal{B}$ , a choice of a sifted colimit preserving functor  $F^*: Alg\mathcal{T} \to \mathcal{B}$  satisfying  $F = F^* \cdot Y_{\mathcal{T}}$ .

**Proof.** This is analogous to the proof of 4.10 with  $\mathcal{T} = \mathcal{C}^{op}$ . Given a functor  $F: \mathcal{T}^{op} \to \mathcal{B}$  where  $\mathcal{B}$  has sifted colimits, we prove that there exists an essentially unique functor

$$F^* \colon Alg \mathcal{T} \to \mathcal{B}$$

preserving sifted colimits and such that  $F \simeq F^* \cdot Y_T$ . By 0.14 we are forced to define  $F^*$  on objects  $A = colim(Y_T \cdot \Phi_A)$  by

$$F^*A = \operatorname{colim}_{ElA} (F \cdot \Phi_A).$$

This definition makes sense because, by 4.2, ElA is sifted. As in 4.10 all that needs to be proved is that the resulting functor  $F^*$  preserves sifted colimits. In the present situation  $F^*$  does not have a right adjoint. Nevertheless, since the inclusion  $I: AlgT \to Set^T$  preserves sifted colimits (2.5), we still have, for  $RB = \mathcal{B}(F-, B)$ , a bijection

$$\mathcal{B}(F^*A, B) \simeq Set^{\ T}(IA, RB)$$

natural in  $A: \mathcal{C}^{op} \to Set$  and  $B \in \mathcal{B}$ . The argument is analogous to 4.10: both sides represent cocones of the (sifted) diagram  $F \cdot \Phi_A$  with codomain B. From the above natural bijection one deduces that  $F^*$  preserves sifted colimits: for every fixed B the functor  $A \mapsto \mathcal{B}(F^*A, B)$  preserves sifted colimits, now use 0.12.

**4.14 Corollary.** A category  $\mathcal{A}$  is algebraic if and only if it is a free completion of a small category with finite coproducts under sifted colimits.

**4.15 Remark.** Let  $\mathcal{T}$  be an algebraic theory. If  $\mathcal{B}$  is cocomplete and the functor  $F: \mathcal{T}^{op} \to \mathcal{B}$  preserves finite coproducts, then its extension

$$F^* \colon Alg \mathcal{T} \to \mathcal{B}$$

preserving sifted colimits has a right adjoint. In fact, since F preserves finite coproducts, the functor  $B \mapsto \mathcal{B}(F-, B)$  factorizes through  $Alg \mathcal{T}$  and the resulting functor

$$R: \mathcal{B} \to Alg \mathcal{T}, \ B \mapsto \mathcal{B}(F-, B)$$

is a right adjoint to  $F^*$ .

February 1, 2010 42

**4.16 Remark.** Let  $\mathcal{T}$  be a finitely complete small category and  $Lex\mathcal{T}$  denote the full subcategory of  $Set^{\mathcal{T}}$  of finite limits preserving functors.

- 1.  $Y_{\mathcal{T}}: \mathcal{T}^{op} \to Lex\mathcal{T}$  preserves finite colimits.
- 2. The embedding  $Lex \mathcal{T} \to Set^{\mathcal{T}}$  preserves limits and filtered colimits.
- 3.  $Lex \mathcal{T}$  is cocomplete.

The proofs of 1. and 2. are easy modifications of 1.13, 1.21 and 2.5. Using 4.3, the proof of 3. is analogous to that of 4.5.

**4.17 Theorem.** For every finitely complete small category  $\mathcal{T}$  the Yoneda embedding

$$Y_{\mathcal{T}} \colon \mathcal{T}^{op} \to Lex\mathcal{T}$$

is a free completion of  $\mathcal{T}^{op}$  under filtered colimits. In other words,

$$Lex \mathcal{T} = Ind(\mathcal{T}^{op}).$$

**Proof.** A functor  $A: \mathcal{T} \to Set$  preserves finite limits iff ElA is filtered (4.3). Moreover, the embedding  $Lex\mathcal{T} \to Set^{\mathcal{T}}$  preserves filtered colimits (4.16). The rest of the proof is a trivial modification of the proof of 4.13, just replace "sifted" with "filtered" everywhere.

**4.18 Remark.** Let  $\mathcal{T}$  be a finitely complete small category. Analogously to 4.15, if  $\mathcal{B}$  is cocomplete and the functor  $F: \mathcal{T}^{op} \to \mathcal{B}$  preserves finite colimits, then its extension  $F^*: Lex\mathcal{T} \to \mathcal{B}$  preserving filtered colimits has a right adjoint.

### Historical Remarks for Chapter 4

Free colimit completions (see Theorem 4.10) were probably first described by F. Ulmer [91], see also [45]. The completion *Ind* was introduced by A.Grothendieck and J. L.Verdier in [15], but it is also contained in [45]. The completion *Sind* was introduced in [9], together with its relation to algebraic categories. But a general completion under a class of colimits is already treated in [45]. Later, these completions were studied by a number of authors, see e.g. the results and the references in [56] and [3].

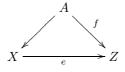

### CHAPTER 4. ALGEBRAIC CATEGORIES AS FREE COMPLETIONS

### Chapter 5

# **Properties of algebras**

In classical algebra a number of abstract properties of algebras play a central role. For example, finite presentability: this means that the algebra can be presented (up to isomorphism) by finitely many generators and equations. However, this is a definitely "categorical" property because it is satisfied by precisely those algebras whose hom-functor preserves filtered colimits, see Chapter 11. Another important concept is that of regular projective algebra (see definition below). The combination of the above properties is called perfect presentability, and we prove that perfectly presentable algebras are precisely those algebras whose hom-functor preserves sifted colimits.

**5.1 Definition.** An object A of a category  $\mathcal{A}$  is called *regular projective* if its hom-functor  $\mathcal{A}(A, -): \mathcal{A} \to Set$  preserves regular epimorphisms. That is, for every regular epimorphism  $e: X \to Z$  and every morphism  $f: A \to Z$  there exists a commutative triangle

#### 5.2 Example.

- 1. In Set all objects are regular projective.
- 2. We will see in 11.26 that every free algebra is regular projective.
- 3. Every regular projective abelian group is free: express A as a regular quotient  $e: X \to A$  of a free abelian group X and apply the previous definition to  $f = id_A$ . This shows that A is isomorphic to a subgroup of a free abelian group and, therefore, it is free. The same argument holds for regular projective groups and for regular projective Lie algebras.
- 4. Every finite boolean algebra (not only the free ones) is regular projective, being a retract of a free boolean algebra.

- 5. A graph G is regular projective in Graph (see 1.11) iff its edges are pairwise disjoint. That is, G is a coproduct of vertices and edges.
- **5.3 Definition.** Let  $\mathcal{A}$  be a category. An object A of  $\mathcal{A}$  is:
  - 1. *finitely presentable* if the hom-functor  $\mathcal{A}(A, -) : \mathcal{A} \to Set$  preserves filtered colimits;
  - 2. perfectly presentable if the hom-functor  $\mathcal{A}(A, -): \mathcal{A} \to Set$  preserves sifted colimits.

**5.4 Remark.** Any perfectly presentable object is finitely presentable (because filtered colimits are sifted) and, assuming the existence of kernel pairs, regular projective (because regular epimorphisms are coequalizers of reflexive pairs). We will show in 5.16 that in an algebraic category also the converse implication holds: perfectly presentable objects are precisely the finitely presentable regular projectives. In fact, the converse implication holds in any cocomplete exact category, see 18.3.

**5.5 Example.** Let  $\mathcal{T}$  be a small category.

- 1. In  $Set^{\mathcal{T}}$  the representable functors are perfectly presentable, in fact, they have a stronger property: their hom-functors preserve *all* colimits. This follows from Yoneda Lemma and the fact that in  $Set^{\mathcal{T}}$  colimits are formed objectwise.
- 2. If  $\mathcal{T}$  is an algebraic theory, representable functors are perfectly presentable objects in  $Alg \mathcal{T}$ . This follows from 1. and the fact that  $Alg \mathcal{T}$  is closed in  $Set^{\mathcal{T}}$  under sifted colimits, see 2.5.
- 3. Analogously, if  $\mathcal{T}$  has finite limits, then representable functors are finitely presentable objects in  $Lex\mathcal{T}$ . This follows from 1. and the fact that  $Lex\mathcal{T}$  is closed in  $Set^{\mathcal{T}}$  under filtered colimits, see 4.16.

### 5.6 Example.

- 1. Every finite set is perfectly presentable in Set.
- 2. An abelian group A is finitely presentable in the above sense in the category Ab iff it is finitely presentable in the usual algebraic sense: that is, A can be presented by finitely many generators and finitely many equations. This is easily seen from the fact that every abelian group is a filtered colimit of abelian groups that are finitely presentable (in the algebraic sense).

An abelian group is perfectly presentable iff it is free on finitely many generators.

3. In a poset considered as a category the finitely (or perfectly) presentable objects are precisely the *compact* elements x, i.e., such that for every directed join  $y = \bigvee_{i \in I} y_i$ , from  $x \leq y$  it follows that  $x \leq y_i$  for some  $i \in I$ .

### CHAPTER 5. PROPERTIES OF ALGEBRAS

4. A graph is finitely presentable in *Graph* iff it has finitely many vertices and finitely many edges. In fact, it is easy to see that for each such a graph G the hom-functor Graph(G, -) preserves filtered colimits. Conversely, if G is finitely presentable, use the fact that G is a filtered colimit of all of its subgraphs on finitely many vertices and finitely many edges.

A graph is perfectly presentable iff it has finitely many vertices and finitely many pairwise disjoint edges.

**5.7 Remark.** We will see in Chapter 11 that the situation described for Ab in the above example is a special case of the general fact that:

- 1. finite presentability has in algebraic categories the usual algebraic meaning (finitely presentable objects are precisely those which can be, in the classical sense, presented by finitely many generators and finitely many equations),
- 2. every free algebra is regular projective,
- 3. perfectly presentable algebras are just the retracts of the free algebras on finitely many generators.

**5.8 Remark.** As pointed out in 5.5, in categories Set<sup>C</sup> the representable objects have the property that their hom-functors preserve all colimits. We call such objects absolutely presentable. In algebraic categories, absolutely presentable objects are typically rare. For example no abelian group A is absolutely presentable: for the initial object 1, the object Ab(A, 1) is never initial in Set. However, the categories  $Set^{C}$  are an exception: every object is a colimit of absolutely presentable objects.

**5.9 Lemma.** If an object is regular projective (or finitely presentable or perfectly presentable) then every retract has that property too.

**Proof.** If  $f: B \to A$  and  $g: A \to B$  are such that  $g \cdot f = id_B$ , then the natural transformations

$$\alpha = \mathcal{A}(g, -) \colon G = \mathcal{A}(B, -) \to F = \mathcal{A}(A, -) \text{ and } \beta = \mathcal{A}(f, -) \colon F \to G$$

fulfil  $\beta \cdot \alpha = G$ . Therefore,

$$F \xrightarrow[F]{\alpha \cdot \beta} F \xrightarrow[F]{\beta} G$$

is a coequalizer. By interchange of colimits, G preserves every colimit preserved by F.

**5.10 Remark.** Absolutely presentable objects in  $Set^{\mathcal{C}}$  are precisely the retracts of the representable functors.

### 5.11 Lemma.

- 1. Perfectly presentable objects are closed under finite coproducts.
- 2. Finitely presentable objects are closed under finite colimits.

**Proof.** Let us prove the first statement (the proof of the second one is similar). Consider a finite family  $(A_i)_{i \in I}$  of perfectly presentable objects. Since  $\mathcal{A}(\coprod_I A_i, -) \simeq \prod_I \mathcal{A}(A_i, -)$ , the claim follows from the obvious fact that a finite product of functors  $\mathcal{A} \to Set$  preserving sifted colimits also preserves them.

**5.12 Corollary.** Every object of an algebraic category is

1. a sifted colimit of perfectly presentable algebras

and

2. a filtered colimit of finitely presentable algebras.

In fact, 1. follows from 4.2 and 5.3, and 2. follows from 4.2, 2.21 and 5.11.

5.13 Lemma. Regular projective objects are closed under coproducts.

**Proof.** Let  $(A_i)_{i \in I}$  be a family of regular projective objects and let  $e: X \to Z$  be a regular epimorphism. The claim follows from the formula  $\mathcal{A}(\coprod_I A_i, e) \simeq \prod_I \mathcal{A}(A_i, e)$  and the fact that in *Set* regular epimorphisms are stable under products (3.21).

**5.14 Corollary.** In every category Alg T:

- 1. The perfectly presentable objects are precisely the retracts of representable algebras.
- 2. The regular projective objects are precisely the retracts of coproducts of representable algebras.

**Proof.** 1: Following 5.5 and 5.9, a retract of a representable algebra is perfectly presentable. Conversely, following 4.2, we can express every perfectly presentable algebra A as a sifted colimit of representable algebras. Since  $Alg \mathcal{T}(A, -)$  preserves this colimit, it follows that  $id_A$  factorizes through some of the colimit morphism  $e: Y_{\mathcal{T}}(t) \to A$ . Thus e is a split epimorphism and A is a retract of  $Y_{\mathcal{T}}(t)$ .

2: Following 5.5, 5.9 and 5.13, a retract of a coproduct of representable algebras is regular projective. Conversely, following 4.2, we can express every algebra A as a colimit of representable algebras. Since  $Alg \mathcal{T}$  is cocomplete, this implies, by 0.7, that A is a regular quotient of a coproduct of representable algebras

$$e \colon \prod_{i \in I} \mathcal{T}(t_i, -) \to A.$$

$$[5.1]$$

Therefore, if A is regular projective, it is a retract of  $\coprod_{i \in I} \mathcal{T}(t_i, -)$ .

February 1, 2010

48

### CHAPTER 5. PROPERTIES OF ALGEBRAS

**5.15 Corollary.** Every algebraic category has enough regular projective objects, *i.e.*, every algebra is a regular quotient of a regular projective algebra.

In fact, use [5.1] from the above proof: e is a regular epimorphism and, following 5.5 and 5.13,  $\prod_{i \in I} \mathcal{T}(t_i, -)$  is a regular projective object.

**5.16 Corollary.** In an algebraic category, an algebra is perfectly presentable if and only if it is finitely presentable and regular projective.

**Proof.** One implication holds in any category, see 5.4. Conversely, if P is a regular projective object in AlgT, due to 5.14.2 P is a retract of a coproduct of representable algebras. Since every coproduct is a filtered colimit of its finite subcoproducts (2.21), if P is also finitely presentable, then it is a retract of a finite coproduct of representable algebras. Following 5.5, 5.9 and 5.11.1, P is perfectly presentable.

**5.17 Proposition.** In every algebraic category the finitely presentable algebras are precisely the coequalizers of reflexive pairs of homomorphisms between representable algebras.

**Proof.** One implication is obvious: representable algebras are finitely presentable (5.5), and finitely presentable objects are closed under finite colimits (5.11).

Conversely, let A be a finitely presentable algebra. Following 4.2, A is a (sifted) colimit of representable algebras. Thus, A is a filtered colimit of finite colimits of representable algebras, see 2.21. From 1.13 and 0.7 we deduce that every finite colimit of representable algebras is a reflexive coequalizer of a parallel pair between two representable algebras. Since A is finitely presentable, it is a retract of one of the above coequalizers:

$$Y_{\mathcal{T}}(t_1) \xrightarrow{h}_{k} Y_{\mathcal{T}}(t_2) \xrightarrow{e} Q \xrightarrow{s}_{u} A$$

Here e is a coequalizer of h and k, and  $s \cdot u = id_A$ . Since  $Y_T(t_2)$  is regular projective (see 5.4 and 5.5) and e is a regular epimorphism, there exists a homomorphism  $g: Y_T(t_2) \to Y_T(t_2)$  such that  $e \cdot g = u \cdot s \cdot e$ . Let us observe that the morphism  $s \cdot e$  is a joint coequalizer of h, k and  $g \cdot h$ :

$$Y_{\mathcal{T}}(t_1) \xrightarrow{h} Y_{\mathcal{T}}(t_2) \xrightarrow{s \cdot e} A$$

In fact,  $s \cdot e \cdot k = s \cdot e \cdot h = s \cdot u \cdot s \cdot e \cdot h = s \cdot e \cdot g \cdot h$ . Assume that a morphism  $f \colon Y_T(t_2) \to X$  coequalizes h, k, and  $g \cdot h$ . Then there exists a unique homomorphism  $v \colon Q \to X$  with  $v \cdot e = f$ . Hence  $f \cdot h = f \cdot g \cdot h = v \cdot e \cdot g \cdot h = v \cdot u \cdot s \cdot e \cdot h$ . Since h is an epimorphism (because the pair h, k is reflexive), we get  $f = v \cdot u \cdot s \cdot e$ . Now, from 0.7 we conclude that A is a reflexive coequalizer of a pair of homomorphisms between finite coproducts of representable algebras. By 1.13, we get the claim.

**5.18 Remark.** Beside finite presentability, an important concept in general algebra is finite generation: an algebra A is finitely generated if it has a finite subset not contained in any proper subalgebra. (Or, equivalently, A is a regular quotient of a free algebra on finitely many generators.) This concept also has a categorical formulation. For this we need to introduce the following

**5.19 Definition.** A directed union is a filtered colimit of subobjects. That is, given a filtered diagram  $D: \mathcal{D} \to \mathcal{A}$  where D maps every morphism to a monomorphism, then  $\operatorname{colim} D$  is called the directed union.

**5.20 Remark.** In *Set* directed unions have colimit cocones formed by monomorphisms. Thus, the same holds in  $Set^{\mathcal{T}}$ . Since  $Alg\mathcal{T}$  is closed under filtered colimits in  $Set^{\mathcal{T}}$ , this is also true in  $Alg\mathcal{T}$ .

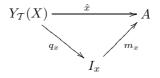

**5.21 Definition.** Let  $\mathcal{A}$  be a category. An object A of  $\mathcal{A}$  is *finitely generated* if the hom-functor  $\mathcal{A}(A, -): \mathcal{A} \to Set$  preserves directed unions.

**5.22 Proposition.** In every algebraic category the finitely generated algebras are precisely the regular quotients of representable algebras.

**Proof.** 1. Let A be finitely generated. Recall from 4.2 that A is the sifted colimit of

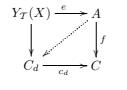

$$ElA \xrightarrow{\Phi_A} \mathcal{T}^{op} \xrightarrow{Y_T} AlgT$$

Let (X, x) be an object of ElA and consider the regular factorization of the colimit morphism  $\hat{x}$ :

These objects  $I_x$  and the connecting monomorphisms between them one gets from the morphisms of ElA (via diagonal fill-in, see 0.16) form a filtered diagram of monomorphisms. Indeed, given two elements (X, x) and (Z, z) of A, for the element  $(X \times Z, (x, z))$  we see that  $m_x$  and  $m_z$  both factorize through  $m_{(x,z)}$ . It is clear that  $A = colim I_x$ , and since A is finitely generated,  $\mathcal{A}(A, -)$ preserves this colimit. Thus there exists  $(X, x) \in ElA$  and  $f: A \to I_x$  such that  $id_A = m_x \cdot f$ . Therefore  $m_x$ , being a monomorphism and a split epimorphism, is an isomorphism. This implies that  $\hat{x}: Y_T(X) \to A$  is a regular epimorphism. 2. For every regular epimorphism  $e: Y_T(X) \to A$  in  $Alg\mathcal{T}$  we prove that A is finitely generated. Given a filtered diagram  $D: \mathcal{D} \to Alg\mathcal{T}$  of subobjects with colimit cocone  $c_d: Dd \to C$  ( $d \in obj\mathcal{D}$ ), since each  $c_d$  is a monomorphism (5.20) it is sufficient to prove that every morphism  $f: A \to C$  factorizes through some  $c_d$ . In fact, since  $Y_T(X)$  is finitely presentable, the morphism  $f \cdot e: Y_T(X) \to C$ 

factorizes through some  $c_d$  – and then we just use the diagonal fill-in:

**5.23 Example.** In the category  $\mathbb{N}/Set$  of sets with countably many constants the finitely generated objects are those that have, beside the constants, only finitely many elements. Whereas the finitely presentable objects have, moreover, the property that only finitely many pairs of distinct natural numbers label the same constant. (Thus for example the terminal object is finitely generated but not finitely presentable.) Finally, the absolutely presentable objects are those finitely generated objects where the constants are pairwise distinct.

### Historical Remarks for Chapter 5

The lecture notes [45] by P. Gabriel and F. Ulmer is the source of the concept of a finitely presentable object. In [9] perfectly presentable objects were introduced under the name of strongly finitely presentable. In algebraic categories, they coincide with objects "projectif-de-type-fini" of Y. Diers [38] and with the finitely presentable effective projectives of M. C. Pedicchio and R. J. Wood [79].

The term "perfectly presentable" was suggested by A. Joyal (see [55]), his motivation comes from perfect complexes as explained in 6.11 below.

51

February 1, 2010

### CHAPTER 5. PROPERTIES OF ALGEBRAS

### Chapter 6

# A characterization of algebraic categories

We have already characterized algebraic categories as free completions (see 4.14). The aim of this chapter is to characterize them as those cocomplete categories which have a strong generator formed by perfectly presentable objects. From that we derive several stability results about algebraic categories: if  $\mathcal{A}$  is algebraic, then all slice categories  $\mathcal{A} \downarrow \mathcal{A}$  and all functor categories  $\mathcal{A}^{\mathcal{D}}$  are algebraic, and so are the reflective subcategories closed under sifted colimits.

### 6.1 Definition.

- 1. A set of objects  $\mathcal{G}$  in a category  $\mathcal{A}$  is called a *generator* if two morphisms  $x, y: A \rightrightarrows B$  are equal whenever  $x \cdot g = y \cdot g$  for every morphisms  $g: G \to A$  with domain G in  $\mathcal{G}$ .
- 2. A generator  $\mathcal{G}$  is called *strong* if a monomorphism  $m: A \to B$  is an isomorphism whenever every morphism  $g: G \to B$  with domain G in  $\mathcal{G}$  factorizes through m.

**6.2 Remark.** Here is an equivalent way to express the notions of generator and strong generator. Consider the functor

 $\mathcal{A} \to Set^{\mathcal{G}}, \quad A \mapsto \langle \mathcal{A}(G,A) \rangle_{G \in \mathcal{G}}.$ 

- 1.  $\mathcal{G}$  is a generator iff the above functor is faithful.
- 2.  $\mathcal{G}$  is a strong generator iff the above functor is faithful and conservative (see 0.2).

The following proposition suggests that "strong" generator should more properly be called "extremal", the present terminology has just historical reasons.

**6.3 Proposition.** In a category  $\mathcal{A}$  with coproducts a set of objects  $\mathcal{G}$  is

- a generator if and only if every object of A is a quotient of a coproduct of objects from G,
- 2. a strong generator if and only if every object of  $\mathcal{A}$  is an extremal quotient of a coproduct of objects from  $\mathcal{G}$ .

Explicitly:  $\mathcal{G}$  is a (strong) generator iff for every object A in  $\mathcal{A}$ , an (extremal) epimorphism

$$e \colon \coprod_{i \in I} G_i \to A$$

exists with all  $G_i$  in  $\mathcal{G}$ . We will see in the proof that this is equivalent to saying that the *canonical morphism* 

$$e_A \colon \coprod_{(G,g) \in \mathcal{G} \downarrow A} G \to A$$

whose (G, g)-component is g, is an (extremal) epimorphism.

**Proof.** 1. If  $\mathcal{G}$  is a generator, then the canonical morphism  $e_A$  is obviously an epimorphism. Conversely, if  $e: \coprod_{i \in I} G_i \to A$  is an epimorphism, then given distinct morphisms  $x, y: A \rightrightarrows B$ , some component  $e_i: G_i \to A$  fulfils  $x \cdot e_i \neq y \cdot e_i$ . 2. Let  $\mathcal{G}$  be a strong generator. If  $e_A$  factorizes through a monomorphism m, then all of its components  $g: G \to A$  factorize through m. Since  $\mathcal{G}$  is a strong generator, this implies that m is an isomorphism. Conversely, let  $e: \coprod_{i \in I} G_i \to A$  be an extremal epimorphism, and consider a monomorphism  $m: B \to A$ . If every morphism  $g: G \to A$  (with G varying in  $\mathcal{G}$ ) factorizes through m, then efactorizes through m, so that m is an isomorphism.

**6.4 Corollary.** If  $\mathcal{A}$  has colimits and every object of  $\mathcal{A}$  is a colimit of objects from a set  $\mathcal{G}$ , then  $\mathcal{G}$  is a strong generator.

In fact, this follows from 0.7 and 6.3, because any regular epimorphism is extremal.

### 6.5 Example.

- 1. Every nonempty set forms a (singleton) strong generator in Set.
- 2. The group of integers forms a strong generator in Ab.
- 3. In the category of posets and order-preserving functions the terminal (oneelement) poset forms a generator – but this generator is not strong. In contrast, the two-element chain is a strong generator.

### 6.6 Example.

1. Let C be a small category. Then  $Set^{C}$  has a strong generator formed by all representable functors. This follows from 0.14 and 6.4.

2. Analogously, for an algebraic theory  $\mathcal{T}$  the category  $Alg\mathcal{T}$  has a strong generator formed by all representable algebras: see 6.4 and 4.2.

**6.7 Lemma.** Let  $\mathcal{A}$  be a cocomplete category with a set of perfectly presentable objects such that every object of  $\mathcal{A}$  is a sifted colimit of objects of that set. Then  $\mathcal{A}$  has, up to isomorphism, only a set of perfectly presentable objects.

**Proof.** Express an object A of  $\mathcal{A}$  as a sifted colimit of objects from the given set  $\mathcal{G}$ . If A is perfectly presentable, then it is a retract of an object from  $\mathcal{G}$ . Clearly, each retract of an object B gives rise to an idempotent morphism  $e: B \to B, e \cdot e = e$ . Moreover, if two retracts give rise to the same idempotent, then they are isomorphic. Since each object from  $\mathcal{A}$  has only a set of retracts our claim is proved.

**6.8 Remark.** A result analogous to 6.7 holds for finitely presentable objects and filtered colimits. The proof is the same.

**6.9 Theorem.** (Characterization of algebraic categories) The following conditions on a category A are equivalent:

- 1.  $\mathcal{A}$  is algebraic;
- 2. A is cocomplete and has a set  $\mathcal{G}$  of perfectly presentable objects such that every object of  $\mathcal{A}$  is a sifted colimit of objects of  $\mathcal{G}$ ;
- 3. A is cocomplete and has a strong generator consisting of perfectly presentable objects.

Moreover if the strong generator  $\mathcal{G}$  in 3. is closed under finite coproducts, then the dual of  $\mathcal{G}$  (seen as a full subcategory) is an algebraic theory of  $\mathcal{A}$ .

**Proof.**  $1 \Rightarrow 2$ : Let  $\mathcal{T}$  be an algebraic theory. Then  $Alg\mathcal{T}$  is cocomplete (4.5), the representable algebras form a set of perfectly presentable objects (5.5), and every algebra is a sifted colimit of representable algebras (4.2).

 $2 \Rightarrow 3$ : Consider the family  $\mathcal{A}_{pp}$  of all perfectly presentable objects of  $\mathcal{A}$ . By 6.7,  $\mathcal{A}_{pp}$  is essentially a set. By 6.4, it is a strong generator.

 $3 \Rightarrow 1$ : Let  $\mathcal{G}$  be a strong generator consisting of perfectly presentable objects. Since perfectly presentable objects are closed under finite coproducts (5.11), we can assume without loss of generality that  $\mathcal{G}$  is closed under finite coproducts (if this is not the case, we can replace  $\mathcal{G}$  by its closure in  $\mathcal{A}$  under finite coproducts, which still is a strong generator). We are going to prove that  $\mathcal{A}$  is equivalent to  $Alq(\mathcal{G}^{op})$ , where  $\mathcal{G}$  is seen as a full subcategory of  $\mathcal{A}$ .

(a) We prove first that  $\mathcal{G}$  is *dense*, i.e., for every object K of  $\mathcal{A}$  the canonical diagram of all morphisms from  $\mathcal{G}$ 

$$D_K \colon \mathcal{G} \downarrow K \to \mathcal{A} , \ (g \colon G \to K) \mapsto G$$

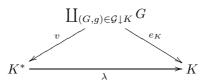

has K as colimit, with  $(g: G \to K)$  as colimit cocone. To prove this, form a colimit cocone of  $D_K$ :

$$(c_g: G \to K^*)$$
 for all  $g: G \to K$  in  $\mathcal{G} \downarrow K$ .

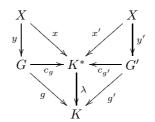

We have to prove that the unique factorizing morphism  $\lambda \colon K^* \to K$  with  $\lambda \cdot c_g = g$  for all g in  $\mathcal{G} \downarrow K$  is an isomorphism. Consider the coproduct

with coproduct injections  $\rho_g \colon G \to \coprod_{(G,g) \in \mathcal{G} \downarrow K} G$ . We have a commutative triangle

where  $e_K$  is the canonical morphism 6.3 and v is defined by  $v \cdot \rho_g = c_g$  for all  $(G,g) \in \mathcal{G} \downarrow K$ . Since  $e_K$  is an extremal epimorphism (see 6.3), then  $\lambda$ is an extremal epimorphism. It remains to prove that  $\lambda$  is a monomorphism. Consider two morphisms  $x, x' \colon X \rightrightarrows K^*$  such that  $\lambda \cdot x = \lambda \cdot x'$ , and let us prove that x = x'. While  $\mathcal{G}$  is a (strong) generator, we can assume without loss of generality that X is in  $\mathcal{G}$ . Since  $\mathcal{G} \downarrow K$  is sifted (in fact, it has finite coproducts, because  $\mathcal{G}$  has, see 2.16) and X is perfectly presentable, both x and x' factorize through some colimit morphism: that is, for some (G,g) and (G',g') in  $\mathcal{G} \downarrow K$ we have a commutative diagram

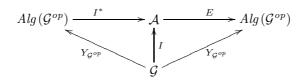

Since  $c_{\lambda \cdot x} = c_g \cdot y = x$  and analogoulary  $c_{\lambda \cdot x'} = x'$ , we get  $x = c_{\lambda \cdot x} = c_{\lambda \cdot x'} = x'$ . (b) It follows from (a) that the functor

$$E: \mathcal{A} \to Alg(\mathcal{G}^{op}), \quad K \mapsto \mathcal{A}(-, K)$$

is full and faithful. Indeed, given a homomorphism  $\alpha: \mathcal{A}(-, K) \to \mathcal{A}(-, L)$ , for every  $g: G \to K$  in  $\mathcal{G} \downarrow K$  we have a morphism  $\alpha_G(g): G \to L$ . Those morphisms form a cocone on  $\mathcal{G} \downarrow K$ , so that there exists a unique morphism  $\hat{\alpha}: K \to L$  such that  $\hat{\alpha} \cdot g = \alpha_G(g)$  for all g in  $\mathcal{G} \downarrow K$ . It is easy to check that  $E\hat{\alpha} = \alpha$  and that  $\widehat{Ef} = f$  for all  $f: K \to L$  in  $\mathcal{A}$ . It remains to prove that E is essentially surjective on objects.

(c) Let us prove first that E preserves sifted colimits. Consider a sifted diagram  $D: \mathcal{D} \to \mathcal{A}$  with colimit  $(h_d: Dd \to H)$ . For every object G in  $\mathcal{G}$  a colimit of  $\mathcal{A}(G, -) \cdot D$  in Set is  $\mathcal{A}(G, H)$  with the colimit cocone  $\mathcal{A}(G, Dd) \to \mathcal{A}(G, H)$  given by composition with  $h_d$  (because  $\mathcal{G}$  is formed by perfectly presentable

objects). This implies that  $(Eh_d: E(Dd) \to EH)$  is a colimit of  $E \cdot D$  in  $Alg(\mathcal{G}^{op})$  (sifted colimits are computed objectwise in  $Alg(\mathcal{G}^{op})$ , see 2.5). (d) It follows from (c) that E is essentially surjective on objects. In fact, we have the following diagram, commutative up to natural isomorphism,

where I is the inclusion and  $I^*$  is its extension preserving sifted colimit (4.13). Since  $E \cdot I^* \cdot Y_{\mathcal{G}^{op}} \simeq Y_{\mathcal{G}^{op}}$  and  $E \cdot I^*$  preserves sifted colimits, it follows from 4.13 that  $E \cdot I^*$  is naturally isomorphic to the identity functor. Thus E is essentially surjective on objects.

### 6.10 Example.

- 1. The category *Pos* of posets and order-preserving maps is not algebraic: only the discrete posets are perfectly presentable, and there exists no strong generator formed by discrete posets.
- 2. In the category *Bool* of Boolean algebras consider the free algebras  $\mathcal{PP}n$  on n generators (where  $\mathcal{P}X$  is the algebra of all subsets of a set X). The dual of the category  $\mathcal{PP}n$  ( $n \in \mathbb{N}$ ) is an algebraic theory for *Bool*. In fact,  $\mathcal{PP}n$  are perfectly presentable and form a strong generator closed under finite coproducts.

**6.11 Example.** Let R be a unitary ring. We denote by Ch(R) the category of chain complexes of left R-modules. Its objects are collections  $X = (X_n)_{n \in \mathbb{Z}}$  of left R-modules equipped with a *differential*, that is, a collection of module homomorphisms

$$d = (d_n \colon X_n \to X_{n-1})_{n \in \mathbb{Z}}$$

where  $d_{n-1} \cdot d_n = 0$  for each n. Morphisms  $f: X \to Y$  are *chain maps*, i.e., collections  $(f_n: X_n \to Y_n)_{n \in \mathbb{Z}}$  of module homomorphisms such that  $d_n \cdot f_n = f_{n-1} \cdot d_n$  for all n.

A complex X is *bounded* if there are only finitely many  $n \in \mathbb{N}$  with  $X_n \neq 0$ . Since every complex is a filtered colimit of its truncations, each finitely presentable complex is bounded. Perfectly presentable objects in Ch(R) are precisely the bounded complexes of perfectly presentable left *R*-modules. Since they form a strong generator of Ch(R), the category Ch(R) is algebraic.

**6.12 Notation.** We denote by  $\mathcal{A}_{pp}$  a full subcategory of  $\mathcal{A}$  representing all perfectly presentable objects of  $\mathcal{A}$  up to isomorphism.

**6.13 Corollary.** For every algebraic category  $\mathcal{A}$  the dual of  $\mathcal{A}_{pp}$  is an algebraic theory of  $\mathcal{A}$ : we have an equivalence functor

$$E: \mathcal{A} \to Alg(\mathcal{A}_{pp}^{op}), \quad A \mapsto \mathcal{A}(-, A).$$

In fact,  $\mathcal{A}_{pp}$  is a strong generator closed under finite coproducts.

**6.14 Corollary.** Two algebraic categories  $\mathcal{A}$  and  $\mathcal{B}$  are equivalent if and only if the categories  $\mathcal{A}_{pp}$  and  $\mathcal{B}_{pp}$  are equivalent.

**Proof.** This follows immediately from 6.13 and the fact that equivalence functors preserve perfectly presentable objects.  $\Box$ 

From 1.5 we know that the slice category  $Set \downarrow S$ , equivalent to the category  $Set^{S}$  of S-sorted sets, is algebraic. This is a particular case of a more general fact:

**6.15 Proposition.** Every slice category  $\mathcal{A} \downarrow \mathcal{A}$  of an algebraic category  $\mathcal{A}$  is algebraic.

**Proof.** The category  $\mathcal{A} \downarrow A$  is cocomplete: consider a small category  $\mathcal{D}$  and a functor

 $F: \mathcal{D} \to \mathcal{A} \downarrow \mathcal{A}$ ,  $FD = (F_D, f_D: F_D \to \mathcal{A})$ .

A colimit of F is given by (C, c), where  $(C, \sigma_D : F_D \to C)$  is a colimit of  $\Phi_A \cdot F$ where  $\Phi_A : \mathcal{A} \downarrow A \to \mathcal{A}$  is the forgetful functor, and  $c \cdot \sigma_D = f_D$  for every object D in  $\mathcal{D}$ . This immediately implies that an object (G, g) is perfectly presentable in  $\mathcal{A} \downarrow A$  as soon as G is perfectly presentable in  $\mathcal{A}$ . Let now  $\mathcal{G}$  be a strong generator of  $\mathcal{A}$ . Then the set of objects  $\mathcal{G} \downarrow A = \{(G,g) \mid G \in \mathcal{G}\}$  is a strong generator of  $\mathcal{A} \downarrow A$ . This is so because a morphism  $f : (X, x) \to (Z, z)$  in  $\mathcal{A} \downarrow A$ is a strong epimorphism iff  $f : X \to Z$  is a strong epimorphism in  $\mathcal{A}$ . Following  $6.9, \mathcal{A} \downarrow A$  is algebraic.  $\Box$ 

**6.16 Lemma.** Let the functor  $I: \mathcal{A} \to \mathcal{B}$  have a left adjoint R.

- If I is faithful and conservative and G is a strong generator of B, then R(G) is a strong generator of A.
- 2. If I preserves sifted colimits and X is perfectly presentable in  $\mathcal{B}$ , then RX is perfectly presentable in  $\mathcal{A}$ .

**Proof.** 1:  $R(\mathcal{G})$  is a generator because I is a faithful right adjoint. Next, consider a monomorphism  $a: A \to A'$  in  $\mathcal{A}$  such that every morphism  $RG \to A'$  with  $G \in \mathcal{G}$  factorizes through a. This implies, by adjunction, that every morphism  $G \to IA'$  factorizes through the monomorphism Ia. Since  $\mathcal{G}$  is a strong generator, Ia is an isomorphism, and since I is conservative, a is an isomorphism.

2: Since  $\mathcal{A}(RX, -) \simeq \mathcal{B}(X, I-) = \mathcal{B}(X, -) \cdot I$ , we see that  $\mathcal{A}(RX, -)$  is the composite of two functors preserving sifted colimits.

**6.17 Proposition.** Let  $\mathcal{T}$  be an algebraic theory. Then  $Alg\mathcal{T}$  is a reflective subcategory of Set  $^{\mathcal{T}}$  closed under sifted colimits.

**Proof.** This is a special case of the adjunction  $F^* \dashv \mathcal{B}(F-,-)$  obtained in the proof of 4.10. Indeed, by the Yoneda Lemma, the right adjoint  $Alg\mathcal{T}(Y_{\mathcal{T}}-,-)$  is naturally isomorphic to the full inclusion  $Alg\mathcal{T} \to Set^{\mathcal{T}}$ .

**6.18 Theorem.** A category is algebraic if and only if it is equivalent to a full reflective subcategory of Set<sup>C</sup> closed under sifted colimits, for some small category C.

**Proof.** Let  $\mathcal{T}$  be an algebraic theory. Following 6.17 and 2.5,  $Alg\mathcal{T}$  is a full reflective subcategory closed under sifted colimits of  $Set^{\mathcal{T}}$ .

Conversely, let C be a small category. By 1.14 Set <sup>C</sup> is an algebraic category, so that it fulfils the conditions of 6.9.3. Following 6.16, those conditions are inherited by any full reflective subcategory closed under sifted colimits of Set <sup>C</sup>.

**6.19 Corollary.** For any small category  $\mathcal{D}$ , the functor category  $\mathcal{A}^{\mathcal{D}}$  of an algebraic category  $\mathcal{A}$  is algebraic.

**Proof.** Due to 6.18, there exist a small category C and a full reflection

$$\mathcal{A} \xrightarrow{R} Set^{\mathcal{C}}$$

with the right adjoint  ${\cal I}$  preserving sifted colimits. This induces another full reflection

$$\mathcal{A}^{\mathcal{D}} \xrightarrow[I \to -]{R \cdot -} \left( Set^{\mathcal{C}} \right)^{\mathcal{D}}$$

with  $I \cdot -$  preserving sifted colimits because they are formed objectwise. Since  $(Set^{\mathcal{C}})^{\mathcal{D}} \simeq Set^{\mathcal{C} \times \mathcal{D}}$ , by 6.18  $\mathcal{A}^{\mathcal{D}}$  is algebraic.

**6.20 Remark.** Our Characterization Theorem 6.9 shows a strong parallel between algebraic categories and the following more general concept due to Gabriel and Ulmer [45].

**6.21 Definition.** A category is called *locally finitely presentable* if it is cocomplete and has a set  $\mathcal{G}$  of finitely presentable objects such that every object of  $\mathcal{A}$  is a filtered colimit of objects of  $\mathcal{G}$ .

#### 6.22 Example.

- 1. Following 6.9, all algebraic categories are locally finitely presentable.
- 2. If  $\mathcal{T}$  is a small category with finite limits, then  $Lex\mathcal{T}$ , see 4.16, is a locally finitely presentable category. In fact  $Lex\mathcal{T}$  is cocomplete (4.16), the representable functors form a set of finitely presentable objects (5.5), and every object is a filtered colimit of representable functors (4.3).
- 3. The category *Pos* of posets (which is not algebraic, see 6.10) is locally finitely presentable: the two-element chain which forms a strong generator is finitely presentable. Thus we can apply the following

**6.23 Theorem.** (Characterization of locally finitely presentable categories) The following conditions on a category A are equivalent:

- 1. A is locally finitely presentable;
- 2. A is equivalent to LexT for a small category T with finite limits;
- 3. A is cocomplete and has a strong generator formed by finitely presentable objects.

Moreover if the strong generator  $\mathcal{G}$  in 3. is closed under finite colimits, then  $\mathcal{A}$  is equivalent to  $Lex(\mathcal{G}^{op})$ .

**Proof.** This proof is quite analogous to that of Theorem 6.9: just change  $Alg\mathcal{T}$  to  $Lex\mathcal{T}$  for  $\mathcal{T} = \mathcal{G}^{op}$ , work with finitely presentable objects instead of perfectly presentable ones, and in the proof of  $3 \Rightarrow 2$  use the closure under finite colimits.

**6.24 Corollary.** A category  $\mathcal{A}$  is locally finitely presentable if and only if it is a free completion of a small, finitely cocomplete category under filtered colimits.

In fact, this follows from 4.17 and 6.23.

**6.25 Notation.** We denote by  $\mathcal{A}_{fp}$  a full subcategory of  $\mathcal{A}$  representing all finitely presentable objects of  $\mathcal{A}$  up to isomorphism.

**6.26 Corollary.** Every locally finitely presentable category  $\mathcal{A}$  is equivalent to Lex  $\mathcal{T}$  for some small, finitely complete category  $\mathcal{T}$ . In fact, we have the equivalence functor

$$E: \mathcal{A} \to Lex(\mathcal{A}_{fn}^{op}), \quad A \mapsto \mathcal{A}(-,A).$$

This follows from 6.23 applied to  $\mathcal{G} = \mathcal{A}_{fp}$ .

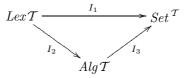

**6.27 Proposition.** Let  $\mathcal{T}$  be a small finitely complete category. Then Lex  $\mathcal{T}$  is a reflective subcategory of Set  $^{\mathcal{T}}$  closed under filtered colimits.

**Proof.** This is a special case of the adjunction  $F^* \dashv \mathcal{B}(F-, -)$  obtained in the proof of 4.10. Indeed, by the Yoneda Lemma, the right adjoint  $Lex \mathcal{T}(Y_T-, -)$  is naturally isomorphic to the full inclusion  $Lex \mathcal{T} \to Set^T$ .

**6.28 Theorem.** A category is locally finitely presentable if and only if it is equivalent to a full reflective subcategory of Set<sup>C</sup> closed under filtered colimits, for some small category C.

**6.29 Corollary.** Let  $\mathcal{T}$  be a small finitely complete category. Then  $Lex\mathcal{T}$  is a full reflective subcategory of  $Alg\mathcal{T}$  closed under filtered colimits.

**Proof.** Consider the full inclusions

February 1, 2010

60

By 6.27,  $I_1$  has a left adjoint, say R. Since  $I_3$  is full and faithful,  $R \cdot I_3$  is left adjoint to  $I_2$ . Finally,  $I_2$  preserves filtered colimits because  $I_1$  preserves them by 6.27 and  $I_3$  reflects them.

In 12.12 we will need the following fact.

**6.30 Corollary.** Let  $\mathcal{A}$  be an algebraic category and  $\mathcal{B}$  a category with sifted colimits. If in  $\mathcal{A}$  every finitely presentable object is regular projective, then a functor  $F: \mathcal{A} \to \mathcal{B}$  preserving filtered colimits preserves also sifted colimits.

**Proof.** Following 6.13 and 6.26

$$Alg(\mathcal{A}_{pp}^{op}) \simeq \mathcal{A} \simeq Lex(\mathcal{A}_{fp}^{op})$$

If moreover finitely presentable objects in  $\mathcal{A}$  are regular projective, then  $\mathcal{A}_{pp} = \mathcal{A}_{fp}$  (5.16). The result now follows from the universal properties stated in 4.13 and 4.17.

**6.31 Example.** Set (and more generally  $Set^S$ ) and the category of vector spaces over a field are examples of algebraic categories where every (finitely presentable) object is regular projective. More generally, in the category of left modules over a semi-simple ring every object is regular projective.

Let us finish this chapter by quoting from [31] another characterization theorem similar to 6.9. Recall that  $Set^{\mathcal{C}}$  is the free completion of  $\mathcal{C}^{op}$  under colimits (4.10); recall also the concept of absolutely presentable object in 5.8.

**6.32 Theorem.** A category is equivalent to a functor category Set<sup>C</sup> for some small category C if and only if it is cocomplete and has a strong generator consisting of absolutely presentable objects.

#### Historical Remarks for Chapter 6

The concept of locally finitely presentable category, due to P. Gabriel and F. Ulmer [45], was an attempt of a categorical approach to categories of finitary structures generalizing Lawvere's algebraic theories. This is the source of 6.23. See [8] and [70] for more recent monographs on locally presentable categories and their generalizations. In [9] the analogy between locally finitely presentable categories and algebraic categories was made explicit.

A characterization of categories of algebras for one-sorted algebraic theories is contained in the thesis of F. W. Lawvere [60]. The characterization 6.9 is taken from [9]. But the equivalence of 1. and 3. was already proved by Y. Diers [38]. A first characterization of categories of *Set*-valued functors is in the thesis of M. Bunge [31] (the first proof was published in [65]). There is a general result covering both 6.9, 6.23 and 6.32 (see [35]).

### CHAPTER 6. A CHARACTERIZATION OF ALGEBRAIC CATEGORIES

## Chapter 7

## From filtered to sifted

The aim of this chapter is to demonstrate that the "equation"

sifted colimits = filtered colimits + reflexive coequalizers

is almost valid – but not quite. What we have in mind are three facts:

- 1. A category C has sifted colimits iff it has filtered colimits and reflexive coequalizers. This holds whenever C has finite coproducts and in general it is false.
- 2. A functor preserves sifted colimits iff it preserves filtered colimits and reflexive coequalizers. This holds whenever the domain category is finitely cocomplete and in general it is false.
- 3. The free completion  $Sind\mathcal{C}$  of a small category  $\mathcal{C}$  under sifted colimits is obtained from the free completion  $Rec\mathcal{C}$  under reflexive coequalizers by completing it under filtered colimits

$$Sind\mathcal{C} = Ind(Rec\mathcal{C}).$$

This holds whenever C has finite coproducts – and in general it is false.

We begin by describing RecC in a manner analogous to the description of SindC and IndC, see 4.13 and 4.17. A quite different approach to RecC is treated in Chapter 17.

As a special case of Definition 4.9, we get the following

**7.1 Definition.** By a free completion of a category C under reflexive coequalizers is meant a functor  $E_{Rec}: C \to Rec C$  such that

1. Rec C is a category with coequalizers of reflexive pairs

and

2. for every functor  $F: \mathcal{C} \to \mathcal{B}$ , where  $\mathcal{B}$  is a category with reflexive coequalizers, there exists an essentially unique functor  $F^*: \operatorname{Rec} \mathcal{C} \to \mathcal{B}$  preserving reflexive coequalizers with F naturally isomorphic to  $F^* \cdot E_{\operatorname{Rec}}$ .

Recall that for a category  $\mathcal{A}$  we denote by  $\mathcal{A}_{fp}$  the full subcategory of finitely presentable objects.

**7.2 Lemma.** Let  $\mathcal{T}$  be an algebraic theory. The inclusion  $I: (Alg \mathcal{T})_{fp} \to Set^{\mathcal{T}}$  preserves reflexive coequalizers.

**Proof.** This follows from the fact that  $(Alg \mathcal{T})_{fp}$  is closed in  $Alg \mathcal{T}$  under finite colimits (5.11) and that  $Alg \mathcal{T}$  is closed in  $Set^{\mathcal{T}}$  under sifted colimits (2.5), see also 3.2.

**7.3 Theorem.** For every algebraic theory  $\mathcal{T}$  the restricted Yoneda embedding

$$Y_{\mathcal{T}} \colon \mathcal{T}^{op} \to (Alg \mathcal{T})_{fp}$$

is a free completion of  $\mathcal{T}^{op}$  under reflexive coequalizers. In other words,

 $(Alg \mathcal{T})_{fp} = Rec \left( \mathcal{T}^{op} \right).$ 

**Proof.** Recall from 3.2 the category  $\mathcal{M}$ 

$$P \xrightarrow[f_2]{f_1} Q \quad \text{modulo} \quad f_1 \cdot d = \text{id}_Q = f_2 \cdot d \;.$$

We will prove that given a finitely presentable algebra  $A: \mathcal{T} \to Set$ , there exists a final functor (see Definition 2.12)

$$M: \mathcal{M} \to ElA$$
.

The rest of the proof is analogous to the proof of Theorem 4.10: given a functor  $F: \mathcal{T}^{op} \to \mathcal{B}$  where  $\mathcal{B}$  has reflexive coequalizers, we prove that there exists an essentially unique functor

$$F^*: (Alg \mathcal{T})_{fp} \to \mathcal{B}$$

preserving reflexive coequalizers and such that  $F \simeq F^* \cdot Y_T$ . In fact, using the notation of 0.14 for the above final functor M we see that the reflexive coequalizer of  $F \cdot \Phi_A \cdot M(f_i)$  (i = 1, 2) in  $\mathcal{B}$  is just the colimit of  $F \cdot \Phi_A$ , thus, the latter colimit exists, and we are forced to define

$$F^*A = \operatorname{colim}_{ElA} (F \cdot \Phi_A)$$

on objects. This extends uniquely to morphisms (as in the proof of 4.10) and yields a functor  $F^*: (Alg \mathcal{T})_{fp} \to \mathcal{B}$ . Since the inclusion  $I: (Alg \mathcal{T})_{fp} \to Set^{\mathcal{T}}$ preserves reflexive coequalizers (7.2), we have for  $RB = \mathcal{B}(F-, B)$  a bijection

$$\mathcal{B}(F^*A, B) \simeq Set^T(IA, RB)$$

natural in A and B, from which one deduces that  $F^\ast$  preserves reflexive co-equalizers.

To prove the existence of the final functor M, recall from 5.17 that there exists a reflexive pair

$$\overline{P} \xrightarrow{\overline{f_1}} \overline{\overline{d}} \xrightarrow{\overline{d}} \overline{Q}$$

in  $\mathcal{T}$  such that A is a coequalizer of  $Y_{\mathcal{T}}(f_i)$ :

$$Y_{\mathcal{T}}(\overline{P}) \xrightarrow{Y_{\mathcal{T}}(\overline{f_1})} Y_{\mathcal{T}}(\overline{Q}) \xrightarrow{c} A$$

Put  $\overline{c} = c \cdot Y_T(\overline{f_i})$  and define objects of ElA as follows:

$$MP = (\overline{P}, \overline{c}_{\overline{P}}(\mathrm{id}_{\overline{P}})) \text{ and } MQ = (\overline{Q}, c_{\overline{Q}}(\mathrm{id}_{\overline{Q}}))$$

Since clearly  $\overline{f_i}: MP \to MQ$  and  $\overline{d}: MQ \to MP$  are morphisms of ElA, we obtain a functor  $M = \overline{(-)}: \mathcal{M} \to ElA$ . Let us prove its finality:

1. Every object (X, x) of ElA has a morphism into MQ. In fact,

$$c_X \colon \mathcal{T}(\overline{Q}, X) \to AX$$

is an epimorphism, thus, for  $x \in AX$  there exists  $f: \overline{Q} \to X$  with  $c_X(f) = x$ , which implies that  $f: (X, x) \to MQ$  is a morphism of ElA.

2. Given two morphisms of ElA from (X, x) to MP or MQ, they are connected by a zig-zag in the slice category  $(X, x) \downarrow M$ . In fact, we can restrict ourselves to the codomain MQ: the general case is then solved by composing morphisms with codomain MP by  $Mf_1$ .

Given morphisms

$$h, k \colon (X, x) \to MQ$$

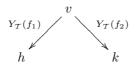

then we have

$$A(h) \cdot c_Q(\mathrm{id}_Q) = x = A(k) \cdot c_Q(\mathrm{id}_Q)$$

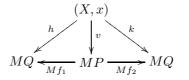

which, due to naturality of c, yields

$$c_X(h) = c_X(k) \,.$$

Now use the description of coequalizers in Set (see 0.6): since  $c_X$  is the coequalizer of  $Y_T(f_1)$  and  $Y_T(f_2)$ , there is a zig-zag of this pair connecting h and k. For example a zig-zag of length 2:

for some  $v: P \to X$ . This means  $h = v \cdot f_1$  and  $k = v \cdot f_2$  and yields the following zig-zag in  $(X, x) \downarrow M$ :

Analogously for longer zig-zags.

**7.4 Corollary.** For a small category C with finite coproducts we have

$$Sind\mathcal{C} = Ind(Rec\mathcal{C}).$$

More precisely, the composition

$$\mathcal{C} \xrightarrow{E_{Rec}} Rec \mathcal{C} \xrightarrow{E_{Ind}} Ind (Rec \mathcal{C})$$

is a free completion of C under sifted colimits.

In fact, for  $\mathcal{T} = \mathcal{C}^{op}$  the above theorem yields  $Rec \mathcal{C} = (Alg \mathcal{T})_{fp}$  from which 6.26 and 4.17 prove  $Ind(Rec \mathcal{C}) = Alg \mathcal{T}$ . Now apply 4.13.

**7.5 Remark.** In the proof of Theorem 7.3 if  $\mathcal{B}$  has finite colimits and F preserves finite coproducts, then the extension  $F^*$  preserves finite colimits. This follows from the fact that  $\mathcal{B}(F-,B)$  lies now in  $Alg\mathcal{T}$  and that  $(Alg\mathcal{T})_{fp}$  is closed in  $Alg\mathcal{T}$  under finite colimits (5.11), so that we have a bijection

$$\mathcal{B}(F^*A, B) \simeq Alg \mathcal{T}(A, \mathcal{B}(F-, B))$$

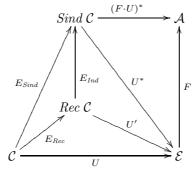

natural in  $A \in (Alg \mathcal{T})_{fp}$  and  $B \in \mathcal{B}$ .

**7.6 Remark.** In the introduction to this chapter we claimed that a functor defined on a finitely cocomplete category preserves sifted colimits iff it preserves filtered colimits and reflexive coequalizers. The proof of this result can be found in [11], here we present a (simpler) proof based on 7.4 which requires cocompleteness of both categories (in fact, sifted colimits are enough as far as the codomain category is concerned).

**7.7 Theorem.** A functor between cocomplete categories preserves sifted colimits if and only if it preserves filtered colimits and reflexive coequalizers.

**Proof.** Necessity is clear. To prove sufficiency, let  $F: \mathcal{E} \to \mathcal{A}$  preserve filtered colimits and reflexive coequalizers where  $\mathcal{E}$  and  $\mathcal{A}$  are cocomplete. For every sifted diagram  $D: \mathcal{D} \to \mathcal{E}$  choose a small full subcategory  $U: \mathcal{C} \hookrightarrow \mathcal{E}$  containing

the image of D and closed in  ${\mathcal E}$  under finite coproducts. Consider the following diagram

where  $U^*$  and  $(F \cdot U)^*$  are the extensions of U and  $F \cdot U$ , respectively, preserving sifted colimits, and U' is the extension of U preserving reflexive coequalizers. Since by 7.4 we have  $E_{Sind} = E_{Ind} \cdot E_{Rec}$ , it follows that

$$(F \cdot U)^* \cdot E_{Ind} \cdot E_{Rec} \simeq (F \cdot U)^* \cdot E_{Sind} \simeq F \cdot U \simeq F \cdot U' \cdot E_{Rec}$$

The functor  $E_{Ind}$  preserves reflexive coequalizers by 4.16 and 4.17, and so do the functors F, U' and  $(F \cdot U)^*$ . Thus, the universal property of  $E_{Rec}$  yields

$$(F \cdot U)^* \cdot E_{Ind} \simeq F \cdot U'.$$

Since

$$U^* \cdot E_{Ind} \cdot E_{Rec} \simeq U^* \cdot E_{Sind} \simeq U \simeq U' \cdot E_{Rec}$$

and, once again, the functors  $U^*, E_{Ind}$  and U' preserve reflexive coequalizers, we have

$$U^* \cdot E_{Ind} \simeq U'$$

Finally, since

$$F \cdot U^* \cdot E_{Ind} \simeq F \cdot U' \simeq (F \cdot U)^* \cdot E_{Ind}$$

and the functors  $F, U^*$  and  $(F \cdot U)^*$  preserve filtered colimits, we have

$$F \cdot U^* \simeq (F \cdot U)^* \,. \tag{7.1}$$

We are ready to prove  $F(colim D) \simeq colim (F \cdot D)$ . Let

$$D': \mathcal{D} \to \mathcal{C} \quad \text{with} \quad D = U \cdot D'$$

be the codomain restriction of D. Then

$$F \cdot D = F \cdot U \cdot D' \simeq (F \cdot U)^* \cdot E_{Sind} \cdot D'$$

implies, since  $(F \cdot U)^*$  preserves the sifted colimit of  $E_{Sind} \cdot D'$ , that

$$colim(F \cdot D) \simeq (F \cdot U^*)(colim(E_{Sind} \cdot D')).$$

From [7.1] and the fact that  $U^*$  also preserves the sifted colimit of  $E_{Sind} \cdot D'$  we derive

$$colim(F \cdot D) \simeq F(colim(U^* \cdot E_{Sind} \cdot D')) \simeq F(colim D).$$

**7.8 Remark.** We thus established proofs of the affirmative statements 2. and 3. of the introduction of this chapter. The statement 1. is easy: if C has filtered colimits, reflexive coequalizers, and finite coproducts, then it has all colimits (4.1).

With the following examples we demonstrate the negative parts of the statements 1.–3.

**7.9 Example.** Here we give an example of a category not having sifted colimits although it has (i) filtered colimits and (ii) reflexive coequalizers.

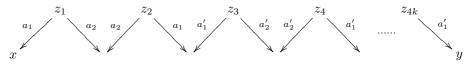

We start with the following category  $\mathcal{D}$  given by the gluing of two reflexive pairs at their codomains. That is,  $\mathcal{D}$  is given by the graph

$$A \xrightarrow[a_2]{a_1} B \xrightarrow[a_1']{a_1'} A'$$

and the equations making both parallel pairs reflexive:

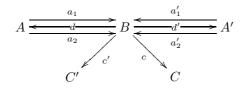

$$a_i \cdot d = \mathrm{id}_B = a'_i \cdot d'$$
 for  $i = 1, 2$ .

The proof that  $\mathcal{D}$  is sifted is completely analogous to the proof of 3.2: we verify that colimits over  $\mathcal{D}$  in *Set* commute with finite products. Assume that the above graph depicts sets A, B and A' and functions between them. Then a colimit can be described as the canonical function  $c: B \to C = B/\sim$  where two elements  $x, y \in B$  are equivalent iff they are connected by a zig-zag formed by  $a_1, a_2, a'_1$  and  $a'_2$ . Since the two pairs are reflexive, the length of the zig-zag can be arbitrarily prolonged. And the type can be chosen to be

(here for the elements  $z_{4i+1}$  we use  $a_1, a_2$ , for  $z_{4i+2}$  we use  $a_2, a_1$ , for  $z_{4i+3}$  we use  $a'_1, a'_2$  and for  $z_{4i}$  we use  $a'_2, a'_1$ ). From that it is easy to derive that  $\mathcal{D}$  is sifted.

We now add to  $\mathcal{D}$  the coequalizers  $c_1$  of  $a_1, a_2$  and c' of  $a'_1, a'_2$ : let  $\mathcal{E}$  be the category given by the graph

February 1, 2010

68

with the previous equations plus the following ones

$$c \cdot a_1 = c \cdot a_2$$
 and  $c' \cdot a'_1 = c' \cdot a'_2$ .

The sifted diagram  $\mathcal{D} \to \mathcal{E}$  which is the inclusion does not have a colimit. However,  $\mathcal{E}$  has reflexive coequalizers because its only nontrivial reflexive pairs are  $a_1, a_2$  (with coequalizer c) and  $a'_1, a'_2$  (with coequalizer c'). Moreover,  $\mathcal{E}$  has filtered colimits: since the category  $\mathcal{E}$  is clearly finite, it does not have any nontrivial filtered diagram except those obtained by iterating an idempotent endomorphism e, see 2.3. Thus it is sufficient to verify that  $\mathcal{E}$  has coequalizers of all pairs  $e, \operatorname{id}_X$  where e is an idempotent endomorphism of X. In fact, the only idempotents of  $\mathcal{E}$  are  $d \cdot a_i$  and  $d' \cdot a'_i$ . The coequalizer of  $d \cdot a_1$  and  $\operatorname{id}_A$  is clearly  $a_1$  (because a morphism f with  $f = f \cdot d \cdot a_1$  fulfils  $f \neq a_2$  and then it uniquely factorizes through  $a_1$ ), analogously for the other three idempotents. Thus, the above coequalizers demonstrate that  $\mathcal{E}$  has filtered colimits.

**7.10 Remark.** For the category  $\mathcal{D}$  of 7.9 we have

$$Sind \mathcal{D} \neq Ind (Rec \mathcal{D}).$$

Observe first that

 $\operatorname{Rec} \mathcal{D} = \mathcal{E}$ 

is obtained from  $\mathcal{D}$  by freely adding the coequalizers c and c'. The category  $Ind\mathcal{E}$  does not have a terminal object. In fact, the full subcategory of all objects X in  $Ind\mathcal{E}$  having a morphism from at most one of the objects C or C' into X is clearly closed under filtered colimits – thus every object X has that property. In contrast,  $Sind\mathcal{D}$  has the terminal object  $colim\mathcal{D}$ .

**7.11 Example.** Here we give an example of a functor not preserving sifted colimits although it preserves (i) filtered colimits and (ii) reflexive coequalizers. Let  $\mathcal{E}^T$  be the above category  $\mathcal{E}$  with a terminal object T added. The sifted diagram  $D: \mathcal{D} \to \mathcal{E}^T$  which is the inclusion has colimit

$$T = colim D$$

in  $\mathcal{E}^T.$  Let  $\mathcal A$  be the category  $\mathcal{E}^T$  with a new terminal objects S added. The functor

$$F: \mathcal{E}^T \to \mathcal{A}$$
 with  $FT = S$  and  $FX = X$  for all  $X \neq T$ 

which is the identity map on morphisms of  $\mathcal{E}$  does not preserve sifted colimits because

$$F(\operatorname{colim} D) = S$$
 and  $\operatorname{colim} F \cdot D = T$ .

However, F clearly preserves filtered colimits and reflexive coequalizers: the only nontrivial colimits of these types in  $\mathcal{E}^T$  lie in  $\mathcal{E}$  and are described in Example 7.9. The same description applies to  $\mathcal{A}$ .

**7.12 Example.** Since  $\mathcal{N}$  is a theory of *Set*, see 1.4, we have

$$Set = Ind Rec \mathcal{N}$$
.

Let us observe that in the opposite direction we do not obtain an equality: the canonical morphism from  $Rec Ind \mathcal{N}$  to Set is not an equivalence. In fact, it is easy to see that that  $Ind \mathcal{N}$  can be represented as Set. And the free completion Rec Set of Set under reflexive coequalizers is not an equivalence. To demonstrate this it is sufficient to present an arbitrary functor with domain Set which does not preserve reflexive coequalizers.

One such example is  $Set(\mathbb{N}, -)$ . In fact, consider the parallel pair

$$\mathbb{N} + \mathbb{N} \xrightarrow{u}_{v} \mathbb{N}$$

having the left-hand components  $\mathrm{id}_{\mathbb{N}}$  and the right-hand ones  $\mathrm{id}_{\mathbb{N}}$  and s, the successor function, respectively. Due to the left-hand components this is a reflexive pair, due to the right-hand ones their coequalizer has then terminal codomain 1. However, the coequalizer of  $u^{\mathbb{N}}, v^{\mathbb{N}}$  does not merge the elements  $(0, 0, 0, \ldots)$  and  $(0, 1, 2, \ldots)$  of  $\mathbb{N}^{\mathbb{N}}$ , therefore its codomain is not  $1^{\mathbb{N}} \simeq 1$ .

#### Historical Remarks for Chapter 7

The open problem of [9] whether preservation of filtered colimits and reflexive coequalizers implies preservation of sifted colimits was answered by A. Joyal; his proof even works for quasi-categories (see [55]). Another proof was given S. Lack (see [57]). The present proof is taken from [11] where also the stronger statements stated at the beginning of this chapter are proved.

The formula 7.4 stems from [9].

## Chapter 8

# **Canonical theories**

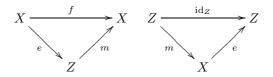

Every algebraic category has a number of algebraic theories which are often non-equivalent, we will study this more detailed in Chapter 15. In the present chapter we prove that there is always an essentially unique algebraic theory with split idempotents. We call it a canonical theory. This is the idempotent completion (also known as Cauchy completion) of any algebraic theory of the given category. We first discuss splitting of idempotents and idempotent completions.

#### 8.1 Definition.

1. Given an idempotent morphism

$$f \colon X \to X$$
,  $f \cdot f = f$ 

in a category C, by a *splitting* of f is meant a factorization  $f = m \cdot e$  such that  $e \cdot m$  is the identity morphism:

2. A category C is called *idempotent-complete* provided that every idempotent in C has a splitting.

#### 8.2 Remark.

- 1. A splitting of an idempotent f is unique up to isomorphism:
  - (a) for every isomorphism  $i: Z \to \overline{Z}$  the morphisms  $\overline{e} = i \cdot e$  and  $\overline{m} = m \cdot i^{-1}$  form a splitting of f, and
  - (b) for every splitting  $f = \overline{m} \cdot \overline{e}$ ,  $\overline{e} \cdot \overline{m} = \text{id}$ , there exists a unique isomorphism i such that  $i \cdot e = \overline{e}$  and  $m \cdot i^{-1} = \overline{m}$  (just put  $i = \overline{e} \cdot m$  and  $i^{-1} = e \cdot \overline{m}$ ).

2. To be idempotent-complete is a self-dual notion:  ${\mathcal C}$  is idempotent complete iff  ${\mathcal C}^{op}$  is so.

#### 8.3 Example.

1. Every category which has equalizers is idempotent-complete. In fact, form an equalizer m of the idempotent  $f: X \to X$  and id:  $X \to X$ 

$$Z \xrightarrow{m} X \xrightarrow{f} X$$

Since  $f \cdot f = \operatorname{id} \cdot f$ , the morphism f factorizes as  $f = m \cdot e$  for some  $e \colon X \to Z$ . Now,  $m \cdot e \cdot m = f \cdot m = m$  and m is a monomorphism, so that  $e \cdot m = \operatorname{id}$ .

Conversely, if an idempotent  $f\colon X\to X$  splits as  $f=m\cdot e,$  then m is an equalizer of f and  $\mathrm{id}_X$  .

- 2. Every category with coequalizers is also idempotent-complete. Conversely, if an idempotent  $f: X \to X$  splits as  $f = m \cdot e$ , then e is a coequalizer of f and  $id_X$ . This is the dualization of 1.
- 3. A full subcategory of an idempotent-complete category C is idempotent-complete iff it is closed in C under retracts.
- **8.4 Definition.** By an *idempotent completion of a category* C is meant a functor

$$E_{Ic}: \mathcal{C} \to Ic \mathcal{C}$$

such that

1. IcC is idempotent-complete

and

2. for every functor  $F: \mathcal{C} \to \mathcal{B}$ , where  $\mathcal{B}$  is an idempotent-complete category, there exists an essentially unique functor  $F^*: Ic\mathcal{C} \to \mathcal{B}$  with F naturally isomorphic to  $F^* \cdot E_{Ic}$ .

#### 8.5 Remark.

- 1. A category C is idempotent-complete iff the functor  $E_{Ic}: C \to IcC$  is an equivalence.
- 2. Clearly,  $Ic(\mathcal{C}^{op}) \simeq (Ic\mathcal{C})^{op}$ .

We give now an elementary description of Ic C.

**8.6 Definition.** For every category C we denote by IcC the category of idempotents: its objects are the idempotent morphisms of C. Its morphisms from

February 1, 2010 72

 $f: X \to X$  to  $g: Z \to Z$  are the morphisms  $a: X \to Z$  in  $\mathcal{C}$  such that  $a = g \cdot a \cdot f$  or, equivalently, such that the diagram

commutes. The identity of the object  $f: X \to X$  is f itself, and composition is as in  $\mathcal{C}$ .

We have a full and faithful functor  $E_{Ic} : \mathcal{C} \to Ic\mathcal{C}$  defined by  $E_{Ic}(X) = \mathrm{id}_X$ and  $E_{Ic}(a) = a$ .

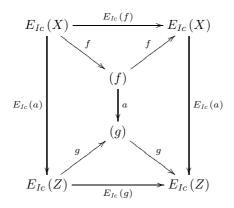

**8.7 Proposition.** The functor  $E_{Ic} : \mathcal{C} \to Ic\mathcal{C}$  defined in 8.6 is an idempotent completion of  $\mathcal{C}$ .

**Proof.** 1.  $Ic\mathcal{C}$  is idempotent-complete: let a be an idempotent endomorphism of  $(f: X \to X)$  in  $Ic\mathcal{C}$ . A splitting of a is given by

$$(f\colon X\to X) \xrightarrow{a} (a\colon X\to X) \xrightarrow{a} (f\colon X\to X)$$

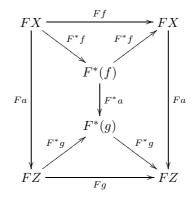

2. Consider a functor  $F: \mathcal{C} \to \mathcal{B}$  with  $\mathcal{B}$  idempotent-complete. Every object  $(f: X \to X)$  of  $Ic\mathcal{C}$  is obtained by splitting the idempotent  $f: E_{Ic}(X) \to E_{Ic}(X)$ . Thus, we are forced to define  $F^*$  on objects  $f: X \to X$  as the (essentially unique) splitting of  $Ff: FX \to FX$  in  $\mathcal{B}$ .

To define  $F^*$  on morphisms  $a: (f: X \to X) \to (g: Z \to Z)$  in  $Ic\mathcal{C}$ , observe that a is the unique morphism making the following diagram

commutative in  $Ic \mathcal{C}$ . Thus, we are forced to define  $F^*(a)$  as the unique morphism

making the following diagram

commutative in  $\mathcal{B}$ . Explicitly:

$$F^*a: F^*(f) \xrightarrow{F^*f} FX \xrightarrow{Fa} FZ \xrightarrow{F^*g} F^*(g)$$
.

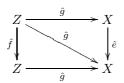

It is easy to verify that this yields a well-defined functor  $F^*$  with  $F^* \cdot I \simeq F$ .

**8.8 Proposition.** For every small category C an idempotent completion of  $C^{op}$  is the codomain restriction of the Yoneda embedding  $Y_C : C^{op} \to Set^C$  to the full subcategory of all absolutely presentable objects of  $Set^C$ .

**Proof.** Recall from 5.10 that a functor  $\mathcal{C} \to Set$  is absolutely presentable iff it is a retract of a representable one. To prove that the full subcategory of all absolutely presentable objects of  $Set^{\mathcal{C}}$  is equivalent to the category  $Ic(\mathcal{C}^{op})$  of 8.6, consider two retracts

$$R \stackrel{e}{\underset{m}{\longleftarrow}} Y_{\mathcal{C}}(X) , \ e \cdot m = \mathrm{id}_R \quad \text{and} \quad S \stackrel{f}{\underset{n}{\longleftarrow}} Y_{\mathcal{C}}(Z) , \ f \cdot n = \mathrm{id}_S$$

and a morphism  $g: R \to S$  in  $Set^{\mathcal{C}}$ . By the Yoneda Lemma, we get two idempotents  $\hat{e} = m \cdot e(\operatorname{id}_X)$  and  $\hat{f} = n \cdot f(\operatorname{id}_Z)$  in  $\mathcal{C}$  and a morphism  $\hat{g} = n \cdot g \cdot e(\operatorname{id}_X)$  forming a commutative diagram

This is a morphism in the category  $Ic(\mathcal{C}^{op})$ . The rest of the proof is straightforward.

**8.9 Corollary.** For every algebraic theory  $\mathcal{T}$  the Yoneda embedding

$$Y_{\mathcal{T}}: \mathcal{T}^{op} \to (Alg \mathcal{T})_{pp}$$

is an idempotent completion of  $\mathcal{T}^{op}$ . In other words,  $(Alg \mathcal{T})_{pp} \simeq Ic(\mathcal{T}^{op})$ .

In fact, by 5.10 and 8.8,  $Ic(\mathcal{T}^{op})$  is formed by retracts of representables in  $Set^{\mathcal{T}}$ , that is, by perfectly presentable objects in  $Alg\mathcal{T}$  (see 5.14).

**8.10 Corollary.** For two small categories C and D the corresponding functor categories Set<sup>C</sup> and Set<sup>D</sup> are equivalent if and only if C and D have a common idempotent completion:

$$Set^{\mathcal{C}} \simeq Set^{\mathcal{D}}$$
 iff  $Ic \mathcal{C} \simeq Ic \mathcal{D}$ .

**Proof.** The universal property of  $E_{Ic}: \mathcal{C} \to Ic\mathcal{C}$  clearly implies  $Set^{\mathcal{C}} \simeq Set^{Ic\mathcal{C}}$ .

Conversely, if  $Set^{\mathcal{C}} \simeq Set^{\mathcal{D}}$ , then the subcategories of absolutely presentable objects are equivalent. By 5.10 and 8.8, this means that  $Ic(\mathcal{C}^{op}) \simeq Ic(\mathcal{D}^{op})$ . Now use duality, or 8.5.2.

**8.11 Definition.** Let  $\mathcal{A}$  be an algebraic category. An algebraic theory for  $\mathcal{A}$  is called *canonical* if it is idempotent-complete.

**8.12 Proposition.** Every algebraic category  $\mathcal{A}$  has a canonical theory unique up to equivalence. The dual of  $\mathcal{A}_{pp}$  (see 6.12) is a canonical theory for  $\mathcal{A}$ .

**Proof.** Following 6.13,  $\mathcal{A} \simeq Alg(\mathcal{A}_{pp}^{op})$ . By 5.14 and 8.3,  $\mathcal{A}_{pp}$  is idempotentcomplete, and then  $\mathcal{A}_{pp}^{op}$  is also idempotent-complete, see 8.2. Let us verify the uniqueness. If  $\mathcal{A} \simeq Alg\mathcal{T}$  for some algebraic theory  $\mathcal{T}$ , then  $\mathcal{A}_{pp} \simeq (Alg\mathcal{T})_{pp} \simeq$  $Ic(\mathcal{T}^{op})$  by 6.14 and 8.9. Finally,  $\mathcal{A}_{pp}^{op} \simeq Ic\mathcal{T}$  by 8.5.

#### 8.13 Example.

- 1. The canonical theory of the category Set is the theory  $\mathcal{N}$  of natural numbers, see 1.4: it is clear that  $\mathcal{N}$  is idempotent-complete.
- 2. The canonical theory of the category Ab is the theory  $\mathcal{T}_{ab}$  described in 1.20. In fact, we saw in 5.6 that  $\mathcal{T}_{ab}$  is dual to  $Ab_{pp}$ .
- 3. In the category *Bool* of boolean algebras we have the algebras  $\mathcal{P}X$  of all subsets of a set X. The free algebras on n generators  $\mathcal{PP}n$  form, for  $n \in \mathbb{N}$ , a strong generator. As noted in 6.10, the dual of this full subcategory of *Bool* is a theory for *Bool*. However, this is not the canonical theory. In fact, the canonical theory is the dual of the full subcategory of all algebras  $\mathcal{P}n$  for  $n \in \mathbb{N} \setminus \{0\}$ , or equivalently, the category of finite nonempty sets and functions. Since each n > 0 is injective in the category of finite sets, it is a retract of  $2^n$ . Thus  $\mathcal{P}n$  is a retract of  $\mathcal{PP}n$ .

#### Historical Remarks for Chapter 8

The idempotent completion can already be found in B. Mitchell's monograph [72]. M. Bunge [31] presented it as well and used it for proving Corollary 8.10. She called it idempotent splitting closure; other names were used as well, e.g. Cauchy completion or Karoubi envelope. Corollary 8.10 was later proved in [43]. Proposition 8.12 is due to J. J. Dukarm [39].

CHAPTER 8. CANONICAL THEORIES

### Chapter 9

# Algebraic functors

We have studied algebraic categories as individual categories so far. It turns out that there is a natural concept of morphism between algebraic categories, which we call an algebraic functor, so that we obtain a 2-category of all algebraic categories. We then prove a duality result: this 2-category is biequivalent to the 2-category of algebraic theories. We first need to introduce a concept of morphism between algebraic categories – this is quite obvious:

**9.1 Definition.** Let  $\mathcal{T}_1$  and  $\mathcal{T}_2$  be algebraic theories. A functor  $M: \mathcal{T}_1 \to \mathcal{T}_2$  is called a *morphism of algebraic theories* if it preserves finite products.

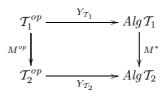

**9.2 Notation.** For a morphism of theories  $M: \mathcal{T}_1 \to \mathcal{T}_2$  we denote by

$$Alg M: Alg \mathcal{T}_2 \to Alg \mathcal{T}_1$$

the functor defined on objects  $A: \mathcal{T}_2 \to Set$  by  $A \mapsto A \cdot M$ .

**9.3 Proposition.** Let  $M: \mathcal{T}_1 \to \mathcal{T}_2$  be a morphism of algebraic theories.

- 1. Alg M: Alg  $\mathcal{T}_2 \rightarrow Alg \mathcal{T}_1$  preserves limits and sifted colimits.
- 2. Alg M has a left adjoint  $M^*$ : Alg  $\mathcal{T}_1 \to Alg \mathcal{T}_2$  which is the essentially unique functor which preserves sifted colimits and makes the square

commutative up to natural isomorphism.

**Proof.** The essentially unique functor  $M^*$  follows from Theorem 4.13. Since  $Y_{\mathcal{T}_2} \cdot M^{op}$  preserves finite coproducts, see Lemma 1.13, to get the adjunction  $M^* \dashv Alg M$  it suffices to apply 4.15: the right adjoint Alg M is given by

$$B \mapsto Alg \mathcal{T}_2(Y_{\mathcal{T}_2}(M-), B)$$

By the Yoneda Lemma, this is nothing but composition with M. This immediately implies that AlgM preserves sifted colimits, because they are calculated objectwise in  $AlgT_1$  and  $AlgT_2$  (see 2.5).

**9.4 Definition.** A functor between two algebraic categories is called *algebraic* provided that it preserves limits and sifted colimits.

#### 9.5 Example.

- 1. Every functor Alg M, for a theory morphism M, is algebraic.
- 2. The forgetful functor  $Ab \rightarrow Set$  is algebraic.
- 3. Given an algebra A in an algebraic category A, then  $\mathcal{A}(A, -): A \to Set$  is algebraic iff A is perfectly presentable.
- 4. A constant functor with value A between algebraic categories is algebraic iff A is a terminal object.
- 5. For every algebraic theory  $\mathcal{T}$ , the embedding  $I: Alg \mathcal{T} \to Set^{\mathcal{T}}$  is an algebraic functor, see 1.21 and 2.5.

**9.6 Remark.** We know from 9.3 that every morphism of theories induces an algebraic functor between the corresponding algebraic categories. If, moreover, the algebraic theories are canonical (8.11), then the algebraic functors are essentially just those induced by morphisms of theories, see 9.15 below. This will motivate us to define "morphisms of algebraic categories" as the algebraic functors. We are now going to prove that every algebraic functor has a left adjoint. For this we will use Freyd's Adjoint Functor Theorem (see 0.8).

**9.7 Theorem.** A functor between algebraic categories is algebraic if and only if it has a left adjoint and preserves sifted colimits.

**Proof.** Let  $G: \mathcal{B} \to \mathcal{A}$  be an algebraic functor. We are to prove that G has a left adjoint. That is, for every object A of  $\mathcal{A}$  we are to prove that the functor

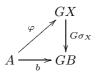

$$\mathcal{A}(A, G-) \colon \mathcal{B} \to Set$$

is representable.

(1) Assume first that A is perfectly presentable. Since G preserves limits, it remains to prove that  $\mathcal{A}(A, G-)$  satisfies the Solution Set Condition of 0.10. For  $\mathcal{B}_{pp}$  in 6.12 put

$$\mathcal{G} = \{ GX \mid X \in \mathcal{B}_{pp} \}.$$

Every object B of  $\mathcal{B}$  is a sifted colimit of objects from  $\mathcal{B}_{pp}$  (see 6.9). Let us write  $(\sigma_X \colon X \to B)$  for the colimit cocone. Since G preserves sifted colimits,  $(G\sigma_X \colon GX \to GB)$  is also a colimit cocone. As  $\mathcal{A}(A, -)$  preserves sifted colimits, every morphism  $b \colon A \to GB$  factorizes as follows

February 1, 2010

78

#### CHAPTER 9. ALGEBRAIC FUNCTORS

Thus all  $G(\sigma_X)$  form a solution set.

(2) If A is an arbitrary object of  $\mathcal{A}$ , we express it as a sifted colimit of perfectly presentable objects (see 6.9), say  $A = \operatorname{colim} A_i$ . From (1) we know that  $\mathcal{A}(A_i, G-)$  is representable, say  $\mathcal{A}(A_i, G-) \simeq \mathcal{B}(B_i, -)$ . Yoneda Lemma now allows us to define an (obvious) sifted diagram whose objects are the  $B_i$ . Therefore,  $\mathcal{A}(A_i, G-)$  is representable by  $\operatorname{colim} B_i$  since

$$\mathcal{A}(A,G-) = \mathcal{A}(\operatorname{colim} A_i,G-) \simeq \lim \mathcal{A}(A_i,G-) \simeq \lim \mathcal{B}(B_i,-) \simeq \mathcal{B}(\operatorname{colim} B_i,-).$$

**9.8 Remark.** The previous theorem can be refined, as we demonstrate in Chapter 18: a functor between algebraic categories is algebraic if and only if it preserves limits, filtered colimits and regular epimorphisms. One implication follows from the fact that: a) filtered implies sifted, and b) every regular epimorphism is a reflexive coequalizer (of its kernel pair). The converse implication is a particular case of 18.2.

**9.9 Remark.** We are going to prove a duality between algebraic categories and canonical algebraic theories. This does not really mean a contravariant equivalence of categories. Indeed, a more subtle formulation is needed: just look at the simplest algebraic category, *Set*, and the simplest endomorphism, the identity functor  $Id_{Set}$ . It is easy to find a proper class of functors naturally isomorphic to  $Id_{Set}$  – and each of them is algebraic. However, in the category of all theories no such phenomenon occurs. We thus need to work with morphisms of algebraic categories "up to natural isomorphism". For this reason we have to move from categories to 2-categories. The reader does not need to know much about 2-categories. Here we summerize the needed facts.

#### 9.10 A primer on 2-categories.

1. Let us recall that a 2-category A has a class obj A of objects and, instead of hom-sets A(A, B), it has hom-categories A(A, B) for every pair A, B of objects. The objects of A(A, B) are called 1-cells and the morphisms 2-cells. Composition is represented by functors

$$c_{A,B,C} \colon \mathbb{A}(A,B) \times \mathbb{A}(B,C) \to \mathbb{A}(A,C)$$

which are associative in the expected sense: the two canonical functors

$$c_{A,B,D} \cdot (\mathbb{A}(A,B) \times c_{B,C,D})$$
 and  $c_{A,C,D} \cdot (c_{A,B,C} \times \mathbb{A}(C,D))$ 

from  $\mathbb{A}(A, B) \times \mathbb{A}(B, C) \times \mathbb{A}(C, D)$  into  $\mathbb{A}(A, D)$  are required to be equal. The identity morphisms are represented by functors

$$i_A \colon \mathbb{I} \to \mathbb{A}(A, A)$$

(where  $\mathbb I$  is the one-morphism category) which fulfil the usual requirements: both of the composites

$$c_{A,A,B} \cdot (i_A \times \mathbb{A}(A,B)) \colon \mathbb{I} \times \mathbb{A}(A,B) \to \mathbb{A}(A,B)$$

and

$$c_{A,B,B} \cdot (\mathbb{A}(A,B) \times i_B) \colon \mathbb{A}(A,B) \times \mathbb{I} \to \mathbb{A}(A,B)$$

are the canonical isomorphisms.

- 2. A prototype of a 2-category is the 2-category *Cat* of all small categories (as objects). Given small categories *A*, *B*, then 1-cells are functors from *A* to *B* and 2-cells are natural transformations. In our book, we essentially work just with this 2-category and its sub-2-categories (see 4).
- 3. Let us recall the concept of a 2-functor  $F \colon \mathbb{A} \to \mathbb{B}$  between 2-categories  $\mathbb{A}$  and  $\mathbb{B}$ : it assigns objects FA of  $\mathbb{B}$  to objects A of  $\mathbb{A}$ ; for every pair A, A' of objects of  $\mathbb{A}$ , it defines a functor

$$F_{A,A'} \colon \mathbb{A}(A,A') \to \mathbb{B}(FA,FA')$$
.

Preservation of composition is expressed by the requirement that the two canonical functors

$$F_{A,C} \cdot c_{A,B,C}$$
 and  $c_{FA,FB,FC} \cdot (F_{A,B} \times F_{B,C})$ 

from  $\mathbb{A}(A, B) \times \mathbb{A}(B, C)$  into  $\mathbb{B}(FA, FC)$  are equal. Preservation of identity morphisms is expressed by

$$F_{A,A} \cdot i_A = i_{FA} \colon \mathbb{I} \to \mathbb{B}(FA, FA)$$
.

- 4. A sub-2-category  $\mathbb{A}$  of a 2-category  $\mathbb{B}$  is given by a choice of a class of objects  $\operatorname{obj} \mathbb{A} \subseteq \operatorname{obj} \mathbb{B}$  and, for every pair  $A, A' \in \operatorname{obj} \mathbb{A}$ , of a subcategory  $\mathbb{A}(A, A') \subseteq \mathbb{B}(A, A')$  such that compositions and identites functors of  $\mathbb{B}$  restrict to  $\mathbb{A}$ . The inclusion  $I \colon \mathbb{A} \to \mathbb{B}$  is a 2-functor. The sub-2-category is full if  $\mathbb{A}(A, A') = \mathbb{B}(A, A')$ .
- 5. Two objects A, B of a 2-category  $\mathbb{A}$  are called *equivalent* if there exist 1-cells  $f: A \to B$  and  $\overline{f}: B \to A$  such that  $\overline{f} \cdot f$  is isomorphic to  $\mathrm{id}_A$  in  $\mathbb{A}(A, A)$  and  $f \cdot \overline{f}$  is isomorphic to  $\mathrm{id}_B$  in  $\mathbb{A}(B, B)$ .
- 6. A 2-functor  $F \colon \mathbb{A} \to \mathbb{B}$  is called a *biequivalence* if all the functors  $F_{A,A'}$  are equivalence functors, and every object of  $\mathbb{B}$  is equivalent to FA for some object A of  $\mathbb{A}$ .
- 7. In contrast with equivalences of categories (see 0.2 and 0.3), if  $F: \mathbb{A} \to \mathbb{B}$  is a biequivalence, then the quasi-inverses  $F': \mathbb{B} \to \mathbb{A}$  are no longer 2-functors, but just homomorphisms of 2-categories as defined in [24]. This means that the canonical requirements about compositions and identities are fulfilled by F' only up to invertible 2-cells.
- 8. For every 2-category  $\mathbb{A}$  we denote by  $\mathbb{A}^{op}$  the *dual 2-category*: it has the same objects and the direction of 1-cells is reversed (while the direction of 2-cells remains non-reversed):  $\mathbb{A}^{op}(A, A') = \mathbb{A}(A', A)$ .

#### 9.11 Definition.

1. The 2-category Th of theories has

objects: algebraic theories,

1-cells: morphisms of algebraic theories,

2-cells: natural transformations.

This is a sub-2-category of Cat, i.e., composition of 1-cells and 2-cells are defined in Th as the usual composition of functors and natural transformations, respectively.

- 2. The 2-category  $Th_c$  of canonical theories is the full sub-2-category of Th on all theories that are canonical, that is, idempotent-complete.
- 3. The 2-category ALG of algebraic categories has

objects: algebraic categories,

1-cells: algebraic functors,

2-cells: natural transformations.

Once again, composition is the usual composition of functors or natural transformations.

**9.12 Remark.** We need to be a little careful about foundations here: there is, as remarked above, a proper class of 1-cells in ALG(Set, Set), for example. However, if we consider the 1-cells up to natural isomorphism, all problems disappear: this is one consequence of the duality theorem below. Ignoring the foundational considerations, we consider ALG as a sub-2-category of the 2-category of all categories. (The duality we prove below tells us that ALG is essentially just the dual of  $Th_{c.}$ )

9.13 Definition. We denote by

$$Alg: Th^{op} \to ALG$$

the 2-functor assigning to every algebraic theory  $\mathcal{T}$  the category  $Alg\mathcal{T}$ , to every 1-cell  $M: \mathcal{T}_1 \to \mathcal{T}_2$  the functor  $AlgM = (-) \cdot M$  and to every 2-cell  $\alpha: M \to N$ the natural transformation  $Alg\alpha: AlgM \to AlgN$  whose component at a  $\mathcal{T}_2$ algebra A is  $A \cdot \alpha: A \cdot M \to A \cdot N$ .

**9.14 Remark.** The 2-functor Alg is well-defined due to 9.3: for every morphism of theories M, the functor Alg M is algebraic. The fact that for every natural transformation  $\alpha$  we get a natural transformation  $Alg \alpha$  is easy to verify.

**9.15 Theorem.** (Duality of algebraic categories and theories) The 2-category ALG of algebraic categories is biequivalent to the dual of the 2-category  $Th_c$  of canonical algebraic theories.

In fact, the domain restriction of the 2-functor Alg to canonical algebraic theories

$$Alg: Th_c^{op} \to ALG$$

is a biequivalence.

**Proof.** (1) Following 8.12, every algebraic category  $\mathcal{A}$  is equivalent to  $Alg\mathcal{T}$  for the canonical algebraic theory  $\mathcal{T} = \mathcal{A}_{pp}^{op}$ .

(2) We will prove that for two canonical algebraic theories  $\mathcal{T}_1$  and  $\mathcal{T}_2$  the functor

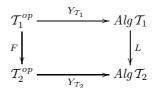

$$Alg_{\mathcal{T}_1,\mathcal{T}_2} \colon Th_c(\mathcal{T}_1,\mathcal{T}_2) \to ALG(Alg\mathcal{T}_2,Alg\mathcal{T}_1)$$

is an equivalence of categories.

(2a)  $Alg_{\mathcal{T}_1,\mathcal{T}_2}$  is full and faithful: given morphisms  $M, N: \mathcal{T}_1 \rightrightarrows \mathcal{T}_2$  and a natural transformation  $\lambda: Alg M \rightarrow Alg N$  there exists a unique natural transformation  $\alpha: M \rightarrow N$  such that  $Alg \alpha = \lambda$ . The proof follows the lines of the proof of Yoneda Lemma. Let us just indicate how to construct  $\alpha$ . Consider an object X in  $\mathcal{T}_1$ . Since  $\mathcal{T}_2(MX, -) \in Alg \mathcal{T}_2$ , we have the component  $\lambda_{\mathcal{T}_2(MX, -)}(X): \mathcal{T}_2(MX, MX) \rightarrow \mathcal{T}_2(MX, NX)$  and we put

$$\alpha_X = \lambda_{\mathcal{T}_2(MX, -)}(X)(\mathrm{id}_{MX}) \colon MX \to NX.$$

The family  $(\alpha_X)_{X \in \mathcal{T}_1}$  is the required natural transformation  $\alpha \colon M \to N$ . (2b) The functor  $Alg_{\mathcal{T}_1,\mathcal{T}_2}$  is essentially surjective. In fact, consider an algebraic functor  $G \colon Alg\mathcal{T}_2 \to Alg\mathcal{T}_1$  and let L be its left adjoint, see 9.7. We are going to prove that L restricts to a functor F which preserves finite coproducts and makes the square

commutative up to natural isomorphism. For every object X in  $\mathcal{T}_1$  we have by adjunction a natural isomorphism

$$Alg \mathcal{T}_2(L(Y_{\mathcal{T}_1}(X)), -) \simeq Alg \mathcal{T}_1(Y_{\mathcal{T}_1}(X), G-).$$

Since  $Y_{\mathcal{T}_1}(X)$  is perfectly presentable (see 5.5) and G preserves sifted colimits, the above natural isomorphism implies that  $L(Y_{\mathcal{T}_1}(X))$  is perfectly presentable. By 5.14,  $L(Y_{\mathcal{T}_1}(X))$  is a retract of a representable algebra and, since  $\mathcal{T}_2$  is idempotent-complete,  $L(Y_{\mathcal{T}_1}(X))$  is itself a representable algebra (see 8.3.3). This means that there exists an essentially unique object in  $\mathcal{T}_2$ , say FX, such that  $L(Y_{\mathcal{T}_1}(X)) \simeq Y_{\mathcal{T}_2}(FX)$ . In this way we get a map on objects,  $F: \operatorname{obj} \mathcal{T}_1 \to \operatorname{obj} \mathcal{T}_2$ , which, by the Yoneda Lemma, extends to a functor  $F: \mathcal{T}_1^{op} \to \mathcal{T}_2^{op}$  making the above square commutative up to natural isomorphism. F preserves finite coproducts because  $Y_{\mathcal{T}_1}$  preserves them by 1.13,  $Y_{\mathcal{T}_2}$  reflects finite coproducts, and L preserves them. It remains to prove that

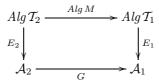

#### CHAPTER 9. ALGEBRAIC FUNCTORS

 $G \simeq Alg M$ , where  $M = F^{op}: \mathcal{T}_1 \to \mathcal{T}_2$ . Or, equivalently, that  $L \simeq M^*$  in the notation of 9.3. But this follows from the essential commutativity of the above square and the last part of 9.3. This proves that  $Alg_{\mathcal{T}_1,\mathcal{T}_2}$  is essentially surjective.

9.16 Corollary. A functor between algebraic categories

$$G: \mathcal{A}_2 \to \mathcal{A}_1$$

is algebraic if and only if it is induced by a morphism of theories. That is: there exists a morphism of the corresponding canonical algebraic theories  $M: \mathcal{T}_1 \to \mathcal{T}_2$ and two equivalence functors  $E_1: Alg \mathcal{T}_1 \to \mathcal{A}_1$  and  $E_2: Alg \mathcal{T}_2 \to \mathcal{A}_2$  such that the square

commutes up to natural isomorphism.

In fact, given G, the proof of 9.15 yields  $G \simeq Alg M$  with the desired property. The converse implication is clear.

**9.17 Remark.** The category *Set* is a kind of *dualizing object* for the biequivalence  $Alg: Th_c^{op} \rightarrow ALG:$ 

(1) Forgetting size considerations (an algebraic theory is by definition a small category) we have  $AlgT = Th(\mathcal{T}, Set)$  for every algebraic theory  $\mathcal{T}$ . (2) For every algebraic astronomy A there is an equivalence of extension

(2) For every algebraic category  $\mathcal{A}$  there is an equivalence of categories

$$\mathcal{A}_{pp}^{op} \simeq ALG(\mathcal{A}, Set)$$
.

Indeed, if  $A \in \mathcal{A}_{pp}^{op}$ , then  $G = \mathcal{A}(A, -): \mathcal{A} \to Set$  preserves limits and sifted colimits. Conversely, let  $G: \mathcal{A} \to Set$  be an algebraic functor and let L be a left adjoint of G (see 9.7). Then  $G \simeq \mathcal{A}(L1, -)$  (with 1 denoting a one-element set) and L1 is perfectly presentable because G preserves sifted colimits.

**9.18 Remark.** We conclude this chapter by mentioning the analogous Gabriel-Ulmer duality for locally finitely presentable categories. The proof is similar to that of 9.15. Whereas the morphisms of algebraic categories are the functors preserving limits and sifted colimits, the morphisms of locally finitely presentable categories are the functors preserving limits and filtered colimits. These are the 1-cells of the 2-category LFP, and the 2-cells are natural transformations. We also denote by LEX the 2-category of small categories with finite limits, finite limit preserving functors, and natural transformations. The 2-functor

$$Lex: LEX^{op} \to LFP$$

assigns to every small category  $\mathcal{T}$  with finite limits the category  $Lex\mathcal{T}$  (4.16) and it acts on 1-cells and 2-cells in the analogous way as  $Alg: Th^{op} \to ALG$ .

9.19 Theorem. The 2-categories LFP and LEX are dually biequivalent.

In fact,  $Lex: LEX^{op} \to LFP$  is a biequivalence. The converse construction associates to a locally finitely presentable category  $\mathcal{A}$  the small, finitely complete category  $\mathcal{A}_{fp}^{op}$  (6.26).

#### Historical Remarks for Chapter 9

Morphisms of algebraic theories and the resulting algebraic functors were (in the one-sorted case) introduced by F. W. Lawvere [60] and belong to the main contribution of his work. The characterization 9.7 of algebraic functors and the duality theorem 9.15 are contained in [5]. This is analogous to the Gabriel-Ulmer duality 9.19 for locally finitely presentable categories (see [45]). A general result can be found in [36].

2-categories have been introduced by C. Ehresmann in [41].

## Chapter 10

## **Birkhoff's Variety Theorem**

So far we have not treated one of the central concepts of algebra: equations. In the present chapter we prove the famous characterization of varieties of algebras, due to G. Birkhoff: varieties are precisely the full subcategories of  $Alg \mathcal{T}$  closed under

products,

subalgebras,

regular quotients,

and

directed unions.

The last item was not included in Birkhoff's formulation. The reason is that Birkhoff only considered one-sorted algebras, and for them directed unions follow from the other three items (see 11.34). For general algebraic categories directed unions cannot be omitted, see Example 10.23 below.

Classically, an equation is an expression u = v where u and v are terms (say, in n variables). We will see in 13.9 that such terms are morphisms from n to 1 in the theory of  $\Sigma$ -algebras. We can also consider k-tuples of classical equations as pairs of morphisms from n to k. The following concept generalizes this idea.

**10.1 Definition.** If  $\mathcal{T}$  is an algebraic theory, an *equation* in  $\mathcal{T}$  is a parallel pair  $u, v \colon s \rightrightarrows t$  of morphisms in  $\mathcal{T}$ . (Following algebraic tradition, we write u = v in place of (u, v).) An algebra  $A \colon \mathcal{T} \to Set$  satisfies the equation u = v if A(u) = A(v).

#### 10.2 Example.

1. In the theory  $\mathcal{T}_{ab}$  of abelian groups (1.6) recall that endomorphisms of 1 have the form [n] and correspond to the operations on abelian groups given by  $x \mapsto n \cdot x$ . Thus, the equation

$$[2] = [0]$$

is satisfied by precisely the groups with

$$x + x = 0$$

for all elements x.

2. Graphs whose only edges are loops are given, considering the theory in 1.11, by the equation

 $\tau=\sigma\,.$ 

**10.3 Remark.** Observe that if an algebra A satisfies the equation u = v, then it also satisfies all the equations of the form  $u \cdot x = v \cdot x$  and  $y \cdot u = y \cdot v$  for  $x: s' \to s$  and  $y: t \to t'$  in  $\mathcal{T}$ . Moreover, if the equations  $u_i = v_i, i = 1, \ldots, n$ , are satisfied by A for  $u_i, v_i: s \to t_i$ , then A also satisfies  $\langle u_i \rangle = \langle v_i \rangle$ , where

$$\langle u_i \rangle, \langle v_i \rangle \colon s \to t_1 \times \ldots \times t_n$$

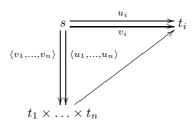

are the corresponding morphisms. For this reason, we will state the definition of variety using congruences as well as equations.

**10.4 Definition.** Let  $\mathcal{T}$  be an algebraic theory. A *congruence* on  $\mathcal{T}$  is a collection  $\sim$  of equivalence relations  $\sim_{s,t}$  on hom-sets  $\mathcal{T}(s,t)$ , where (s,t) ranges over pairs of objecs, which is stable under composition and finite products in the following sense:

1. If  $u \sim_{s,t} v$  and  $x \sim_{r,s} y$ , then  $u \cdot x \sim_{r,t} v \cdot y$ 

$$r \xrightarrow{x} y > s \xrightarrow{u} t$$

2. If  $u_i \sim_{s,t_i} v_i$  for i = 1, ..., n, then  $\langle u_1, ..., u_n \rangle \sim_{s,t} \langle v_1, ..., v_n \rangle$ , where  $t = t_1 \times ... \times t_n$ 

**10.5 Example.** Consider the theory  $\mathcal{T}_{mon}$  of monoids (3.10) whose morphisms from n to k are all k-tuples of words in  $n = \{0, 1, \ldots, n-1\}$ . The commutative law corresponds to the congruence  $\sim$  with  $\sim_{n,1}$  defined for words v and w by

 $w \sim_{n,1} v$  iff v can be obtained from w by a permutation of its letters.

The general equivalence  $\sim_{n,k}$  is defined by coordinates of the k-tuples of words.

**10.6 Example.** Let  $\mathcal{T}$  be an algebraic theory and let  $M: \mathcal{T} \to \mathcal{B}$  be a finite product preserving functor. The *kernel congruence* of M is denoted by  $\approx_M$ . That is, for all  $u, v \in \mathcal{T}(s, t)$  we put

$$u \approx_M v$$
 iff  $Mu = Mv$ 

This is obviously a congruence on  $\mathcal{T}$ . In particular, for every  $\mathcal{T}$ -algebra A we have a congruence  $\approx_A$ .

#### 10.7 Remark.

1. Congruences on a given algebraic theory  $\mathcal{T}$  are ordered in a canonical way: we write  $\sim \subseteq \sim'$  in case that for every pair s, t of objects of  $\mathcal{T}$  we have:

$$u \sim_{s,t} v$$
 implies  $u \sim'_{s,t} v$ 

2. It is easy to see that every (set theoretical) intersection of congruences is a congruence. Consequently, for every set E of equations there exists the smallest congruence  $\sim_E$  on  $\mathcal{T}$  containing E. We say that the congruence  $\sim_E$  is generated by the equations of E.

**10.8 Definition.** A full subcategory  $\mathcal{A}$  of  $Alg\mathcal{T}$  is called a *variety* if there exists a set of equations such that a  $\mathcal{T}$ -algebra lies in  $\mathcal{A}$  iff it satisfies all equations in that set.

#### 10.9 Remark.

- Varieties are also sometimes called equational classes of algebras, or equational categories. But we reserve this name for the special case of varieties of Σ-algebras treated in Chapters 13 (for one-sorted signatures) and 14 (for S-sorted ones).
- 2. We will use the name variety also in the loser sense of a category *equivalent* to a full subcategory of  $Alg \mathcal{T}$  specified by equations. Every time we use the word variety it will be clear whether the above definition is meant or the loser version.

#### 10.10 Example.

- 1. The abelian groups satisfying x + x = 0 form a variety in Ab.
- 2. All graphs whose edges are just loops form a variety in Graph.
- 3. Let us consider the category  $Set \times Set$  of two-sorted sets with sorts called, say, s and t. This has an algebraic theory  $\mathcal{T}_{\mathcal{C}}$  of all words in  $\{s, t\}$ , see 1.5. Consider the full subcategory  $\mathcal{A}$  of  $Set \times Set$  of all pairs  $A = (A_s, A_t)$  with either  $A_s = \emptyset$  or  $A_t$  has at most one element. This can be specified by the equation given by the parallel pair of projections

$$s t t \Longrightarrow t$$

**10.11 Remark.** Every variety is also specified by a congruence. More precisely, given a variety  $\mathcal{A}$  of  $Alg\mathcal{T}$ , let  $\sim$  be the congruence generated by the given set E of equations. A  $\mathcal{T}$ -algebra A lies in  $\mathcal{A}$  iff it satisfies all equations in  $\sim$ , that is, iff it fulfils:

$$u \sim v$$
 implies  $Au = Av$ 

In fact, if A satisfies all equations in E, then  $E \subseteq \approx_A$  and therefore  $\sim \subseteq \approx_A$ .

**10.12 Notation.** For every congruence  $\sim$  on an algebraic theory  $\mathcal{T}$  we denote by

$$T/\sim$$

the algebraic theory on the same objects and with morphisms given by the congruence classes of morphisms of  $\mathcal{T}$ :

$$(\mathcal{T}/\sim)(s,t) = \mathcal{T}(s,t)/\sim_{s,t}$$
.

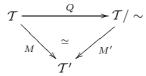

Composition and identity morphisms are inherited from  $\mathcal{T}$ ; more precisely, they are determined by the fact that we have a functor

$$Q\colon \mathcal{T} \to \mathcal{T}/\sim$$

which is the identity map on objects and which assigns to every morphism its congruence class.

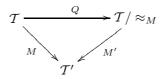

#### 10.13 Remark.

- 1. It is easy to verify that  $\mathcal{T}/\sim$  has finite products determined by those of  $\mathcal{T}$ , thus,  $\mathcal{T}/\sim$  is an algebraic theory and Q is a theory morphism. Moreover, the functor Q is full and surjective on objects.
- 2. A morphism of theories  $M \colon \mathcal{T} \to \mathcal{T}'$  factorizes through Q up to natural isomorphism

iff the congruence ~ is contained in the kernel congruence  $\approx_M$ . When this is the case, the factorization M' is essentially unique and it is a theory morphism. In fact, it is clear that if  $M' \cdot Q \simeq M$ , then  $\sim \subseteq \approx_M$ . For the converse define M' to be equal to M on objects, and put M'[f] = Mf on morphisms. Clearly,  $M' \cdot Q = M$ . From the fact that M preserves finite products and Q reflects them the desired properties of M' easily follow.

3. If in 2. we take ~ equal to the congruence  $\approx_M$ , then the factorization M'

February 1, 2010

88

is faithful. Therefore, M is full and essentially surjective iff M' is an equivalence of categories.

**10.14 Proposition.** Let ~ be a congruence on an algebraic theory  $\mathcal{T}$  and let  $Q: \mathcal{T} \to \mathcal{T} / \sim$  be the corresponding quotient. The functor

$$Alg Q: Alg (\mathcal{T}/\sim) \to Alg \mathcal{T}$$

is full and faithful.

#### Proof.

(1) Clearly, AlqQ is faithful because Q is surjective.

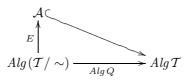

(2) Consider objects  $A, B \in Alg\mathcal{T}/\sim$  and a morphism  $\beta: A \cdot Q \to B \cdot Q$ , that is, a collection  $\beta_t: At \to Bt$  of homomorphisms natural in t ranging through  $\mathcal{T}$ . Then the same collection is natural in t ranging through  $\mathcal{T}/\sim$ , thus,  $\beta: A \to B$ is a morphism of  $Alg(\mathcal{T}/\sim)$ . Clearly, AlgQ takes this morphism to the original one.

**10.15 Corollary.** Every variety is an algebraic category.

More detailed: let  $\sim$  be a congruence on an algebraic theory  $\mathcal{T}$ , and let  $\mathcal{A}$  be the full subcategory of  $Alg\mathcal{T}$  specified by  $\sim$ . There exists an isomorphism of categories

$$E: Alg(\mathcal{T}/\sim) \to \mathcal{A}$$

such that the triangle

commutes. In fact, for every  $(\mathcal{T}/\sim)$ -algebra B, given  $u \sim v$ , then B(Qu) = B[u] = B[v] = B(Qv). This implies that AlgQ factorizes through the inclusion of  $\mathcal{A}$  in  $Alg\mathcal{T}$ . Moreover, if A lies in  $\mathcal{A}$ , then A = (AlgQ)(B) where B is the  $(\mathcal{T}/\sim)$ -algebra defined by B[u] = Au. This shows that the factorization  $E: Alg(\mathcal{T}/\sim) \to \mathcal{A}$  is bijective on objects. Since AlgQ is full and faithful (see 10.14), E is an isomorphism.

**10.16 Proposition.** Every variety  $\mathcal{A}$  of  $\mathcal{T}$ -algebras is closed in Alg $\mathcal{T}$  under

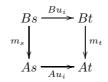

- (a) products: given a product  $B = \prod_{i \in I} A_i$  in  $Alg \mathcal{T}$  with all  $A_i$  in  $\mathcal{A}$ , then B also lies in  $\mathcal{A}$ ,
- (b) subalgebras: given a monomorphism  $m: B \to A$  in AlgT with A in A, then B also lies in A,
- (c) regular quotients: given a regular epimorphism  $e: A \to B$  in Alg  $\mathcal{T}$  with A in  $\mathcal{A}$ , then B also lies in  $\mathcal{A}$ ,

and

(d) sifted colimits: given a sifted colimit  $B = \operatorname{colim} A_i$  in  $\operatorname{Alg} \mathcal{T}$  with all  $A_i$  in  $\mathcal{A}$ , then B also lies in  $\mathcal{A}$ .

**Proof.** Following 10.15, the inclusion functor  $\mathcal{A} \to Alg \mathcal{T}$  is naturally isomorphic to Alg Q, which preserves limits and sifted colimits by 9.3. This proves (a) and (d).

(b) Let  $m: B \to A$  be a monomorphism with A in  $\mathcal{A}$ . We prove that B is in  $\mathcal{A}$  by verifying that every equation  $u_1, u_2: s \rightrightarrows t$  that A satisfies is also satisfied by B. We know from 1.23.2 that the component  $m_t: Bt \to At$  is a monomorphism. From  $A(u_1) = A(u_2)$  and the commutativity of the squares

we conclude  $Bu_1 = Bu_2$ .

(c) Let  $e: A \to B$  be a regular epimorphism with A in  $\mathcal{A}$ . To prove that B lies in  $\mathcal{A}$ , observe that a kernel pair  $k_1, k_2: N(e) \rightrightarrows A$  of e yields a subobject of  $A \times A \in \mathcal{A}$ , thus N(e) lies in  $\mathcal{A}$ . by (a) and (b). And since the pair  $k_1, k_2$  is reflexive and e is its coequalizer, B is a sifted colimit (3.2) of a diagram in  $\mathcal{A}$ , thus  $B \in \mathcal{A}$ .

**10.17 Corollary.** Every variety  $\mathcal{A}$  of  $\mathcal{T}$ -algebras is closed in Alg $\mathcal{T}$  under limits and sifted colimits.

**10.18 Example.** Not every full subcategory of an algebraic category  $Alg\mathcal{T}$  closed under limits and sifted colimits is a variety. Consider the free completion  $\mathcal{T}'$  of  $\mathcal{T}$  under finite products (1.14) and the finite product preserving extension  $M: \mathcal{T}' \to \mathcal{T}$  of the identity functor on  $\mathcal{T}$ . The induced functor AlgM is naturally isomorphic to the full inclusion  $Alg\mathcal{T} \to Alg\mathcal{T}' \simeq Set^{\mathcal{T}}$ . But  $Alg\mathcal{T}$  is usually not closed in  $Set^{\mathcal{T}}$  under subalgebras (in contrast to 10.16). As a concrete example, let  $\mathcal{T}$  be the category of finite sets and functions. The functor

$$A\colon \mathcal{T} \to Set \,, \ AX = X \times X \times X$$

is clearly an algebra for  $\mathcal{T}$ , but its subfunctor A' given by all triples in  $X \times X \times X$ in which at least two different coordinates have the same value is not an algebra for  $\mathcal{T}$ .

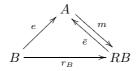

**10.19 Remark.** Following 10.13.3 and 10.14, the algebraic functor induced by a full and essentially surjective morphism of theories is full and faithful. The morphism  $M: \mathcal{T}' \to \mathcal{T}$  in 10.18 also demonstrates that the converse implication does not hold:  $Alg M: Alg \mathcal{T} \to Set^{\mathcal{T}}$  is full and faithful, but M is not full.

#### CHAPTER 10. BIRKHOFF'S VARIETY THEOREM

**10.20 Definition.** A full reflective subcategory  $\mathcal{A}$  of a category  $\mathcal{B}$  (see 0.9) is called *regular epireflective* if all reflections  $r_B \colon B \to RB$  are regular epimorphisms.

**10.21 Corollary.** Every variety of  $\mathcal{T}$ -algebras is a regular epireflective subcategory of  $Alg\mathcal{T}$  closed under regular quotients and directed unions.

**Proof.** We already know that the variety  $\mathcal{A}$  is closed in  $Alg\mathcal{T}$  under regular quotients and sifted colimits (10.16) and therefore under directed unions, which are a special case of sifted colimits (2.9). Moreover, following 10.15, the inclusion functor  $\mathcal{A} \to Alg\mathcal{T}$  is naturally isomorphic to AlgQ, which has a left adjoint (9.3). It remains to prove that for every  $\mathcal{T}$ -algebra B the reflection  $r_B \colon B \to RB$  is a regular epimorphism. Let  $r_B = m \cdot e$ 

be a regular factorization of  $r_B$ , see 3.7. By 10.16(b)  $A \in \mathcal{A}$ , thus there is a unique  $\bar{e}: RB \to A$  such that  $e = \bar{e} \cdot r_B$ . Since e is an epimorphism, we see that  $\bar{e} \cdot m = \mathrm{id}_A$ . Also  $m \cdot \bar{e} = \mathrm{id}_{RB}$  due to the universal property of  $r_B$ . Thus, m is an isomorphism and  $r_B$  a regular epimorphism.

**10.22 Birkhoff's Variety Theorem.** Let  $\mathcal{T}$  be an algebraic theory. A full subcategory  $\mathcal{A}$  of  $Alg\mathcal{T}$  is a variety if and only if it is closed in  $Alg\mathcal{T}$  under

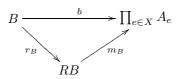

- (a) products,
- (b) subalgebras,
- (c) regular quotients,

and

(d) directed unions.

**Proof.** Every variety is closed under (a)-(d): see 10.16. Conversely, let  $\mathcal{A}$  be closed under (a)-(d).

(1) We first prove that  $\mathcal{A}$  is a regular epireflective subcategory. Let B be a  $\mathcal{T}$ -algebra. By 3.6 there exists a set of regular epimorphisms  $e: B \to A_e \ (e \in X)$  representing all regular quotients of B with codomain in  $\mathcal{A}$ . Denote by  $b: B \to \prod_{e \in X} A_e$  the induced morphism and let

be the regular factorization of b (see 3.7). The algebra RB lies in  $\mathcal{A}$  (because it is a subalgebra of a product of algebras in  $\mathcal{A}$ ) and  $r_B$  is the reflection of Bin  $\mathcal{A}$ . Indeed, for every morphism  $f: B \to A$  with A in  $\mathcal{A}$  we have a regular factorization

 $f = m \cdot e$  for some  $e \in X$ 

and since e factorizes through b, so does f.

(2) We will prove that  $\mathcal{A}$  is specified by the congruence  $\sim$  which is the intersection of the kernel congruences of all algebras in  $\mathcal{A}$ :

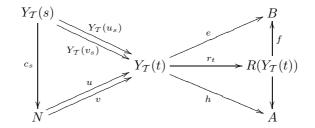

$$u_1 \sim_{s,t} u_2$$
 iff  $Au_1 = Au_2$  for all  $A \in \mathcal{A}$ .

This is indeed a congruence, see 10.6 and 10.7.2. It is our task to prove that every  $\mathcal{T}$ -algebra B such that  $\sim$  is contained in  $\approx_B$ , see 10.7, lies in  $\mathcal{A}$ .

(2a) Assume first that B is a regular quotient of a representable algebra  $Y_{\mathcal{T}}(t)$ . We thus have a regular epimorphism  $e: Y_{\mathcal{T}}(t) \to B$ . We know that the reflection morphism  $r_t: Y_{\mathcal{T}}(t) \to R(Y_{\mathcal{T}}(t))$  is a regular epimorphism, thus, it is a coequalizer

$$N \xrightarrow{u}_{v} Y_{\mathcal{T}}(t) \xrightarrow{r_t} R(Y_{\mathcal{T}}(t))$$

By 4.2 we can express N as a sifted colimit of representable algebras, denote the colimit cocone by  $c_s: Y_T(s) \to N$ . Using Yoneda Lemma, we see that for every s there exist morphisms  $u_s, v_s: t \rightrightarrows s$  representing  $u \cdot c_s$  and  $v \cdot c_s$ , respectively:

Moreover, we have  $u_s \sim_{t,s} v_s$  because every morphism  $h: Y_T(t) \to A$  with  $A \in \mathcal{A}$  factorizes through  $r_t$ , so that  $Y_T(u_s) \cdot h = Y_T(v_s) \cdot h$ , and it follows that  $Au_s = Av_s$ . By assumption on B, this implies  $Bu_s = Bv_s$ , and then  $e \cdot u \cdot c_s = e \cdot v \cdot c_s$ . The cocone  $c_s$  is jointly epimorphic, thus we have  $e \cdot u = e \cdot v$ . Since  $r_t$  is the coequalizer of u and v, there exists  $f: R(Y_T(t)) \to B$  such that  $f \cdot r_t = e$ . Finally, f is a regular epimorphism because e is, so that B, being a regular quotient of  $R(Y_T(t))$ , lies in  $\mathcal{A}$ .

(2b) Let *B* be arbitrary. Express *B* as a sifted colimit of representable algebras (4.2) and for each of the colimit morphisms  $\sigma_s \colon Y_T(s) \to B$  denote by  $B_s$  the image of  $\sigma_s$  which, by 3.7, is a subalgebra of *B*. Since *T* has finite products, the collection of these subalgebras of *B* is directed. Due to assumption (d) we only need to prove that every  $B_s$  lies in  $\mathcal{A}$ . This follows from (2a): we know that  $B_s$  is a regular quotient of a representable algebra, and  $B_s$  has the desired property: given  $u_1 \sim_{s,t} u_2$ , we have  $B(u_1) = B(u_2)$  and this implies  $B_s u_1 = B_s u_2$  since  $B_s$  is a subalgebra of *B*.

#### CHAPTER 10. BIRKHOFF'S VARIETY THEOREM

**10.23 Example.** The assumption of closure under directed unions cannot be omitted: consider the category  $Set^{\mathbb{N}}$  of  $\mathbb{N}$ -sorted sets and let  $\mathcal{A}$  be the full subcategory of all  $A = (A_n)_{n \in \mathbb{N}}$  such that either some  $A_n$  is empty or all  $A_n$ 's have precisely one element. This subcategory is clearly closed under products, subalgebras and regular quotients – we omit the easy verification. However, it is not a variety, not being closed under directed unions. In fact, every  $\mathbb{N}$ -sorted set  $A = (A_n)_{n \in \mathbb{N}}$  is a directed union of objects  $A^k$  of  $\mathcal{A}$ : put  $A^k = (A_0, \ldots, A_k, \emptyset, \emptyset, \ldots)$ .

**10.24 Corollary.** Let  $\mathcal{A}$  be a full subcategory of  $Alg\mathcal{T}$ . Then  $\mathcal{A}$  is a variety if and only if it is a regular epireflective subcategory closed under regular quotients and directed unions.

In fact, following 10.21 and 10.22, we only need to observe that every regular epireflective subcategory  $\mathcal{A}$  is closed in  $Alg\mathcal{T}$  under products (and this is obvious) and subalgebras: consider the diagram

$$\begin{array}{c} B \xrightarrow{m} A \\ r_B \downarrow & \downarrow r_A \\ RB \xrightarrow{Rm} RA \end{array}$$

where m is a monomorphism and A lies in A. Then  $r_A$  is an isomorphism and  $r_B$  is a monomorphism. But  $r_B$  is also a regular epimorphism, so that it is an isomorphism, and B lies in A.

**10.25 Example.** The category  $Ab_{tf}$  of torsion free abelian groups is a regular epireflective subcategory of Ab closed under filtered colimits. But this is not a variety in Ab because it is not closed under quotients. Indeed,  $Ab_{tf}$  is locally finitely presentable but not algebraic (it is not exact).

#### Historical Remarks for Chapter 10

The classical characterization of varieties of one-sorted algebras as HSP-classes is due to G. Birkhoff [25]; we present this version in 11.34.

For many-sorted algebras the concept of equation in 10.1 corresponds to the formulas

$$\forall x_1 \dots \forall x_n \ (t=s)$$

where t and s are terms of the same sort in (sorted) variables  $x_1, \ldots, x_n$ . Example 10.23 demonstrates that with respect to the above equations we need to add the closure under directed unions. Another approach is to admit infinitely many variables in the equations – that is, to work in the logic  $L_{\omega\infty}$  (admitting quantification over infinite sets) rather than in the finitary logic  $L_{\omega\omega}$ . In this logic directed unions can be omitted in Birkhoff's Variety Theorem. This is illustrated by Example 14.21 below (see also [12]).

Dropping in 10.24 the assumption of closure under regular quotients, one gets the so-called *quasivarieties*. Theories of quasivarieties have been studied by J. Adámek and H.-E. Porst in [7]. A survey on quasivarieties based on free completions is presented in [78].

### CHAPTER 10. BIRKHOFF'S VARIETY THEOREM

# Part II: Concrete algebraic categories

"The most elegant treatment of clones is given by F. W. Lawvere and J. Bénabou using categories."

G. Grätzer, Universal Algebra, Springer-Verlag 2008.

## . PART II: CONCRETE ALGEBRAIC CATEGORIES

## Chapter 11

## One-sorted algebraic categories

Classical algebraic categories, such as groups, modules, boolean algebras, etc. are not only abstract categories: their objects are sets with a structure, and their morphisms are functions preserving the structure. Thus, they are concrete categories over *Set* (see 0.18), which means that a "forgetful" functor into *Set* is given. Also, these classical algebraic categories have theories generated by a single object X in the sense that all objects of the theory are finite powers  $X^n$  of X. (Consider the free group on one generator X : in the theory of groups, which is the dual of the category of finitely generated free groups, every object is a power of X.) In order to formalize this idea, we study in this chapter one-sorted algebraic categories. In Chapter 14 we will deal with the more general notion of S-sorted algebraic categories, for which the forgetful functor into a power of *Set* is considered rather than into *Set*.

## 11.1 Example. The theory

 $\mathcal{N}$ 

of sets (see 1.4), which is the full subcategory of  $Set^{op}$  on natural numbers  $n = \{0, \ldots, n-1\}$ , is a "prototype" one-sorted theory: every object n is the product of n copies of 1. Moreover, the n injections in Set

$$\pi_i^n : 1 \to n , \ 0 \mapsto i \ (i = 0, \dots, n-1)$$

yield a canonical choice of projections  $\pi_i^n \colon n \to 1$  in  $\mathcal{N}$  which present n as  $1^n$ .

#### 11.2 Remark.

1. If an algebraic theory  $\mathcal{T}$  has all objects finite powers of an object X, we obtain a theory morphism  $T: \mathcal{N} \to \mathcal{T}$  as follows: for every n choose an n-th power of X with projections  $p_i^n: X^n \to X$  for  $i = 0, \ldots, n-1$ . Then T is uniquely determined by

 $Tn = X^n \text{ and } T\pi^n_i = p^n_i \text{ for all } i < n \text{ in } \mathbb{N} \,.$ 

2. Conversely, every theory morphism  $T: \mathcal{N} \to \mathcal{T}$  represents an object and a choice of projections of all of its finite powers: put X = T1 and  $p_i^n = T\pi_i^n: X^n \to X$  for all i < n.

This leads us to the following

## 11.3 Definition.

- 1. A one-sorted algebraic theory is a pair  $(\mathcal{T}, T)$  where  $\mathcal{T}$  is an algebraic theory whose objects are the natural numbers, and  $T: \mathcal{N} \to \mathcal{T}$  is a theory morphism which is the identity map on objects.
- 2. A morphism of one-sorted algebraic theories  $M: (\mathcal{T}_1, T_1) \to (\mathcal{T}_2, T_2)$  is a functor  $M: \mathcal{T}_1 \to \mathcal{T}_2$  such that  $M \cdot T_1 = T_2$

### 11.4 Remark.

- 1. We have not requested that morphisms of one sorted theories preserve finite products. In fact, this simply follows from the equation  $M \cdot T_1 = T_2$ . Observe that due to that equation M is the identity map on objects. Since, moreover, M takes the projections  $T_1 \pi_i^n$  to the projections  $T_2 \pi_i^n$ , it clearly preserves finite powers, thus, finite products.
- 2. The reason why one-sorted theories are requested to be equipped with a theory morphism from  $\mathcal{N}$  is that in this way the category of one-sorted theories and the category of finitary monads on *Set* are equivalent, as proved in A.38. (And, by the way, this is the original definition by Lawvere from 1963.)
- 3. There is an obvious non-strict version of morphism of one-sorted theories, where the equality above is weaken to a natural isomorphism between  $M \cdot T_1$  and  $T_2$ . See Appendix C for this approach.

**11.5 Example.** Recall the theory  $\mathcal{T}_{ab}$  of abelian groups whose objects are natural numbers and morphisms are matrices (see 1.6). It can be canonically considered as a one-sorted theory if we define  $T_{ab}: \mathcal{N} \to \mathcal{T}_{ab}$  as the identity map on objects, and assign to  $\pi_i^n: n \to 1$  the one-row matrix with *i*-th entry 1 and all other entries 0.

**11.6 Remark.** Given a one-sorted theory  $(\mathcal{T}, T)$ , the functor T does not influence the concept of algebra: the category  $Alg\mathcal{T}$  thus consists, again, of all functors  $A: \mathcal{T} \to Set$  preserving finite products. However, the presence of T

makes the category of algebras concrete over Set (see 0.18). Assuming that we identify Set and  $Alg \mathcal{N}$ , the forgetful functor is simply

$$AlgT: AlgT \to Set$$

(see 9.2), which is faithful by 11.8. More precisely, this forgetful functor takes an algebra  $A: \mathcal{T} \to Set$  to the set A1, and a homomorphism  $h: A \to B$  to the component  $h_1: A1 \to B1$ .

**11.7 Example.** For the one-sorted theory  $(\mathcal{T}_{ab}, T_{ab})$  of abelian groups the category  $Alg \mathcal{T}_{ab}$  is equivalent to Ab. (But it is not isomorphic to Ab: this is caused by the fact that algebras for  $\mathcal{T}_{ab}$  are not required to preserve products strictly. Consequently, there exist many algebras that are naturally isomorphic to algebras of the form  $\hat{G}$  (see 1.6) but are not equal to any of those.) The forgetful functor assigns, for every group G, to  $\hat{G}$  the underlying set of G. Observe that, unlike in Ab, there exist isomorphisms  $f: A \to B$  in  $Alg \mathcal{T}_{ab}$  for which A1 = B1 and  $f_1 = \text{id but still } A \neq B$ . In fact, given a group G we usually have many algebras  $B \neq \hat{G}$  naturally isomorphic to  $\hat{G}$  such that the component of the natural isomorphism at 1 is the identity. In other words,  $Alg \mathcal{T}_{ab}$  is not amnestic (see 13.16).

**11.8 Proposition.** Let  $(\mathcal{T}, T)$  be a one-sorted algebraic theory. The forgetful functor  $AlgT: Alg\mathcal{T} \rightarrow Set$  is algebraic, faithful and conservative.

**Proof.** AlgT is algebraic by 9.3. Let  $f: A \to B$  be a homomorphism of  $\mathcal{T}$ -algebras. Because of the naturality of f, the following square commutes

$$\begin{array}{ccc} AT^n & \xrightarrow{f_{T^n}} BT^n \\ \simeq & & \downarrow \simeq \\ (AT)^n & \xrightarrow{f_T^n} (BT)^n \end{array}$$

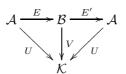

It is now obvious that AlgT is faithful and conservative.

**11.9 Corollary.** Let  $(\mathcal{T}, T)$  be a one-sorted algebraic theory. The forgetful functor preserves and reflects limits, sifted colimits, monomorphisms and regular epimorphisms.

**11.10 Remark.** For every  $\mathcal{T}$ -algebra A and every subset X of its underlying set A1 there exists the least subalgebra  $\overline{X}$  of A such that  $\overline{X}1$  contains X ( $\overline{X}$  is called the *subalgebra generated* by X). In fact, consider the intersection of all subalgebras of A containing X.

11.11 Remark. The concept of algebraic category in Chapter 1 used equivalences of categories. For one-sorted algebraic theories we need more: the equivalence functor must be concrete. This is, in fact, not enough because a quasiinverse of a concrete functor is in general not concrete. We are going to require that the equivalence functor admits a quasi-inverse which is concrete.

**11.12 Definition.** Given concrete categories  $U: \mathcal{A} \to \mathcal{K}$  and  $V: \mathcal{B} \to \mathcal{K}$  over  $\mathcal{K}$ , by a *concrete equivalence* between them we mean a pair of concrete functors

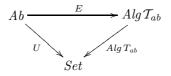

such that both  $E \cdot E'$  and  $E' \cdot E$  are naturally isomorphic to the identity functors. We then say that  $(\mathcal{A}, U)$  and  $(\mathcal{B}, V)$  are *concretely equivalent*.

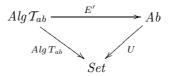

**11.13 Definition.** A one-sorted algebraic category is a concrete category over Set which is concretely equivalent to  $AlgT: AlgT \rightarrow Set$  for a one-sorted algebraic theory  $(\mathcal{T}, T)$ .

**11.14 Remark.** A non-strict version of one-sorted algebraic categories is treated in Appendix C.

**11.15 Example.** The category Ab with its canonical forgetful functor is a onesorted algebraic category. In fact, it is concretely equivalent to the category of algebras for  $(\mathcal{T}_{ab}, \mathcal{T}_{ab})$ : the functor

which to every group G assigns the algebra  $\widehat{G}: \mathcal{T}_{ab} \to Set$  of Example 1.6 is concrete. And we have the concrete functor

which to every algebra  $A: \mathcal{T}_{ab} \to Set$  assigns the group G with  $A \simeq \widehat{G}$  from 1.6. It is easy to verify that both  $E \cdot E'$  and  $E' \cdot E$  are naturally isomorphic to the identity functors.

**11.16 Remark.** Given a concrete category  $(\mathcal{A}, U)$ , all subcategories of  $\mathcal{A}$  are considered to be concrete by using the domain restriction of U.

**11.17 Proposition.** Every variety of  $\mathcal{T}$ -algebras for a one-sorted theory  $(\mathcal{T}, T)$  is a one-sorted algebraic category.

**Proof.** Let ~ be a congruence on  $\mathcal{T}$  and let  $Q: \mathcal{T} \to \mathcal{T}/\sim$  be the corresponding quotient functor. Since Q preserves finite products,  $(\mathcal{T}/\sim, Q \cdot T)$  is

a one-sorted theory. Consider the full subcategory  $\mathcal{A}$  of  $Alg \mathcal{T}$  specified by  $\sim$ . The equivalence

$$E: Alg(\mathcal{T}/\sim) \to \mathcal{A}$$

constructed in 10.15 is a concrete functor (because AlgQ is concrete). Moreover, E is an isomorphism (not just an equivalence) because it is bijective on objects. Thus, the inverse functor  $E^{-1}: \mathcal{A} \to Alg(\mathcal{T}/\sim)$  is concrete.

**11.18 Example.** The category Graph of graphs is algebraic, but not one-sorted algebraic. In fact, a terminal object in Graph is the graph with one vertex and one edge, and it has a proper subobject given by the graph G with one vertex and no edge. Observe that G is neither terminal nor initial in Graph. Now use the following

**11.19 Lemma.** In a one-sorted algebraic category a terminal object A has no nontrivial subobjects: for every subobject  $m: B \to A$  either B is an initial object or a terminal one.

**Proof.** Given a one-sorted algebraic theory  $(\mathcal{T}, T)$ , denote by A a terminal object of  $Alg\mathcal{T}$  and by I the initial one. Since  $Alg\mathcal{T}: Alg\mathcal{T} \to Set$  preserves limits (11.9), B(1) is a subobject of A1 = 1. If  $B1 \simeq 1$ , then  $m_1$  is an isomorphism and thus m is an isomorphism (since  $Alg\mathcal{T}$  is conservative). If  $B1 = \emptyset$ , consider the unique monomorphism  $a: I \to B$  and the induced map  $a_1: I1 \to B1 = \emptyset$ . Such a map is necessarily an isomorphism, and thus so is a. It is easy to see that concrete equivalences preserve the above property of terminal objects.  $\Box$ 

**11.20 Example.** Even though the category of graphs is not a one-sorted algebraic category, the category RGraph of reflexive graphs is. Here the objects are directed graphs

$$G_e \xrightarrow[\sigma]{\tau} G_v$$

together with a map  $d: G_v \to G_e$  such that  $\tau \cdot d = \mathrm{id}_{G_v} = \sigma \cdot d$ . A morphism from  $(G_e, G_v, \tau, \sigma, d)$  to  $(G'_e, G'_v, \tau', \sigma', d')$  is a graph homomorphism

$$(h_e \colon G_e \to G'_e, h_v \colon G_v \to G'_v)$$

such that  $h_e \cdot d = d' \cdot h_v$ . We consider this category as concrete over *Set* by  $U(G_e, G_v, \tau, \sigma, d) = G_e$ .

In fact, the category RGraph is concretely equivalent to the following onesorted algebraic category  $\mathcal{A}$ : an object of  $\mathcal{A}$  is a set  $G_e$  equipped with two maps

$$G_e \xrightarrow{t}_{s} G_e$$

such that  $s \cdot t = t$  and  $t \cdot s = s$ . A morphism from  $(G_e, t, s)$  to  $(G'_e, t', s')$  is a map  $h_e \colon G_e \to G'_e$  such that  $h_e \cdot t = t' \cdot h_e$  and  $h_e \cdot s = s' \cdot h_e$ .

1. Define  $E: RGraph \to \mathcal{A}$  by assigning to a reflexive graph  $(G_e, G_v, \tau, \sigma, d)$  the object  $(G_e, t, s)$  of  $\mathcal{A}$  by defining  $t = d \cdot \tau$  and  $s = d \cdot \sigma$ . This is a concrete

functor.

2. Define  $E': \mathcal{A} \to RGraph$  by assigning to an object  $(G_e, t, s)$  in  $\mathcal{A}$  the reflexive graph  $(G_e, G_v, \tau, \sigma, d)$  by taking as  $d: G_v \to G_e$  a joint equalizer of

$$G_e \xrightarrow[s]{t} G_e$$

This yields the canonical factorizations  $\tau: G_e \to G_v$  of t through d, and  $\sigma: G_e \to G_v$  of s through d (such factorizations exist because  $t = s \cdot t = t \cdot s \cdot t = t \cdot t$  and analogously for s). The rest of the definition of E' is straightforward. Again, E' is a concrete functor.

3. The verification that  $E \cdot E'$  and  $E' \cdot E$  are naturally isomorphic to the identity functors is easy.

- 11.21 Remark. Let  $(\mathcal{T}, T)$  be a one-sorted theory.
  - 1. The forgetful functor  $AlgT: AlgT \to Set$  has a left adjoint. In fact, due to 4.11 applied to  $Y_{\mathcal{N}}: \mathcal{N}^{op} \to Set$  we can choose a left adjoint

$$F_T \colon Set \to Alg \mathcal{T}$$

in such a way that the square

$$\begin{array}{c|c} \mathcal{N}^{op} \xrightarrow{T^{op}} \mathcal{T}^{op} \\ Y_{\mathcal{N}} & & \downarrow \\ Y_{\mathcal{T}} & & \downarrow \\ Set \xrightarrow{F_{T}} Alg \mathcal{T} \end{array}$$

commutes. Thus, for every natural number n,

(a) 
$$F_T(n) = \mathcal{T}(n, -)$$

and

- (b)  $F_T(\pi_i^n) = -\cdot T\pi_i^n$  for all i = 0, ..., n 1.
- 2. The naturality square for  $\eta$ : Id  $\rightarrow AlgT \cdot F_T$  applied to  $\pi_i^n$  yields the commutativity of

$$\begin{array}{c|c} 1 & \xrightarrow{\eta_1} \mathcal{T}(1,1) \\ \pi_i^n & & \downarrow \\ n & \xrightarrow{\eta_n} \mathcal{T}(n,1) \end{array}$$

that is

$$\eta_n(i) = T\pi_i^n$$
 for all  $i = 0, \ldots, n-1$ 

(recall that  $\pi_i^n$  is the inclusion of *i*).

3. Since  $F_T$  preserves coproducts,  $F_T X = \coprod_X Y_T(1)$  for every set X.

#### CHAPTER 11. ONE-SORTED ALGEBRAIC CATEGORIES

4.  $\mathcal{T}$ -algebras of the form  $F_T X$ , for X a set, are called *free algebras*. If X is finite, they are called *finitely generated free algebras*.

**11.22 Corollary.** Let  $(\mathcal{T}, T)$  be a one-sorted theory.  $\mathcal{T}^{op}$  is equivalent to the full subcategory of  $Alg\mathcal{T}$  of finitely generated free algebras.

Indeed by Yoneda Lemma  $\mathcal{T}(n,k) \simeq Alg \mathcal{T}(Y_{\mathcal{T}}(k),Y_{\mathcal{T}}(n)) = Alg \mathcal{T}(F_T(k),F_T(n)).$ 

**11.23 Remark.** Every object of a category with finite coproducts defines an algebraic theory  $\mathcal{T}(A)$  for which we need to fix coproduct injections

 $p_i^n \colon A \to nA = A + \ldots + A$  (*n* summands).

The objects of  $\mathcal{T}(A)$  are natural numbers, and morphisms from n to k are the morphisms of  $\mathcal{A}$  from  $kA = A + \ldots + A$  to nA. Then  $T: \mathcal{N} \to \mathcal{T}(A)$  is defined by  $T\pi_i^n = p_i^n$ . Observe that  $\mathcal{T}(A)$  is equivalent to the full subcategory of  $\mathcal{A}^{op}$  on all finite copowers of A under the equivalence functor  $n \mapsto nA$ . The corresponding category of  $\mathcal{T}(A)$ -algebras can be equivalent to  $\mathcal{A}$ , as we have seen in the example  $\mathcal{A} = Ab$  and  $A = \mathbb{Z}$ . (In fact, if  $\mathcal{A} = Alg\mathcal{T}$  for a one-sorted algebraic theory  $(\mathcal{T}, T)$  and A = T1, then  $\mathcal{A}$  is always equivalent to  $Alg\mathcal{T}(A)$ .) These theories  $\mathcal{T}(A)$  are often seen as the "natural" algebraic theories in classical algebra (e.g. for  $\mathcal{A} =$  groups, lattices, monoids, etc.).

**11.24 Remark.** Extending 11.21, for every one-sorted algebraic category  $(\mathcal{A}, U)$  with a left adjoint  $F \dashv U$  a one-sorted theory can be constructed from the full subcategory of  $\mathcal{A}^{op}$  on the objects  $F\{x_0, \ldots, x_{n-1}\}$ . Here a set of "standard variables"  $x_0, x_1, x_2, \ldots$  is assumed. In fact, the *n* injections

$$\{x_0\} \to \{x_0, \dots, x_{n-1}\}, x_0 \mapsto x_i$$

define *n* morphisms  $p_i^n \colon F\{x_0, \ldots, x_{n-1}\} \to F\{x_0\}$  in  $\mathcal{A}^{op}$ . Let  $\mathcal{T}$  be the category whose objects are the natural numbers and whose morphisms are

$$\mathcal{T}(n,k) = \mathcal{A}(F\{x_0,\ldots,x_{k-1}\},F\{x_0,\ldots,x_{n-1}\}).$$

The composition in  $\mathcal{T}$  is inherited from  $\mathcal{A}^{op}$ , and so are the identity morphisms. The functor  $T: \mathcal{N} \to \mathcal{T}$  is determined by the above choice of morphisms  $p_i^n$  for all  $i \leq n$ .

**11.25 Example.** For the one-sorted theory  $(\mathcal{T}_{ab}, T_{ab})$  (11.5) the induced adjunction  $F_{T_{ab}} \dashv Alg T_{ab}$  is, up to concrete equivalence, the usual adjunction given by free abelian groups.

Using free algebras we can restate some facts from Chapter 5:

**11.26 Proposition.** Let  $(\mathcal{T}, T)$  be a one-sorted algebraic theory.

- 1. Free algebras are precisely the coproducts of representable algebras.
- 2. Every algebra is a regular quotient of a free algebra.

3. Regular projectives are precisely the retracts of free algebras.

**Proof.** 1: Following 11.21, every free algebra is a coproduct of representable algebras. Conversely, every representable algebra is free by 11.21. Thus, every coproduct of representable algebra is free because  $F_T$  preserves coproducts. 2: Following 4.2, every algebra is a regular quotient of a coproduct of representable algebras and then, by 1, it is a regular quotient of a free algebra. 3: This follows from 1. and 5.14.2.

**11.27 Remark.** We have used "finitely generated" in two different situations above: for objects of a category, see 5.21, and as a denotation of  $F_T X$  with X finite. The following proposition demonstrates that there is no conflict. Note, however, that a finitely generated free algebra can, in principle, coincide with a non-finitely generated one. In fact, in the variety of algebras satisfying, for a pair x, y of distinct variables, the equation x = y, all algebras are isomorphic.

**11.28 Proposition.** Let  $(\mathcal{T}, T)$  be a one-sorted algebraic theory.

- 1. Finitely generated free algebras are precisely the representable algebras. These are precisely the free algebras which are finitely generated (in the sense of Definition 5.21).
- 2. Perfectly presentable algebras are precisely the retracts of finitely generated free algebras.
- 3. Finitely presentable algebras are precisely the coequalizers of (reflexive) pairs of morphisms between finitely generated free algebras.

**Proof.** 1. follows from 11.21 and the observation that whenever the object  $F_T X$  is finitely generated then it is isomorphic to  $F_T X'$  for some finite set X'. In fact, the set X is the directed union of its nonempty finite subsets X'. Since  $F_T$  is a left adjoint and directed unions are directed colimits in *Set*, we see that  $F_T X$  is a directed colimit with the colimit cocone formed by all Fi, where  $i: X' \to X$  are the inclusion maps. Moreover, since each i is a split monomorphism in *Set*,  $F_T X$  is the directed union of the finitely generated free algebras  $F_T X'$ . Since  $F_T X$  is finitely generated, there exists a finite nonempty subset  $i: X' \to X$  and a homomorphism  $f: F_T X \to F_T X'$  such that  $F_T i \cdot f = id_{F_T X}$ . Thus  $F_T i: F_T X' \to F_T X$ , being a monomorphism and a split epimorphism, is an isomorphism.

2. follows from 1. and 5.14.1, and 3. follows from 1. and 5.17.

**11.29 Remark.** Let  $(\mathcal{T}, T)$  be a one-sorted algebraic theory and X a subset of the underlying set A1 of a  $\mathcal{T}$ -algebra A. The subalgebra of A generated by X (see 11.9) is a regular quotient of the free algebra  $F_T X$ . Indeed, consider the homomorphisms  $\overline{i}_X : F_T X \to A$  corresponding to the inclusion  $i_X : X \to A1$ . Then  $\overline{i}_X(F_T X)$  is a subalgebra of A because the forgetful functor preserves regular factorizations. This is obviously the least subalgebra of A containing X (use diagonal fill-in, see 0.16) and the codomain restriction of  $\overline{i}_X$  is a regular quotient.

February 1, 2010

104

**11.30 Proposition.** Let  $(\mathcal{T}, T)$  be a one-sorted algebraic theory and A a  $\mathcal{T}$ -algebra. The following conditions are equivalent:

- 1. A is finitely generated (see 5.21),
- 2. A is a regular quotient of a finitely generated free algebra,

and

3. there exists a finite subset X of A1 not contained in any proper subalgebra of A.

**Proof.** The equivalence between 1. and 2. follows from 5.21 and 11.18.1.  $1 \Rightarrow 3$ : Let A be a finitely generated object of  $Alg\mathcal{T}$ . Form a diagram in  $Alg\mathcal{T}$  indexed by the poset of all finite subsets of A1 by assigning to every such  $X \subseteq A1$  the subalgebra  $\overline{X}$  of A generated by X (see 11.10). Given finite subsets X and Y with  $X \subseteq Y \subseteq A1$ , the connecting map  $\overline{X} \to \overline{Y}$  is the inclusion map. Then the inclusion homomorphisms  $i_X : \overline{X} \to A$  form a colimit cocone of this directed diagram. Since the functor  $Alg\mathcal{T}(A, -)$  preserves this colimit, for  $id_A \in Alg\mathcal{T}(A, A)$  there exists a finite set X such that  $id_A$  lies in the image of  $i_X$  – but this proves  $\overline{X} = A$ .

 $3 \Rightarrow 2$ : If  $A = \overline{X}$  for a finite subset X of A1, then by 11.19 A is a regular quotient of the finitely generated free algebra  $F_T X$ .

## 11.31 Remark.

- 1. Recall the notion of an equivalence relation on an object A in a category from 3.12. If the category is  $Alg \mathcal{T}$ , following the terminology of general algebra in 11.32 and 11.33 we speak about *congruence on the algebra* A (instead of equivalence). This is a slight abuse of terminology since congruences were previously used for the theory  $\mathcal{T}$  itself.
- 2. Similarly to 11.10, for every  $\mathcal{T}$ -algebra A and every subset X of  $A1 \times A1$  there exists the least congruence on A whose underlying set contains X. Such a congruence is called the *congruence generated by* X.
- 3. The *finitely generated congruences* are those generated by finite subsets of  $A1 \times A1$ .
- **11.32 Lemma.** Let  $(\mathcal{T}, T)$  be a one-sorted algebraic theory. Given

$$F_T X \xrightarrow[v]{u} B$$

in Alg  $\mathcal{T}$ , the congruence on B generated by the image of  $\langle u, v \rangle$  coincides with that generated by the image of  $\langle u_1 \cdot \eta_X, v_1 \cdot \eta_X \rangle$ , where  $\eta_X \colon X \to (F_T X)(1)$  is the unit of the adjunction  $F_T \dashv Alg T$ .

**Proof.** Let *R* be the congruence by the image of  $\langle u, v \rangle$  and *S* that generated by the image of  $\langle u_1 \cdot \eta_X, v_1 \cdot \eta_X \rangle$ . To check the inclusion  $R \subseteq S$  use the universal property of  $\eta_X$  and the diagonal fill-in (cf. 0.16). The other inclusion is obvious.

**11.33 Corollary.** Let  $(\mathcal{T}, T)$  be a one-sorted algebraic theory. A  $\mathcal{T}$ -algebra A is finitely presentable if and only if there exists a coequalizer of the form

$$R \xrightarrow[r_2]{r_1} F_T Y \xrightarrow{c} A$$

with Y a finite set and R a finitely generated congruence on  $F_TY$ .

In fact, this follows from 11.28 and 11.32 by taking  $B = F_T Y$  with X and Y finite sets.

As announced at the beginning of Chapter 10, we are going to prove that condition (d) in Birkhoff's Variety Theorem 10.22 can be avoided when the theory is one-sorted.

**11.34 Proposition.** Let  $(\mathcal{T}, T)$  be a one-sorted algebraic theory. If a full subcategory  $\mathcal{A}$  of  $Alg\mathcal{T}$  is closed under products, subalgebras, and regular quotients, then it is a variety.

**Proof.** By 10.22 all we need is proving that  $\mathcal{A}$  is closed under directed unions. Let  $A = \bigcup_{i \in I} A_i$  be a directed union of algebras in  $\mathcal{A}$ . Since the forgetful functor AlgT preserves directed unions,  $A1 = \bigcup_{i \in I} (A_i 1)$ .

(1) If  $A1 = \emptyset$ , then A is a subalgebra of any  $\mathcal{T}$ -algebra. Since  $\mathcal{A}$  is nonempty (being closed in  $Alg\mathcal{T}$  under products), this proves that A is in  $\mathcal{A}$ .

(2) If  $A1 \neq \emptyset$ , we can choose  $i_0 \in I$  such that  $A_{i_0} 1 \neq \emptyset$ . The product  $\prod_{i \geq i_0} A_i$ lies in  $\mathcal{A}$ . It assigns to  $n \in \mathcal{N}$  the set of all tuples  $(x_i)_{i \geq i_0}$  with  $x_i \in A_i n$ ; we call the tuple stable if there exists  $j \geq i_0$  such that  $x_i = x_j$  for all  $i \geq j$  (this makes sense because if  $j \leq i$  then  $A_j n \subseteq A_i n$ ) and we call  $x_j$  the stabilizer of the tuple. The stabilizer of a stable tuple is unique because I is directed. Define a subfunctor B of  $\prod_{i\geq i_0} A_i$  by assigning to every n the set of all stable tuples in  $\prod_{i\geq i_0} A_i n$ . It is clear that since each  $A_i$  preserves finite products so does B. Thus, B is a subalgebra of the product, which proves that B lies in  $\mathcal{A}$ . We have a natural transformation  $f: B \to A$  assigning to every stable tuple  $(x_i)_{i\geq i_0}$  its stabilizer. Our choice of  $i_0$  is such that  $f_1$  is surjective: for a given  $x \in A_1$ choose  $i_1 \in I$  such that  $x \in A_{i_1} 1$ ; since I is directed there exists  $j \in I$  with  $i_0, i_1 \leq j$  and we can construct a stable tuple with stabilizer x. Following 11.9, f is a regular epimorphism. This proves that A lies in  $\mathcal{A}$ .

Recall the algebraic duality of Chapter 9: if we restrict algebraic theories to the canonical ones, we obtain a contravariant biequivalence between the 2category of algebraic categories and the 2-category of algebraic theories. In the one-sorted case a better result is obtained, since we do not have to restrict the theories at all.

## 11.35 Definition.

1. The 2-category  $Th^1$  of one-sorted theories has

objects: one-sorted algebraic theories,

1-cells: morphisms of one-sorted algebraic theories,2-cells: natural transformations.

2. The 2-category  $ALG^1$  of one-sorted algebraic categories has

objects: one-sorted algebraic categories,

1-cells: concrete functors,

2-cells: natural transformations.

**11.36 Remark.** Every 1-cell in  $ALG^1$  is a faithful and conservative algebraic functor.

11.37 Definition. We denote by

$$Alg^1 \colon (Th^1)^{op} \to ALG^1$$

the 2-functor assigning to every one-sorted theory  $(\mathcal{T}, T)$  the concrete category  $Alg^{1}(\mathcal{T}, T) = (AlgT: AlgT \to Set)$ , to every 1-cell  $M: (\mathcal{T}_{1}, T_{1}) \to (\mathcal{T}_{2}, T_{2})$  the concrete functor  $Alg^{1}M = (-) \cdot M$ , and to every 2-cell  $\alpha: M \to N$  the natural transformation  $Alg^{1}\alpha: Alg^{1}M \to Alg^{1}N$  whose component at a  $\mathcal{T}_{2}$ -algebra A is  $A \cdot \alpha: A \cdot M \to A \cdot N$ .

**11.38 Theorem.** (One-sorted algebraic duality) The 2-category  $ALG^1$  of onesorted algebraic categories is biequivalent to the dual of the 2-category  $Th^1$  of one-sorted algebraic theories. In fact, the 2-functor

$$Alg^1 \colon (Th^1)^{op} \to ALG^1$$

is a biequivalence.

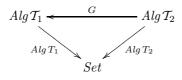

**Proof.** (1)  $Alg^1$  is well-defined and essentially surjective (in the sense of the 2-category  $ALG^1$ , which means surjectivity up to concrete equivalence) by definition of one-sorted algebraic category.

(2) We will prove that for two one-sorted algebraic theories  $(\mathcal{T}_1, \mathcal{T}_1)$  and  $(\mathcal{T}_2, \mathcal{T}_2)$  the functor

$$Th^{1}((\mathcal{T}_{1},T_{1}),(\mathcal{T}_{2},T_{2})) \xrightarrow{Alg^{1}(\mathcal{T}_{1},T_{1}),(\mathcal{T}_{2},T_{2})} ALG^{1}((Alg \mathcal{T}_{2},Alg T_{2}),(Alg \mathcal{T}_{1},Alg T_{1}))$$

1

is an equivalence of categories. The proof that  $Alg^{1}_{(\mathcal{T}_{1},T_{1}),(\mathcal{T}_{2},T_{2})}$  is full and faithful is the same as in Theorem 9.15. It remains to prove that  $Alg^{1}_{(\mathcal{T}_{1},T_{1}),(\mathcal{T}_{2},T_{2})}$  is essentially surjective: consider a concrete functor

It is our task to find a theory morphism  $M: (\mathcal{T}_1, \mathcal{T}_1) \to (\mathcal{T}_2, \mathcal{T}_2)$  with  $G \simeq Alg^1 M$ . We have the left adjoint  $F_T$  of 11.21 and we denote by  $F: Alg \mathcal{T}_1 \to Alg \mathcal{T}_2$  a left adjoint of G. The commutativity of the above triangle yields a natural isomorphism

$$\psi\colon F_{T_2}\to F\cdot F_{T_1}$$

We are going to prove that  $F \cdot Y_{\mathcal{T}_1}$  factorizes (up to natural isomorphism) through  $Y_{\mathcal{T}_2}$ :

$$\begin{array}{cccc} \mathcal{T}_{1}^{op} & \xrightarrow{Y_{\mathcal{T}_{1}}} & Alg \,\mathcal{T}_{1} & [11.1] \\ & & & \downarrow^{P} \\ M^{op} & & & \downarrow^{F} \\ \mathcal{T}_{2}^{op} & \xrightarrow{Y_{\mathcal{T}_{2}}} & Alg \,\mathcal{T}_{2} \end{array}$$

We define  $M: \mathcal{T}_1 \to \mathcal{T}_2$  to be the identity on objects. Consider a morphism  $f: t \to s$  in  $\mathcal{T}_1$ . Since  $Y_{\mathcal{T}_2}$  is full and faithful, there exists a unique morphism  $Mf: Mt \to Ms$  such that the following diagram commutes

$$\begin{array}{c|c} Y_{\mathcal{T}_{2}}M(s) = Y_{\mathcal{T}_{2}}T_{2}(s) = F_{T_{2}}(s) \xrightarrow{\psi_{s}} FF_{T_{1}}(s) = FY_{\mathcal{T}_{1}}T_{1}(s) = FY_{\mathcal{T}_{1}}(s) & [11.2] \\ & & \downarrow \\ & & \downarrow \\ & & \downarrow \\ Y_{\mathcal{T}_{2}}M(f) \downarrow & & \downarrow \\ & & \downarrow$$

The equalities  $F_{T_i} \cdot Y_{\mathcal{N}} = Y_{\mathcal{T}_i} \cdot T_i^{op}$  (i = 1, 2) for the embedding  $Y_{\mathcal{N}} \colon \mathcal{N}^{op} \to Set$  come from 11.21. The functoriality of

$$M: \mathcal{T}_1 \to \mathcal{T}_2$$

follows from the uniqueness of Mf. Moreover, since the isomorphism  $\psi$  is natural, if  $f = T_1g$  for some  $g: t \to s$  in  $\mathcal{N}$  then  $Mf = T_2g$ . Diagram [11.2] gives also the natural isomorphism needed in [11.1]. This finishes the proof:  $F \simeq M^*$  by 9.3, and then  $G \simeq Alg M$ .

11.39 Remark. One can modify this duality by restricting to uniquely transportable algebraic categories (13.16). One gets a dual equivalence (rather then a biequivalence). This new duality exclude the categories AlgT as such, but replaces them by equivalent categories consisting of algebras for equational theories. This result, established in Appendix C, gives an alternative approach to the classical duality between finitary monads and finitary monadic categories over *Set* presented in Appendix A.

#### Historical Remarks for Chapter 11

In his dissertation [60] F. W. Lawvere presents the name algebraic category for one equivalent to the category  $Alg \mathcal{T}$  of algebras of a one-sorted algebraic theory. Our decision to use *concrete* equivalence is motivated by the precise analogy one gets to finitary monadic categories over *Set* (see Appendix A).

108

## CHAPTER 11. ONE-SORTED ALGEBRAIC CATEGORIES

Another variant, based on pseudo-concrete functors in place of the concrete ones, is to take all categories pseudo-concretely equivalent to the categories Alg T above. This is shortly mentioned in Appendix C.

## CHAPTER 11. ONE-SORTED ALGEBRAIC CATEGORIES

## Chapter 12

## Algebras for an endofunctor

The aim of this chapter is to show how limits and colimits are constructed in categories of algebras for a finitary endofunctor of *Set* and, in particular, in the category of  $\Sigma$ -algebras. These results are actually true for finitary endofunctors of all locally finitely presentable categories, the proofs are the same. In the special case of *Set* we also characterize the finitary endofunctors as precisely the quotients of the polynomial endofunctors  $H_{\Sigma}$ . We will prove in 13.23 that the category of algebras for a finitary endofunctor of *Set* is a one-sorted algebraic category.

## 12.1 Remark.

1. The concept of *H*-algebra in 2.25 can be formulated for the endofunctor *H* of an arbitrary category  $\mathcal{K}$ : it is a pair (A, a) consisting of an object *A* and a morphism  $a: HA \to A$ . The category

H-Alg

has as objects *H*-algebras and as morphisms from (A, a) to (B, b) those morphisms  $f: A \to B$  for which  $f \cdot a = b \cdot Hf$ .

2. We denote by

 $U_H \colon H\text{-}Alg \to \mathcal{K}$ 

the canonical forgetful functor  $(A, a) \mapsto A$ .

3. In the present chapter we restrict ourselves to finitary endofunctors H of *Set.* See also 12.17.

**12.2 Remark.** We want to show how colimits of *H*-algebras are obtained. We begin with the simplest case: the initial *H*-algebra. We will prove that it can be obtained by iterating the unique morphism  $u: \emptyset \to H\emptyset$ . More precisely, let us form the  $\omega$ -chain

$$\emptyset \xrightarrow{u} H \emptyset \xrightarrow{Hu} H^2 \emptyset \xrightarrow{H^2 u} H^3 \emptyset \longrightarrow \cdots$$

We call it the *initial chain* of H. Its colimit

$$I = colim_{n \in \mathbb{N}} H^n \emptyset$$

carries the structure of an  $H\mbox{-}algebra.$  Indeed, since H preserve colimits of  $\omega\mbox{-}chains,$ 

$$HI \simeq colim_{n \in \mathbb{N}} H(H^n \emptyset) \simeq colim_{n \in \mathbb{N}} H^n \emptyset = I.$$

We denote by  $i: HI \to I$  the canonical isomorphism. More detailed, denote by

$$v_n \colon H^n \emptyset \to I \quad (n \in \mathbb{N})$$

a colimit cocone for I. Then  $i: HI \to I$  is defined by

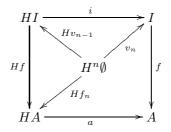

$$i \cdot Hv_{n-1} = v_n$$
 for all  $n \ge 1$ .

**12.3 Lemma.** The H-algebra  $i: HI \rightarrow I$  is initial.

**Proof.** For every algebra  $a: HA \to A$  define a cocone  $f_n: H^n \emptyset \to A$  of the initial chain as follows:  $f_0: \emptyset \to A$  is unique and

$$f_{n+1} = a \cdot H f_n \colon H H^n \emptyset \to A$$
.

The unique morphism  $f: I \to A$  with  $f \cdot v_n = f_n$   $(n \in \mathbb{N})$  is a homomorphism: since the cocone  $(Hv_n)$  is a colimit cocone, thus collectively epimorphic, this follows from the commutative diagram

Conversely, if  $f: I \to A$  is a homomorphism, the above diagram proves that for every  $n \ge 1$  the above morphism  $f_n$  is equal to  $f \cdot v_n$ . This shows the uniqueness.

12.4 Example. We describe the initial  $H_{\Sigma}$ -algebra for the polynomial functor

$$H_{\Sigma}X = \coprod_{k \in \mathbb{N}} \Sigma_k \times X^k$$

by applying labelled trees.

Recall that a *tree* is a directed graph with a distinguished node (root) such that for every node there exists a unique path from the root into it. We work with *ordered trees*, that is, for every node the set of children nodes is linearly

February 1, 2010

112

ordered ("from left to right"). Trees which are isomorphic for an isomorphism respecting the ordering and the labels are identified.

For every signature  $\Sigma$ , by a  $\Sigma$ -tree is meant a tree labelled in  $\Sigma$  so that every node has the number of children equal to the arity of its label. More generally, given a set X of variables, by a  $\Sigma$ -tree on X is meant a tree labelled in  $\Sigma + X$ in such a way that every node with n > 0 children has a label in  $\Sigma_n$  and every leaf has a label in  $\Sigma_0 + X$ .

Initial  $H_{\Sigma}$ -algebra: We can represent  $H_{\Sigma} \emptyset = \Sigma_0$  by the set of all singleton trees labelled by elements of  $\Sigma_0$ . Given a tree representation of  $H_{\Sigma}^k \emptyset$ , we represent

$$H_{\Sigma}^{k+1} \emptyset = \prod_{n \in \mathbb{N}} \Sigma_n \times (H_{\Sigma}^k \emptyset)^n$$

by the set of all trees

$$[12.1]$$

with  $\sigma \in \Sigma_n$  and  $p_1, \ldots, p_n \in H^k_{\Sigma} \emptyset$ . In this way we see that for every  $k \in \mathbb{N}$ 

 $H_{\Sigma}^k \emptyset = \text{ all } \Sigma \text{-trees of depths less than } k.$ 

The above  $\omega$ -chain is the chain of inclusion maps  $\emptyset \subseteq H_{\Sigma} \emptyset \subseteq H_{\Sigma}^2 \emptyset \subseteq \ldots$  and its colimit

$$I = \bigcup_{k \in \mathbb{N}} H^k_{\Sigma}(\emptyset)$$

is the set of all finite  $\Sigma$ -trees. The algebraic structure  $i: H_{\Sigma}I \to I$  is given by tree-tupling: to every *n*-tuple of trees corresponding to the summand of  $\sigma \in \Sigma_n$  it assigns the tree [12.1] above.

**12.5 Remark.** Free *H*-algebras. Let *H* be a finitary endofunctor of *Set*. We now describe free *H*-algebras, that is, a left adjoint of the forgetful functor  $U_H$ . For every set *X*, the endofunctor

$$H(-) + X$$

is also finitary. Therefore, following 12.3, it has an initial algebra.

**12.6 Proposition.** The free H-algebra on X is the initial algebra for the endofunctor H(-) + X.

Explicitly, if  $H^*X$  is the initial algebra for H(-) + X with structure

$$i_X \colon HH^*X + X \to H^*X,$$

then the components

$$\varphi_X \colon HH^*X \to H^*X \text{ and } \eta_X \colon X \to H^*X$$

of  $i_X$  form the algebra structure and the universal morphism, respectively. **Proof.** This follows easily from the observation that to specify an algebra for H(-) + X on an set A means to specify an algebra  $HA \to A$  for H and a function  $X \to A$ .

**12.7 Corollary.** The free H-algebra on X is the colimit of the  $\omega$ -chain

 $\emptyset \to H\emptyset + X \to H(H\emptyset + X) + X \to \dots$ 

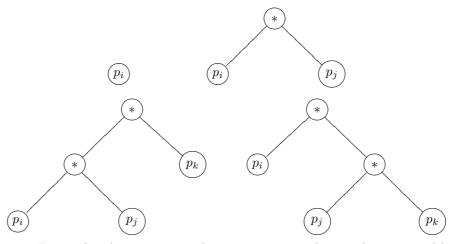

**12.8 Notation.**  $F_H: Set \to H-Alg$  denotes the left adjoint of  $U_H$ . In case  $H = H_{\Sigma}$  we use  $F_{\Sigma}$  instead of  $F_{H_{\Sigma}}$ .

**12.9 Example.** We describe the free  $H_{\Sigma}$ -algebra on an set X. Observe that

$$H_{\Sigma}(-) + X = H_{\overline{\Sigma}}$$

for the signature  $\overline{\Sigma}$  obtained from  $\Sigma$  by adding nullary operation symbols from X. Thus, the description of initial algebra in 12.4 immediately yields a description of the free  $H_{\Sigma}$ -algebra  $F_{\Sigma}X$  on X as the algebra of all finite  $\Sigma$ -trees on X. That is, finite labelled trees with leaves labelled in  $X + \Sigma_0$ , and nodes with n > 0 children labelled in  $\Sigma_n$ . The operations of  $F_{\Sigma}X$  are given by tree-tupling. The universal morphism assigns to a variable  $x \in X$  the singleton tree labelled x.

**12.10 Example.** For the signature  $\Sigma$  of a single binary operation \*, we have a description of  $F_{\Sigma}X$  for  $X = \{p_1, p_2, p_3\}$  as all binary trees with leaves labelled by  $p_1, p_2, p_3$ . Examples:

**12.11 Example.** A commutative binary operation: this can be expressed by the functor H assigning to every set X the set HX of all unordered pairs in X, and to every function f the function Hf acting as f componentwise.

An H-algebra is a set with a commutative binary operation. The free algebra on X is the colimit of the chain

$$\emptyset \to H\emptyset + X = X \to HX + X \to H(HX + X) + X \to \dots$$

We can represent the elements of HZ as binary non-ordered trees with both subtrees elements of Z, then we see that the *n*-th set in the above chain consists of precisely all binary non-ordered trees of depth less than n with leaves labelled in X. Consequently the initial algebra is

IX = all unordered binary trees over X.

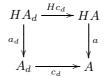

**12.12 Proposition.** For every finitary endofunctor H on Set the category H-Alg has

- (a) limits and
- (b) sifted colimits

preserved by the forgetful functor.

We know from 6.30 that H preserves sifted colimits. We can generalize (b) to say: for every type of colimits preserved by H the category H-Alg has colimits of that type preserved by  $U_H$ .

**Proof.** We prove the more general formulation of (b), the proof of (a) is analogous. Let  $D: \mathcal{D} \to H\text{-}Alg$  be a diagram with objects  $Dd = (A_d, a_d)$  and let  $A = colim A_d$  be the colimit of  $U_H \cdot D$  in Set with the colimit cocone  $c_d: A_d \to A$ . If H preserves this colimit, there exists a unique H-algebra structure  $a: HA \to A$  turning each  $c_d$  into a homomorphism. In fact, the commutative squares

define a unique a since (i)  $c_d \cdot a_d$  is a cocone of  $U_H \cdot D$  and (ii)  $Hc_d$  is the colimit cocone of  $H \cdot U_H \cdot D$ . It is easy to see that the algebra (A, a) is a colimit of D in H-Alg with the cocone  $c_d$ .

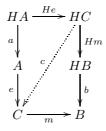

**12.13 Theorem.** For every finitary endofunctor H on Set the category H-Alg is cocomplete. It also has regular factorizations of morphisms preserved by the forgetful functor.

**Proof.** (1) We start with the latter statement. Observe that regular epimorphisms split in *Set* and therefore *H* preserves them. Given a homomorphism  $h: (A, a) \to (B, b)$  in *H*-Alg and a factorization  $h = m \cdot e$  with

 $e\colon A\to C\;$  a regular epimorphism ,  $\;m\colon C\to B\;$  a monomorphism

in Set, use the diagonal fill-in to obtain an H-algebra structure  $c: HC \to C$ 

turning e and m into homomorphisms:

Since  $U_H$  is faithful, m in a monomorphism in H-Alg. And e is a regular epimorphism in H-Alg because given a pair  $u, v \colon X \rightrightarrows A$  with coequalizer e in Set, the corresponding homomorphisms  $\overline{u}, \overline{v} \colon F_H X \to A$  from the free H-algebra have the coequalizer e in H-Alg.

(2) Arguing as in 4.1, to prove that H-Alg is cocomplete it is sufficient to prove that it has finite coproducts. Since by 12.3 H-Alg has initial object, it remains to consider binary coproducts. Thus, we are to prove that the diagonal functor  $\Delta: H$ - $Alg \rightarrow H$ - $Alg \times H$ -Alg has a left adjoint, see 0.11. Since by 12.12 the category H-Alg is complete, it is sufficient (using the Adjoint Functor Theorem 0.8) to find a solution set for every pair  $(A_1, a_1), (A_2, a_2)$  of H-algebras. That is, we need a set of cospans

$$(A_1, a_1) \xrightarrow{f_1} (C, c) \xleftarrow{f_2} (A_2, a_2)$$

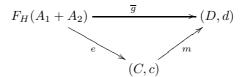

in H-Alg through which all cospans factorize. Consider the coproduct

$$A_1 \xrightarrow{c_1} A_1 + A_2 \xleftarrow{c_2} A_2$$

in Set, denote by  $f: A_1 + A_2 \to C$  the morphism induced by the cospan  $(f_1, f_2)$ , and let  $\overline{f}: F_H(A_1 + A_2) \to (C, c)$  be the homomorphism corresponding to f by adjunction. We claim that a solution set is provided by those cospans  $(f_1, f_2)$ such that  $\overline{f}$  is a regular quotient of  $F_H(A_1 + A_2)$ . This is indeed a set because  $\overline{f}$  is a regular epimorphism also in Set. For any cospan

$$(A_1, a_1) \xrightarrow{g_1} (D, d) \xleftarrow{g_2} (A_2, a_2)$$

consider the regular factorization in H-Alg

We get a new cospan in Set by defining

$$f_i: A_i \xrightarrow{c_i} A_1 + A_2 \xrightarrow{\eta_{A_1+A_2}} F_H(A_1 + A_2) \xrightarrow{e} C \quad (i = 1, 2)$$

(where  $\eta$  is the unit of the adjunction  $F_H \dashv U_H$ ). The cospan  $(g_1, g_2)$  factorizes through  $(f_1, f_2)$  because  $g_i = m \cdot f_i$ . Moreover,  $(f_1, f_2)$  is a cospan in H-Alg: this follows easily from the fact that  $g_i$  and m are homomorphisms of H-algebras and m is a monomorphism in Set. Finally,  $(f_1, f_2)$  has the desired property because  $\overline{f} = e$ .

12.14 Remark. So far we have mentioned, besides the polynomial functors  $H_{\Sigma}$ , only one finitary functor that is not polynomial, see 12.11. And that functor is an obvious quotient of the polynomial functor  $H_{\Sigma}X = X \times X$ .

In general a *quotient* of a functor H is represented by a natural transformation  $\alpha: H \to \overline{H}$  with epimorphic components. We now prove that finitary endofunctors of *Set* are indeed precisely the quotients of the polynomial ones:

**12.15 Theorem.** For an endofunctor H on Set the following conditions are equivalent:

- 1. H is finitary,
- 2. H is a quotient of a polynomial functor

and

3. every element of HX lies in the image of Hi for the inclusion  $i: Y \to X$  of a finite subset Y.

**Proof.**  $3 \Rightarrow 1$ : Let

$$D: \mathcal{D} \to Set$$

be a filtered diagram with a colimit cocone

 $c_d \colon Dd \to C \quad (d \in \operatorname{obj} \mathcal{D}).$ 

We prove that the diagram  $D \cdot H$  has the colimit

$$Hc_d: HDd \to HC$$

in Set. For that it is by 0.6 sufficient to verify that

(a) every element x of HC lies in the image of  $Hc_d$  for some d

and

(b) given elements  $y_1, y_2 \in HDd$  merged by  $Hc_d$ , there exists a connecting morphism  $f: d \to d'$  of  $\mathcal{D}$  with Hf also merging  $y_1$  and  $y_2$ .

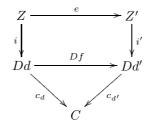

For (a) choose a finite subset  $i: Y \to X$  with x lying in the image of Hi. Since C = colim Dd is a filtered colimit in Set, there exists a factorization

 $i = c_d \cdot j$  for some  $d \in \operatorname{obj} \mathcal{D}$  and  $j: Y \to Dd$ .

117

Thus x lies in the image of  $Hc_d$ .

For (b) choose a finite subset  $i: \mathbb{Z} \to Dd$  such that  $y_1, y_2$  lie in the image of Hi. Since C = colim Dd is a filtered colimit, there exists a connecting morphism  $f: d \to d'$  such that the domain restriction of  $c_{d'}$  to the image  $i': \mathbb{Z}' \to Dd'$  of  $f \cdot i$  is a monomorphism. We obtain a commutative diagram

for some morphism e such that  $c_{d'} \cdot i'$  is a monomorphism. Without loss of generality  $Z' \neq \emptyset$  provided  $C \neq \emptyset$ . Then  $c_{d'} \cdot i'$  is a split monomorphism. Then  $H(c_{d'} \cdot i')$  also is a split monomorphism, and we conclude that HDf merges  $y_1, y_2$ .

 $1 \Rightarrow 3$ : Obvious from the description of fittered colimits in *Set* (see 0.6).

 $1 \Rightarrow 2$ : This follows from Yoneda Lemma. Define the signature  $\Sigma$  by using, for every  $n \in \mathbb{N}$ , the elements of Hn as the operation symbols  $\sigma$  of arity  $n \in \mathbb{N}$ . Shortly:  $Hn = \Sigma_n$ . Then we have a natural transformation  $\alpha: H_{\Sigma} \to H$ which, given an operation symbol  $\sigma \in \Sigma_n$  (that is,  $\sigma \in Hn$ ), assigns to the corresponding *n*-tuple  $f: n \to Z$  the value

$$\alpha_Z(\sigma(f)) = Hf(\sigma) \,.$$

In other words, the component of  $\alpha_Z$  at the functor Set(n, -) corresponding to  $\sigma \in \Sigma_n$  is the Yoneda transformation of  $\sigma$ . Condition 3. tells us precisely that  $\alpha_Z$  is a surjective map for every set Z.

 $2 \Rightarrow 3$ : Every polynomial functor satisfies condition 3. Indeed, to choose an element  $x \in H_{\Sigma}X$  means to fix a symbol  $\sigma \in \Sigma_n$ , so that  $x = (x_1, \ldots, x_n) \in X \times \ldots \times X$ . Therefore, as Y we can take  $\{x_1, \ldots, x_n\}$ .

Let now  $\alpha: H_{\Sigma} \to H$  be a quotient, and fix an element  $x \in HX$ . Since  $\alpha_X: H_{\Sigma}X \to HX$  is surjective, there exists  $y \in H_{\Sigma}$  such that  $\alpha_X(y) = x$ . Find a finite subset  $i: Y \to X$  such that  $y = (H_{\Sigma}i)(\overline{y})$  for some  $\overline{y} \in H_{\Sigma}$ . By naturality of  $\alpha$  we have

$$x = \alpha_X(H_{\Sigma}i)(\overline{y}) = (Hi)\alpha_Y(\overline{y}).$$

12.16 Remark. In 13.23 we will see that for every presentation of a functor H as a quotient functor of  $H_{\Sigma}$ , the category of H-algebras can be viewed as an equational category of  $\Sigma$ -algebras.

12.17 Remark. Most of the result in this chapter has an obvious generalization to endofunctors H of cocomplete categories  $\mathcal{K}$  which preserve sifted colimits.

## CHAPTER 12. ALGEBRAS FOR AN ENDOFUNCTOR

- 1. The initial chain of 12.2 is defined by denoting by  $\emptyset$  an initial object of  $\mathcal{K}$  and using the unique morphism  $u \colon \emptyset \to H\emptyset$ . The corresponding *H*-algebra is initial.
- 2. The free *H*-algebra on an object *X* of *K* is the initial algebra for the endofunctor H(-) + X.
- 3. The category H-Alg is complete and cocomplete, and the forgetful functor into  $\mathcal{K}$  preserves limits and sifted colimits.

## Historical Remarks for Chapter 12

Algebras for an endofunctor were introduced by J. Lambek in [59]. The initial algebra construction 12.2 and its free-algebra variation 12.7 stem from [1]. Factorizations and colimits in categories H-Alg were studied in [2].

The fact that finitary endofunctors on Set yield one-sorted algebraic categories follows from the work of M. Barr [17] on free monads, see Appendix A.

## CHAPTER 12. ALGEBRAS FOR AN ENDOFUNCTOR

## Chapter 13

## Equational categories of $\Sigma$ -algebras

This chapter shows the precise relationship of the classical one-sorted general algebra and algebraic theories: we prove that every equational category of  $\Sigma$ -algebras is a one-sorted algebraic category (in the sense of Definition 11.13), and conversely, every one-sorted algebraic category can be presented by equations of  $\Sigma$ -algebras for some (one-sorted) signature. (The case of S-sorted signatures is treated in Chapter 14.)

We have introduced varieties in algebraic categories in Chapter 10. The classical equational categories, i.e., full subcategories of  $\Sigma$ -algebras presented by equations, are a special case. In fact, we demonstrate that equations in the sense of pairs of terms over  $\Sigma$  canonically correspond to equations in the sense of Definition 10.1.

We also prove that the categorical concepts of finitely presentable or finitely generated object have in categories of  $\Sigma$ -algebras their classical meaning.

13.1 Remark. We described a left adjoint

$$F_{\Sigma} \colon Set \to \Sigma\text{-}Alg$$

of the forgetful functor  $U_{\Sigma}: \Sigma - Alg \to Set$  in 12.9 (recall from 2.25 that  $H_{\Sigma}$ - $Alg = \Sigma - Alg$ ). The more standard description is that  $F_{\Sigma}X$  is the following  $\Sigma$ -term-algebra: the underlying set is the smallest set such that

- every element  $x \in X$  is a  $\Sigma$ -term

and

- for every  $\sigma \in \Sigma$  of arity n and for every n-tuple of  $\Sigma$ -terms  $p_1, \ldots, p_n$  we have a  $\Sigma$ -term  $\sigma(p_1, \ldots, p_n)$ .

The  $\Sigma$ -algebra structure on  $F_{\Sigma}X$  is given by the formation of terms  $\sigma(p_1, \ldots, p_n)$ . This defines a functor  $F_{\Sigma}: Set \to \Sigma$ -Alg on objects. To define it on morphisms  $f: X \to Z$ , let  $F_{\Sigma}f$  be the function which in every term p of  $F_{\Sigma}X$  substitutes for every variable  $x \in X$  the variable f(x). More explicitly:

- if 
$$x \in X$$
, then  $F_{\Sigma}f(x) = f(x)$ ,

- if  $p_1, \ldots, p_n \in F_{\Sigma}X$  and  $\sigma \in \Sigma_n$ , then

$$F_{\Sigma}f(\sigma(p_1,\ldots,p_n)) = \sigma(F_{\Sigma}f(p_1),\ldots,F_{\Sigma}f(p_n)).$$

It is easy to verify that  $F_{\Sigma}$  is a well-defined functor which is naturally isomorphic to the  $\Sigma$ -tree functor of 12.9. Thus, we have  $F_{\Sigma} \dashv U_{\Sigma}$ . The unit of the adjunction is the inclusion of variables into the set of  $\Sigma$ -terms:  $\eta_X : X \to F_{\Sigma}X$ .

**13.2 Notation.** Suppose that a set of "standard variables"  $x_0, x_1, x_2, \ldots$  is given. Then the free  $\Sigma$ -algebras

$$F_{\Sigma}\{x_0,\ldots,x_{n-1}\}$$

yield, by 11.24, a one-sorted theory for  $\Sigma$ -Alg. We denote this theory by

 $(\mathcal{T}_{\Sigma}, \mathcal{T}_{\Sigma})$ .

Thus, morphisms from n to 1 in  $\mathcal{T}_{\Sigma}$  are the  $\Sigma$ -terms in variables  $x_0, \ldots, x_{n-1}$ . General hom-sets are given by k-tuples of these terms:

$$\mathcal{T}_{\Sigma}(n,k) = (F_{\Sigma}n)^k \,.$$

And  $T_{\Sigma} \colon \mathcal{N} \to \mathcal{T}_{\Sigma}$  assigns to every function  $g \colon k \to n$ , that is,  $g \in \mathcal{N}(n, k)$ , the *k*-tuple of terms

$$x_{g(0)}, \ldots, x_{g(k-1)}$$
.

**13.3 Lemma.** The category  $\Sigma$ -Alg is concretely equivalent to the category of algebras of  $(\mathcal{T}_{\Sigma}, \mathcal{T}_{\Sigma})$ .

**Proof.** Define  $E: \Sigma - Alg \to Alg \mathcal{T}_{\Sigma}$  on objects as follows. For a  $\Sigma$ -algebra (A, a), the corresponding functor from  $\mathcal{T}_{\Sigma}$  to *Set* is given on objects by  $n \mapsto A^n$  and on morphisms  $t: n \to 1$  by the function  $A^n \to A$  of evaluation of the term t in the given algebra. This function takes a map  $f: n \to A$  to  $\overline{f}(t) \in A$ , where  $\overline{f}: F_{\Sigma}\{x_0, \ldots, x_{n-1}\} \to (A, a)$  is the unique homomorphism extending f.

Conversely, if B is a  $\mathcal{T}_{\Sigma}$ -algebra we get a  $\Sigma$ -algebra structure on the set B1 as follows: if  $\sigma \in \Sigma_n$ , then  $\sigma(x_0, \ldots, x_{n-1}) \in F_{\Sigma}n = \mathcal{T}_{\Sigma}(n, 1)$  and this yields an *n*-ary operation on B1 by applying B to that morphism (recall that Bn is isomorphic to the *n*-th power of B1).

This gives a concrete equivalence 
$$E: \Sigma - Alg \to Alg \mathcal{T}_{\Sigma}$$
.

**13.4 Definition.** Given signatures  $\Sigma$  and  $\Sigma'$ , a morphism of signatures is a function  $f: \Sigma \to \Sigma'$  preserving the arities. This leads to the category of signatures Sign – this is just the slice category  $Set \downarrow \mathbb{N}$ .

February 1, 2010 122

**13.5 Definition.** For every one-sorted algebraic theory  $(\mathcal{T}, T)$  we define the signature

 $\mathcal{C}(\mathcal{T}, T)$ 

as the signature whose  $n\text{-}\mathrm{ary}$  symbols are precisely the morphisms from n to 1 in  $\mathcal{T}$  :

$$(\mathcal{C}(\mathcal{T},T))_n = \mathcal{T}(n,1)$$
.

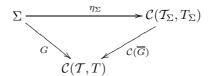

This construction can be easily extended to morphisms of one-sorted theories.

**13.6 Example.** The signature  $C(\mathcal{T}_{\Sigma}, T_{\Sigma})$  has all  $\Sigma$ -terms in variables  $x_0, \ldots, x_{n-1}$  as *n*-ary operation symbols. Therefore, there is a canonical morphism of signatures

$$\eta_{\Sigma} \colon \Sigma \longrightarrow \mathcal{C}(\mathcal{T}_{\Sigma}, T_{\Sigma})$$

given by  $\eta_{\Sigma}(\sigma) = \sigma(x_0, \ldots, x_{n-1}) \in F_{\Sigma}n$  for any  $\sigma$  of arity n.

**13.7 Proposition.** (A free one-sorted theory on a signature) For every signature  $\Sigma$  the theory  $(\mathcal{T}_{\Sigma}, \mathcal{T}_{\Sigma})$  is free on  $\Sigma$ . That is, given a one-sorted theory  $(\mathcal{T}, \mathcal{T})$  for every morphism  $G: \Sigma \to \mathcal{C}(\mathcal{T}, \mathcal{T})$  of signatures there exists a unique morphism  $\overline{G}: (\mathcal{T}_{\Sigma}, \mathcal{T}_{\Sigma}) \to (\mathcal{T}, \mathcal{T})$  of one-sorted theories such that  $\mathcal{C}(\overline{G}) \cdot \eta_{\Sigma} = G$ 

**Proof.** (1) We define a functor  $\overline{G}: \mathcal{T}_{\Sigma} \to \mathcal{T}$  on objects by  $n \mapsto n$  and on morphisms  $p \in \mathcal{T}_{\Sigma}(k, 1)$ , that is  $\Sigma$ -terms on  $\{x_0, \ldots, x_{k-1}\}$ , by structural induction:

- (i) For variables  $x_i \in \mathcal{T}_{\Sigma}(k, 1)$  put  $\overline{G}x_i = Tp_i^k$ , the chosen projection in  $\mathcal{T}(k, 1)$ .
- (ii) Given  $p = \sigma(p_1, \ldots, p_n)$  where  $\sigma \in \Sigma_n$ ,  $p_i \in \mathcal{T}(k, 1)$   $(i = 1, \ldots, n)$  and  $\overline{G}p_i$  are defined already, put

$$\overline{G}p: k \xrightarrow{\langle \overline{G}p_1, \dots, \overline{G}p_n \rangle} n \xrightarrow{G\sigma} 1$$

It is clear that  $\overline{G} \cdot T_{\Sigma} = T$  and  $\mathcal{C}(\overline{G}) \cdot \eta_{\Sigma} = G$ .

(2) Uniqueness: Let  $M: (\mathcal{T}_{\Sigma}, \mathcal{T}_{\Sigma}) \to (\mathcal{T}, T)$  be a morphism of one-sorted theories with  $\mathcal{C}(M) \cdot \eta_{\Sigma} = G$ . Since M preserves finite products, all we have to prove is that it is determined when precomposed by  $\eta_{\Sigma}$ . This is the case, indeed:

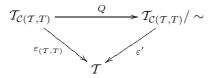

(i) For variables  $x_i \in \mathcal{T}_{\Sigma}(k, 1)$  use  $M \cdot T_{\Sigma} = T$ , so that  $M(\eta_{\Sigma}(x_i))$  is the *i*-th projection  $p_i^k$ .

(ii) Consider  $p = \sigma(p_1, \ldots, p_n)$  with  $\sigma \in \Sigma_n$  and  $p_i \in \mathcal{T}(k, 1)$   $(i = 1, \ldots, n)$ . Since  $\sigma(p_1, \ldots, p_n) = \sigma(x_1, \ldots, x_n) \cdot \langle p_1, \ldots, p_n \rangle$  in  $\mathcal{T}_{\Sigma}$ , we have that  $Mp = M(\eta_{\Sigma}(\sigma)) \cdot \langle Mp_1, \ldots, Mp_m \rangle$ .

**13.8 Remark.** Let  $(\mathcal{T}, T)$  be a one-sorted theory. If we apply the construction described in the first part of the proof of 13.7 to the identity morphism on  $\mathcal{C}(\mathcal{T}, T)$ , we get a morphism

$$\varepsilon_{(\mathcal{T},T)} \colon \mathcal{T}_{\mathcal{C}(\mathcal{T},T)} \longrightarrow (\mathcal{T},T)$$

of one-sorted theories. It is clearly full and then, by 10.13, the unique functor  $\varepsilon'$  making commutative the following diagram of morphisms of one-sorted theories is an isomorphism

Therefore:

1.  $(\mathcal{T}, T)$  is a quotient of the free one-sorted theory  $\mathcal{T}_{\mathcal{C}(\mathcal{T},T)}$ .

2. Alg  $\mathcal{T}$  is a variety of  $\mathcal{C}(\mathcal{T}, T)$ -algebras.

In order to improve the previous result we need the notion of equational category of  $\Sigma$ -algebras. We start comparing the classical notion of equation with the one introduced in Chapter 10.

## 13.9 Remark.

1. Classically equations are expressions

t = t'

where t and t' are terms in variables  $x_0, \ldots, x_{n-1}$  for some n. This is a special case of 10.1: here we have a parallel pair  $t, t': n \Rightarrow 1$  in the theory  $\mathcal{T}_{\Sigma}$ . Also, a  $\Sigma$ -algebra (A, a) satisfies this equation in the classical sense (that is, for every interpretation  $f: \{x_0, \ldots, x_{n-1}\} \to A$  we have  $\overline{f}(t) = \overline{f}(t')$ ) iff the corresponding  $\mathcal{T}_{\Sigma}$ -algebra satisfies this equation in the sense of 10.1.

2. In fact, for the theory  $\mathcal{T}_{\Sigma}$  equations in the sense of 10.1 are equivalent to the classical equations: given a parallel pair

$$t, t' \colon n \rightrightarrows k$$
 in  $\mathcal{T}_{\Sigma}$ 

and given the k projections  $p_i^k : k \to 1$  (i = 0, ..., k - 1) specified by the functor  $T_{\Sigma} : \mathcal{N} \to \mathcal{T}_{\Sigma}$ , we get a k-tuple of equations

$$p_i^k \cdot t = p_i^k \cdot t'$$

in the classical sense. It is clear that a  $\Sigma$ -algebra satisfies each of these k equations iff the corresponding  $T_{\Sigma}$ -algebra satisfies t = t' in the sense of 10.1.

124

## 13.10 Definition.

1. By an equational category of  $\Sigma$ -algebras is meant a full subcategory of  $\Sigma$ -Alg formed by all algebras satisfying a set E of equations. We denote such a category by

$$(\Sigma, E)$$
-Alg.

The pair  $(\Sigma, E)$  is called an *equational theory*.

2. Equational categories are concrete categories over Set which are, for some signature Σ, equational categories of Σ-algebras.

**13.11 Theorem.** One-sorted algebraic categories are precisely the equational categories.

More detailed: a concrete category over *Set* is one-sorted algebraic iff it is concretely equivalent to an equational category of  $\Sigma$ -algebras for some signature  $\Sigma$ .

**Proof.** (1) Every equational category of  $\Sigma$ -algebras is a one-sorted algebraic category. In fact, following 13.9, the concrete equivalence  $\Sigma$ -Alg  $\simeq$  Alg $\mathcal{T}_{\Sigma}$  of 13.3 restricts to a concrete equivalence between  $(\Sigma, E)$ -Alg and Alg $(\mathcal{T}_{\Sigma}/\sim_E)$ , where  $\sim_E$  is the congruence on  $\mathcal{T}_{\Sigma}$  generated by E (see 10.7).

(2) Conversely, every one-sorted algebraic category is concretely equivalent to an equational category of  $\Sigma$ -algebras. In fact,  $Alg \mathcal{T}$  is equivalent to  $Alg(\mathcal{T}_{\Sigma}/\sim)$  for some congruence  $\sim$  on  $\mathcal{T}_{\Sigma}$  (13.8) and, therefore, to  $(\Sigma, E)$ -Alg where E is the set of all equations u = v where u and v are congruent terms.

**13.12 Example.** Recall that a *semigroup* is an algebra on one associative binary operation. This means that we consider the  $\Sigma$ -algebras with  $\Sigma = \{*\}$  which satisfy the equation

$$(x*y)*z = x*(y*z) .$$

Thus, the theory of semigroups is the quotient theory  $\mathcal{T}_{\Sigma}/\sim$  where  $\sim$  is the congruence generated by the equation above.

**13.13 Example.** Beside the algebraic theory  $\mathcal{T}_{ab}$  of abelian groups of 1.6 we now have a different one, based on the usual equational presentation: let  $\Sigma = \{+, -, 0\}$  with + binary, - unary and 0 nullary. Then a theory of abelian groups is the quotient  $\mathcal{T}_{\Sigma}/\sim$  modulo the congruence on  $\mathcal{T}_{\Sigma}$  generated by the four equations

$$\begin{array}{rcrcrcrc} (x+y)+z & = & x+(y+z) \\ & x+y & = & y+x \\ & x+0 & = & 0 \\ & x+(-x) & = & 0 \end{array}$$

**13.14 Example.** Recall that a *monoid* is a semigroup (M, \*) with a unit. We can consider the category of all monoids as the category  $(\Sigma, E)$ -Alg where  $\Sigma$ 

has a binary symbol \* and a nullary symbol e, and E contains the associativity of \* and the equations

 $\begin{array}{rcl} x & = & x * e \\ x & = & e * x \end{array}$ 

(equivalently, as the category  $Alg(T_{\Sigma}/\sim)$  where  $\sim$  is the congruence generated by the associativity of \* and the equations above).

**13.15 Example.** For every monoid M, an M-set is a pair  $(X, \alpha)$  consisting of a set X and a monoid action  $\alpha \colon M \times X \to X$  (the usual notation is mx in place of  $\alpha(m, x)$ ) such that every element  $x \in X$  satisfies m(m'x) = (m \* m')x for all  $m, m' \in M$ , and ex = x. The homomorphisms  $f \colon (X, \alpha) \to (Z, \beta)$  of M-sets are the functions  $f \colon X \to Z$  with f(mx) = mf(x) for all  $m \in M$  and  $x \in X$ . We can describe this category as  $(\Sigma, E)$ -Alg where  $\Sigma = M$  with all arities equal to 1, and E consists of the equations

$$\begin{array}{rcl} x & = & e \, x \\ (m \ast m') \, x & = & m \, (m' \, x) \end{array}$$

for all  $m, m' \in M$ .

**13.16 Definition.** A concrete category  $U: \mathcal{A} \to \mathcal{K}$  is called:

- 1. Amnestic provided that given an isomorphism  $i: A \to A'$  in  $\mathcal{A}$  with  $Ui = id_{UA}$ , then A = A'. (This implies  $i = id_A$  because U is faithful.)
- 2. Transportable provided that for every object A in  $\mathcal{A}$  and every isomorphism  $i: UA \to X$  in  $\mathcal{K}$  there exists an isomorphism  $j: A \to B$  in  $\mathcal{A}$  with UB = X and Uj = i.
- 3. Uniquely transportable if in 2. the isomorphism j is unique.

### 13.17 Example.

1. For every one-sorted algebraic theory  $(\mathcal{T}, T)$  the concrete category

$$AlgT: AlgT \to Set$$

is transportable – but almost never uniquely transportable (see 11.7). In fact, given a  $\mathcal{T}$ -algebra A and a bijection  $i: A1 \to X$ , let  $B: \mathcal{T} \to Set$  be defined on objects by  $Bn = X^n$  and on morphisms  $f: n \to k$  in the unique way making the powers of i natural:

$$(A1)^{n} \simeq An \xrightarrow{Af} Ak = (A1)^{k}$$

$$\downarrow^{i^{n}} \downarrow \qquad \qquad \downarrow^{i^{k}} \downarrow^{i^{k}}$$

$$X^{n} = Bn \xrightarrow{Bf} Bk = X^{k}$$

Then these powers form a natural isomorphism  $j: A \to B$  with  $j_1 = i$ .

2. For every signature  $\Sigma$  the concrete category

$$U_{\Sigma} \colon \Sigma \text{-} Alg \to Set , \ U_{\Sigma}(A, \sigma^A) = A$$

is uniquely transportable. In fact, given a bijection  $i: A \to X$  there is a unique way of defining, for an *n*-ary symbol  $\sigma \in \Sigma$ , the operation  $\sigma^X$  so that the square

commutes. The same is true for the equational categories of  $\Sigma$ -algebras. For example, the category of abelian groups is uniquely transportable.

3. For every endofunctor H of a category  $\mathcal{K}$  the concrete category

$$U_H \colon H\text{-}Alg \to \mathcal{K} \ , \ \ (A,a) \mapsto A$$

is uniquely transportable. In fact, given an algebra  $a: HA \to A$  and an isomorphism  $i: A \to X$  in  $\mathcal{K}$ , the unique algebra  $x: HX \to X$  for which i becomes a homomorphism is  $x = i \cdot a \cdot Hi^{-1}$ .

## 13.18 Remark.

1. For every concrete category we have

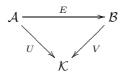

transportable + amnestic  $\Leftrightarrow$  uniquely transportable.

In fact, if  $(\mathcal{A}, U)$  is transportable and amnestic, and if in 13.16.2 we have another isomorphism  $j' \colon A \to B'$  with Uj' = i, use 13.16.1 on the isomorphism  $j' \cdot j^{-1} \colon B \to B'$  to conclude B = B'. Then j = j' since U is faithful.

Conversely, if  $(\mathcal{A}, U)$  is uniquely transportable, then by applying 13.16.3 to  $i = \mathrm{id}_{UA}$  we deduce that it is amnestic.

- 2. Transportability is not invariant under concrete equivalence, thus, not all one-sorted algebraic categories are transportable. For example, let  $E: Set' \rightarrow Set$  be the full subcategory of Set consisting of all cardinal numbers. Then (Set', E) is one-sorted algebraic because it is concretely equivalent to (Set, Id). But it obviously fails to be transportable.
- 3. We will see in 13.21 a converse of 13.17.2: every uniquely transportable one-sorted algebraic category is (up to concrete isomorphism) an equational category.

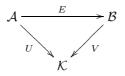

**13.19 Definition.** Given concrete categories  $U: \mathcal{A} \to \mathcal{K}$  and  $V: \mathcal{B} \to \mathcal{K}$  by a *concrete isomorphism* between them we mean a concrete functor

and a functor  $E': \mathcal{B} \to \mathcal{A}$  such that both  $E \cdot E'$  and  $E' \cdot E$  are equal to the identity functors. (Note that such a functor E' is necessarily concrete.) We then say that  $(\mathcal{A}, U)$  and  $(\mathcal{B}, V)$  are *concretely isomorphic*.

**13.20 Lemma.** A concrete equivalence between uniquely transportable concrete categories is a concrete isomorphism.

**Proof.** Given a concrete equivalence

between uniquely transportable categories, we prove that E is bijective on objects – thus it is a (concrete) isomorphism.

(a) If A and A' are objects of  $\mathcal{A}$  with EA = EA', then for the identity morphism of EA there exists, since E is full, a morphism  $f: A \to A'$  with Ef = id. And f is of course an isomorphism in  $\mathcal{A}$ . Since Uf = V(Ef) = id, amnesticity of U implies A = A'.

(b) For every object B of  $\mathcal{B}$  there exists an isomorphism  $i: EA \to B$  in  $\mathcal{B}$  yielding an isomorphism  $Vi: UA \to VB$  in  $\mathcal{K}$ . Let  $j: A \to A'$  be the unique isomorphism in  $\mathcal{A}$  with Uj = Vi. The isomorphism  $Ej \cdot i^{-1}: B \to EA'$  fulfils  $V(Ej \cdot i^{-1}) = Uj \cdot Vi^{-1} = \text{id}$ , thus by amnesticity of V we have B = EA'.  $\Box$ 

**13.21 Corollary.** Uniquely transportable one-sorted algebraic categories are, up to concrete isomorphism, precisely the equational categories.

In fact, this follows from 13.11, 13.17 and 13.20.

Birkhoff's Variety Theorem (10.22) can be restated in the context of  $\Sigma$ -algebras:

**13.22 Theorem.** Let  $\Sigma$  be a signature. A full subcategory  $\mathcal{A}$  of  $\Sigma$ -Alg is equational if and only if it is closed in  $\Sigma$ -Alg under

- (a) products,
- (b) subalgebras,

and

February 1, 2010

128

(c) regular quotients.

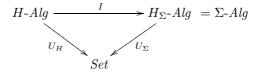

In fact, this follows from 10.22, 11.34 and 13.11.

**13.23 Proposition.** Let  $\Sigma$  be a one-sorted signature and  $H: Set \to Set$  be a quotient of the polynomial functor  $H_{\Sigma}$ . The concrete category H-Alg is concretely isomorphic to an equational category of  $\Sigma$ -algebras.

**Proof.** Let  $\alpha: H_{\Sigma} \to H$  be a natural transformation with epimorphic components. We get a full and faithful functor

$$I: H-Alg \to H_{\Sigma}-Alg \quad I(A, a) = (A, a \cdot \alpha_A).$$

Moreover, I is concrete since the diagram

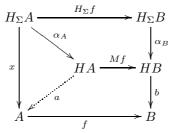

clearly commutes.

Since I is injective on objects, H-Alg is concretely isomorphic to the full subcategory I(H-Alg) of  $\Sigma$ -Alg. We are to prove that I(H-Alg) satisfies the conditions of Proposition 13.22.

(a) Consider the above commutative diagram. Since  $U_H$  preserves and  $U_{\Sigma}$  reflects limits and sifted colimits, I preserves them. In particular, I(H-Alg) is closed in  $\Sigma$ -Alg under products.

(b) Let  $f: (A, x) \to I(B, b)$  be a monomorphism in  $\Sigma$ -Alg (and then in Set). Since  $\alpha_A$  is a strong epimorphism in Set, we get an H-algebra structure on A by diagonal fill-in:

This shows that (A, x) = I(A, a).

(c) First observe that if  $f: I(A, a) \to (B, y)$  is an isomorphism in  $\Sigma$ -Alg, then  $(B, y) \in I(H$ -Alg). Indeed  $f: (A, a) \to (B, b)$  is an isomorphism in H-Alg, where  $b = f \cdot a \cdot Hf^{-1}$ , and I(B, b) = (B, y). (In other words, (H-Alg, I) is transportable, see 13.16.)

Now consider a regular epimorphism  $e: I(A, a) \to (B, y)$  in  $\Sigma$ -Alg. Its kernel pair, being a subobject of  $I(A, a) \times I(A, a)$ , lies in the image of I and we can take its coequalizer (Q, q) in H-Alg. This coequalizer is preserved by I (because it is reflexive, see 3.4). Thus  $I(Q, q) \simeq (B, y)$ .

**13.24 Remark.** In general algebra the concepts of finitely generated and finitely presentable  $\Sigma$ -algebra are defined as follows: a  $\Sigma$ -algebra (A, a) is called

(a) finitely generated if it is generated by a finite set (see 11.10), that is, (A, a) is isomorphic to

$$F_{\Sigma}\{x_1,\ldots,x_n\}/\sim$$

for some congruence  $\sim$  on  $F_{\Sigma}\{x_1, \ldots, x_n\}$ 

and

(b) finitely presentable if it is such a quotient modulo a finitely generated congruence, that is, (A, a) is isomorphic to  $F_{\Sigma}\{x_1, \ldots, x_n\}/\sim$  for some congruence  $\sim$  generated by finitely many equations.

It turns out that these concepts coincide with the categorical concepts of 5.21 and 5.3, respectively. Let us first observe that:

- (1) Every subalgebra generated by a set X (see 11.10) is a regular quotient of the free algebra  $F_{\Sigma}X$ . In fact, let B be the subalgebra of A generated by X and let  $f: F_{\Sigma}X \to A$  be the unique homomorphism extending the inclusion map. Then the image  $f(F_{\Sigma}X)$  is a subalgebra of A because the forgetful functor preserves regular factorizations, see 11.9. This is, obviously, the least subalgebra containing X, and the codomain restriction of f is a regular epimorphism.
- (2) Conversely, every regular quotient  $q: F_{\Sigma}X \to A$  of a free algebra generated by X is "generated by X" – more precisely, the image of the map

$$X \xrightarrow{\eta_{\Sigma}} U_{\Sigma}(F_{\Sigma}X) \xrightarrow{U_{\Sigma}q} U_{\Sigma}A$$

generates A.

**13.25 Proposition.** A  $\Sigma$ -algebra is a finitely generated object of  $\Sigma$ -Alg if and only if it is a regular quotient of a finitely generated free algebra.

**Proof.** (1) Let (A, a) be a finitely generated object of  $\Sigma$ -Alg. Form a diagram in  $\Sigma$ -Alg indexed by the poset of all finite subsets of A by assigning to every such  $X \subseteq A$  the subalgebra  $\overline{X}$  of A generated by X (see 11.10). Given finite subsets X and Z with  $X \subseteq Z \subseteq A$ , the connecting map  $\overline{X} \to \overline{Z}$  is the inclusion map. Then the inclusion homomorphisms  $i_X : \overline{X} \to A$  form a colimit cocone of this directed diagram. Since the functor  $\Sigma$ -Alg(A, -) preserves this colimit, for  $\mathrm{id}_A \in \Sigma$ -Alg(A, A) there exists a finite set X such that  $\mathrm{id}_A$  lies in the image of  $i_X$  – but this proves  $\overline{X} = A$ .

(2) Let us prove that every quotient  $A = F\{x_1, \ldots, x_n\}/\sim$  is finitely generated. Given a directed diagram of subobjects  $B_i$   $(i \in I)$  with a colimit  $B = colim B_i$ , it is our task to prove that  $\Sigma$ -Alg(A, -) preserves this colimit, that is, every homomorphism  $h: A \to B$  factorizes through one of the colimit homomorphisms  $b_i: B_i \to B$ . For the finite set  $\{h(\eta_X(x_k))\}_{k=1}^n$  there exists  $i \in I$  such that this

set lies in the image of  $b_i$ . From that it easily follows that the image of h is contained into the image of  $b_i$ . Since  $b_i$  is a monomorphism, it follows that there exists a homomorphism  $g: A \to B_i$  with  $h = b_i \cdot g$ , as requested.

**13.26 Proposition.** A  $\Sigma$ -algebra is a finitely presentable object of  $\Sigma$ -Alg if and only if it is a regular quotient of a finitely generated free algebra modulo a finitely generated congruence.

**Proof.** (1) Let (A, a) be a finitely presentable object. By 11.28 there exists a coequalizer

$$F_{\Sigma}X \xrightarrow[v]{u} F_{\Sigma}Z \xrightarrow{c} (A, a)$$

with X and Z finite. Let ~ be the congruence generated by the finitely many equations  $u(\eta_{\Sigma}(x)) = v(\eta_{\Sigma}(x))$  where  $x \in X$ , then (A, a) is clearly isomorphic to  $F_{\Sigma}Z/\sim$ : the canonical morphism  $q: F_{\Sigma}Z \to F_{\Sigma}Z/\sim$  is namely also a coequalizer of u and v.

(2) Conversely, let Z be a finite set and ~ a congruence on  $F_{\Sigma}Z$  generated by equations  $t_1 = s_1, \ldots, t_k = s_k$ . For  $X = \{1, \ldots, k\}$  define homomorphisms  $u, v: F_{\Sigma}X \Rightarrow F_{\Sigma}Z$  by

$$u(i) = t_i$$
 and  $v(i) = s_i$  for  $i = 1, ..., k$ .

Then the canonical map  $q: F_{\Sigma}Z \to F_{\Sigma}Z/\sim$  is a coequalizer of u and v. Therefore,  $F_{\Sigma}Z/\sim$  is finitely presentable by 11.28.

#### Historical Remarks for Chapter 13

The material of this chapter is closely related to the classical work of G. Birkhoff [25], for a modern exposition of general algebra see e.g. [37] or [47].

The concepts of (uniquely) transportable and amnestic functor are taken from [4]; some authors use transportability requesting uniqueness as a part of the definition.

### CHAPTER 13. EQUATIONAL CATEGORIES OF $\Sigma$ -ALGEBRAS

## Chapter 14

# S-sorted algebraic categories

In the previous chapters we have considered one-sorted algebraic categories. They are categories equipped with a forgetful functor into Set, like groups, abelian groups, lattices, etc. In computer science one often considers S-sorted algebras, where S is a given nonempty set (of sorts), and algebras are not sets with operations, but rather S-indexed families of sets with operations of given sort. This means that the forgetful functor is into  $Set^S$  rather than into Set. In this chapter we revisit one-sorted algebraic categories generalizing definitions and several results to the S-sorted case, see 14.3.

Analogously to the one-sorted case, where the theory has objects  $X^n$  (which we represented by n alone) and projections  $\pi_i^n \colon X^n \to X$  are specified, in case of S-sorted theories we have objects  $X_s$  for  $s \in S$  that generated the whole theory in the sense that every object of  $\mathcal{T}$  is a product

$$X_{s_0} \times \ldots \times X_{s_{n-1}}$$

for some word  $w = s_0 \dots s_{n-1}$  over S. We, again, suppose that projections

$$\pi_i^w \colon X_{s_0} \times \ldots \times X_{s_{n-1}} \to X_{s_i} \quad (i = 0, \ldots, n-1)$$

are chosen. And, again, instead with the above product we work with the word  $s_0 \ldots s_{n-1}$  alone. In other words, the theory  $\mathcal{N}$  which plays a central role for one-sorted theories is generalized to the following:

14.1 Notation. For every nonempty set S (of sorts) we denote by

 $S^*$ 

the category whose objects are the finite words on S, and whose morphisms from  $s_0 \ldots s_{n-1}$  to  $t_0 \ldots t_{k-1}$  are all functions  $f: k \to n$  with  $s_{f(i)} = t_i$  for all  $i = 0, \ldots, k - 1$ . In particular, for every word  $w = s_0 \ldots s_{n-1}$  we have the projections

 $\pi_i^w : s_0 \dots s_{n-1} \to s_i \quad (i = 0, \dots, n-1)$ 

given by the *i*-th injection  $1 \mapsto n$  in Set.

**14.2 Example.**  $\mathcal{N} = \{s\}^*$  provided that we identify every natural number n with the word  $ss \dots s$  of length n.

**14.3 Remark.** We know from 1.5 that  $S^*$  is an algebraic theory for  $Set^S$ , and every word w is a product of one-letter words with the projections  $\pi_0^w, \ldots, \pi_{n-1}^w$  above. We are going to identify  $Set^S$  with  $AlgS^*$ . The full embedding

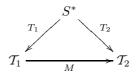

$$Y_{S^*}: (S^*)^{op} \to Set^S$$

assigns to a word  $w = s_0 \dots s_{n-1}$  the S-sorted set

$$Y_{S^*}(w)_s = \{i = 0, \dots, n-1; s_i = s\}.$$

**14.4 Definition.** Let S be a nonempty set.

- 1. A S-sorted algebraic theory is a pair  $(\mathcal{T}, T)$  where  $\mathcal{T}$  is an algebraic theory whose objects are the words over S, and T:  $S^* \to \mathcal{T}$  is a theory morphism which is the identity map on objects.
- 2. A morphism of S-sorted algebraic theories  $M: (\mathcal{T}_1, T_1) \to (\mathcal{T}_2, T_2)$  is a functor  $M: \mathcal{T}_1 \to \mathcal{T}_2$  such that  $M \cdot T_1 = T_2$

14.5 Remark. Analogously to 11.3 we have not requested that morphisms of one sorted theories preserve finite products since this simply follows from the equation  $M \cdot T_1 = T_2$ . Observe that due to that equation M is the identity map on objects.

#### 14.6 Example.

- 1. For the category *Graph* of graphs we have an *S*-sorted theory with  $S = \{v, e\}$  and  $T: S^* \to \mathcal{T}_{graph}$  is determined by Tv = v and Te = e (the theory  $\mathcal{T}_{graph}$  is described in 1.16).
- 2. Let  $\mathcal{C}$  be a small category, put  $S = \operatorname{obj} \mathcal{C}$ , and let  $E_{Th} : \mathcal{C} \to \mathcal{T}_{\mathcal{C}}$  denote the free completion of  $\mathcal{C}$  under finite products (1.14); recall from 1.15 that the objects of  $\mathcal{T}_{\mathcal{C}}$  can be viewed as words over S. Therefore, we have a unique theory morphism  $T_{\mathcal{C}} : S^* \to \mathcal{T}_{\mathcal{C}}$  which is the identity map on objects. We obtain an S-sorted theory

 $(\mathcal{T}_{\mathcal{C}}, \mathcal{T}_{\mathcal{C}})$ .

134

#### CHAPTER 14. S-SORTED ALGEBRAIC CATEGORIES

14.7 Remark. Precisely as in the one-sorted case, the functor T does not influence the concept of algebra: the category AlgT thus consists, again, of all functors  $A: T \to Set$  preserving finite products. However, the presence of T makes the category of algebras concrete over  $Set^S$ : the forgetful functor is simply

$$Alg T \colon Alg \mathcal{T} \to Set^S$$

(see 14.4). More precisely, this forgetful functor takes an algebra  $A: \mathcal{T} \to Set$  to the S-sorted set  $\langle As \rangle_{s \in S}$ , and a homomorphism  $h: A \to B$  to the S-sorted function with components  $h_s: As \to Bs$ .

**14.8 Proposition.** Let  $(\mathcal{T}, T)$  be an S-sorted algebraic theory. The forgetful functor

$$AlgT: AlgT \to Set^S$$

is faithful, algebraic and conservative. It thus preserves and reflects limits, sifted colimits, monomorphisms and regular epimorphisms.

The proof is analogous to that of 11.8.

**14.9 Remark.** The concept of one-sorted algebraic category in Chapter 11 used concrete equivalences of categories over *Set.* For *S*-sorted algebraic theories we need, analogously, concrete equivalences over  $Set^{S}$  (see 11.12).

**14.10 Definition.** A S-sorted algebraic category is a concrete category over  $Set^S$  which is concretely equivalent to  $AlgT: AlgT \to Set^S$  for an S-sorted algebraic theory  $(\mathcal{T}, T)$ .

**14.11 Proposition.** Every variety of  $\mathcal{T}$ -algebras for an S-sorted theory  $(\mathcal{T}, T)$  is an S-sorted algebraic category.

The proof is analogous to that of 11.17.

14.12 Remark. Let  $(\mathcal{T}, T)$  be an S-sorted theory.

1. The forgetful functor  $AlgT: AlgT \to Set^S$  has a left adjoint. In fact, due to 4.11 applied to  $Y_{S^*}: (S^*)^{op} \to Set^S$  we can choose a left adjoint

$$F_T \colon Set^S \to Alg \mathcal{T}$$

in such a way that the square

$$\begin{array}{c|c} (S^*)^{op} \xrightarrow{T^{op}} \mathcal{T}^{op} \\ Y_{S^*} \downarrow & & \downarrow \\ Y_{T^*} & & \downarrow \\ Set^S \xrightarrow{F_T} Alg \mathcal{T} \end{array}$$

commutes.

2.  $\mathcal{T}$ -algebras of the form  $F_T(X)$ , for X an S-sorted set, are called *free algebras*. If X is finite (1.5), they are called *finitely generated free algebras*.

**14.13 Corollary.** Let  $(\mathcal{T}, T)$  be an S-sorted theory.  $\mathcal{T}^{op}$  is equivalent to the full subcategory of Alg $\mathcal{T}$  of finitely generated free algebras.

14.14 Remark. Results about finitely presentable and perfectly presentable algebras and regular projectives generalize easily from the one-sorted case, see 11.26 - 11.33, to the S-sorted one, we leave this for the reader. Let us just stress that when working with variables, in the S-sorted case to every variable a sort is assigned. That is, the corresponding object of variables also lives in Set<sup>S</sup>.

**14.15 Theorem.** (S-sorted algebraic duality) The 2-category ALG <sup>S</sup> of S-sorted algebraic categories, concrete functors and natural transformations is biequivalent to the dual of the 2-category Th <sup>S</sup> of S-sorted algebraic theories, morphisms of S-sorted theories and natural transformations.

The proof is completely analogous to that of 11.38.

Recall from Chapter 1 the concept of an S-sorted signature, see 14.17.

**14.16 Definition.** Let  $\Sigma$  be an *S*-sorted signature.

1. A  $\Sigma$ -algebra is a pair (A, a) consisting of an S-sorted set  $A = \langle A_s \rangle_{s \in S}$  and a function a assigning to every element  $\sigma: s_0 \dots s_{n-1} \to s$  of  $\Sigma$  a mapping

$$\sigma^A \colon A_{s_0} \times \ldots \times A_{s_{n-1}} \to A_s \, .$$

(In case n = 0 we have a constant  $\sigma^A \in A_s$ .)

2.  $\Sigma$ -homomorphisms from (A, a) to (B, b) are S-sorted functions

 $f = \langle f_s \rangle$  with  $f_s \colon A_s \to B_s \ (s \in S)$ 

such that for every operation  $\sigma: s_0 \dots s_{n-1} \to s$  of  $\Sigma$  the square

$$\begin{array}{c} A_{s_0} \times \ldots \times A_{s_{n-1}} & \xrightarrow{\sigma^A} & A_s \\ f_{s_0} \times \ldots \times f_{s_{n-1}} & & & \downarrow f_s \\ & & B_{s_0} \times \ldots \times B_{s_{n-1}} & \xrightarrow{\sigma^B} & B_s \end{array}$$

commutes. This yields a concrete category

 $\Sigma$ -Alg

of  $\Sigma$ -algebras with the forgetful functor

$$U_{\Sigma} \colon \Sigma \text{-} Alg \to Set^S$$
,  $U_{\Sigma}(A, a) = A$ .

#### 14.17 Example.

1. The category of graphs has the form  $\Sigma$ -Alg for  $S = \{v, e\}$  and  $\Sigma$  consisting of two operations of arity  $e \to v$  (called  $\tau$  and  $\sigma$  in 1.11).

- 2. For  $\Sigma = \emptyset$  we have  $\Sigma$ -Alg = Set<sup>S</sup>.
- 3. For sequential automata (see 1.25) put  $S = \{s, i, o\}$  and  $\Sigma = \{\delta, \gamma, \varphi\}$  with arities  $\delta \colon si \to s, \gamma \colon s \to o$  and  $\varphi \colon s$ .
- 4. For the example of stacks 1.24 put  $S = \{s, n\}$  and  $\Sigma = \{$ succ, push, pop, top,  $0, e\}$  with the arities given in 1.24.

#### 14.18 Remark.

1. The description of a left adjoint

$$F_{\Sigma} \colon Set^{S} \to \Sigma \text{-} Alg$$

of  $U_{\Sigma}$  is completely analogous to 13.1. Given an S-sorted set X of variables, we form the smallest S-sorted set  $F_{\Sigma}X$  (of terms) such that every element  $x \in X_s$  is a term of sort s, and for every  $\sigma \in \Sigma$  of arity  $s_0 \ldots s_{n-1} \rightarrow s$  and for every n-tuple of terms  $p_0, \ldots, p_{n-1}$  of sorts  $s_0, \ldots, s_{n-1}$  respectively, we have a term  $\sigma(p_0, \ldots, p_{n-1})$  of sort s. The  $\Sigma$ -algebra structure on  $F_{\Sigma}X$  is given by the formation of terms  $\sigma(p_0, \ldots, p_{n-1})$ . This defines a functor  $F_{\Sigma}$ :  $Set^S \rightarrow \Sigma$ -Alg on object. To define it on morphisms, proceed as in 13.1.

2. We obtain, assuming a countable set of "standard variables  $x_i^s$  of sort s" for every  $s \in S$ , an S-sorted theory

 $(\mathcal{T}_{\Sigma}, T_{\Sigma})$ 

analogous to the one described in 13.2: the words  $s_0 \ldots s_{n-1}$  represent the free  $\Sigma$ -algebra  $F_{\Sigma}\{x_0^{s_0}, \ldots, x_{n-1}^{s_{n-1}}\}$ . The categories  $\Sigma$ -Alg and Alg $\mathcal{T}_{\Sigma}$  are concretely equivalent over Set<sup>S</sup>, this is analogous to 13.3.

3. Equations in the sense of 10.1 can be substituted by expressions

t = t'

where t and t' are two elements of  $F_{\Sigma}X$  of the same sort (for some finite S-sorted set X of standard variables). This is analogous to 13.9, except that in the S-sorted case the quantification of variables must be made explicit. If  $\Sigma$  is a one-sorted signature and t, t' are terms in  $F_{\Sigma}X$ , then in place of X we can take the set  $Z \subseteq X$  of all variables that appear in t or t'. An algebra satisfies t = t' independently of whether we work with  $F_{\Sigma}Z$  or  $F_{\Sigma}X$ . This is not so in S-sorted signatures, as we demonstrate below. We therefore need the following

**14.19 Definition.** Given an S-sorted signature  $\Sigma$ , by an *equation* is meant an expression

$$\forall x_0 \,\forall x_1 \dots \forall x_{n-1} \, (t=t')$$

where  $x_i$  is a variable of sort  $s_i$  (i = 0, ..., n - 1) and t, t' are elements of  $F_{\Sigma}\{x_0, ..., x_{n-1}\}$  of the same sort s. A  $\Sigma$ -algebra (A, a) satisfies the equation

provided that for every S-sorted function  $f: \{x_0, \ldots, x_{n-1}\} \to A$  the unique homomorphism  $\overline{f}: F_{\Sigma}\{x_0, \ldots, x_{n-1}\} \to (A, a)$  extending f fulfils  $\overline{f}_s(t) = \overline{f}_s(t')$ . In case n = 0 we write  $\forall \emptyset (t = t')$ .

#### 14.20 Example.

1. In the signature of graphs, see 14.17, consider variables x, x' of sort v and a variable y of sort e. The equation

$$\forall x \,\forall x' \,(x = x')$$

describes graphs on at most one vertex. Whereas

$$\forall x \,\forall x' \,\forall y \,(x = x')$$

describes all graphs that either have no edge or have just one vertex.

2. In the theory of stacks there are several equations one expects to be required. For example, if a natural number x is inserted into a stack y and then deleted, the stack does not change:

$$\forall x \,\forall y \,(\mathrm{pop}(\mathrm{push}(x, y)) = y \,.$$

Other such equations are

$$\forall x \,\forall y \,(\mathrm{top}(\mathrm{push}(x,y)) = x$$

and (due to our definition of top)

$$top(e) = 0.$$

**14.21 Example.** Let us return to Example 10.23 explaining that Birkhoff's Variety Theorem requires, in general, the use of directed unions. The example worked with  $Set^{\mathbb{N}}$  which is  $\Sigma$ -Alg for the empty  $\mathbb{N}$ -sorted signature. Let  $x_n$  and  $y_n$  be variables of sort  $n \in \mathbb{N}$ , and consider the equation quantifying  $y_n$  and all  $x_0, x_1, x_2, \ldots$ :

$$\forall y_n \,\forall x_0 \,\forall x_1 \,\forall x_2 \dots (x_n = y_n) \,.$$

Then algebras, i.e.,  $\mathbb{N}$ -sorted sets, satisfy these equations iff they lie in the category  $\mathcal{A}$ . However, infinite quantification brings us out of the finitary logic (and out of the realm of Definition 10.1).

#### 14.22 Definition.

- 1. Let  $\Sigma$  be an S-sorted signature. By an S-sorted equational category of  $\Sigma$ -algebras is meant a full subcategory of  $\Sigma$ -Alg formed by all algebras satisfying a set E of equations (in the sense of 10.1 or, equivalently, 14.18).
- 2. S-sorted equational categories are concrete categories over  $Set^{S}$  which are, for some signature  $\Sigma$ , S-sorted equational categories of  $\Sigma$ -algebras.

#### CHAPTER 14. S-SORTED ALGEBRAIC CATEGORIES

14.23 Remark. Birkhoff's Variety Theorem for S-sorted algebras states that S-sorted equational categories are precisely the full subcategories of  $\Sigma$ -Alg closed under

products,

subalgebras,

regular quotients,

and

directed unions.

If S is a finite set, the last item can be left out. The proof is completely analogous to that of 11.34: we choose  $i_0$  in such a way that given  $s \in S$  for which the sort of A is nonempty, then the sort of  $A_{i_0}$  is also nonempty.

**14.24 Example.** All one-sorted theories form a many-sorted equational category. More detailed: the category  $Th_1$  of one-sorted theories and their morphisms is an equational category of  $\Sigma$ -algebras for the following signature using  $\mathbb{N} \times \mathbb{N}$  as a set of sorts:  $\Sigma$  consists of the binary operations "composition"

 $c_{ijk}: (i,j)(j,k) \to (i,k) \quad (\text{for all } i, j, k \in \mathbb{N}),$ 

the constants expressing identity morphisms

$$e_n: (n, n) \quad (\text{for all } n \in \mathbb{N})$$

and the projections (provided by  $T: \mathcal{N} \to \mathcal{T}$ )

$$p_{n,k}: (n,k) \quad (\text{for all } k < n)$$

In fact, with every one-sorted theory  $(\mathcal{T}, T)$  associate the  $\Sigma$ -algebra  $\overline{(\mathcal{T}, T)}$  whose underlying sets are the hom-sets of  $\mathcal{T}$ 

$$\overline{(\mathcal{T},T)}_{(i,j)} = \mathcal{T}(i,j)$$

and where  $c_{ijk}$  and  $e_n$  have the obvious meaning, and the interpretation of  $p_{n,k}$ is  $T\pi_k^n$ . Every morphism  $F: (\mathcal{T}, T) \to (\mathcal{T}', T')$  of one-sorted theories defines a homomorphism of  $\Sigma$ -algebras  $\overline{F}: \overline{(\mathcal{T}, T)} \to \overline{(\mathcal{T}', T')}$  whose underlying function of sort (i, j) is the action of F at  $\mathcal{T}(i, j)$ . Then

$$\overline{-}$$
:  $Th_1 \rightarrow \Sigma - Alg$ 

is a full and faithful functor. The image of this full embedding is the equational category described by the equations expressing the fact that  $e_n$  is the identity morphism

$$c_{ijj}(f, e_j) = f$$
 and  $c_{iij}(e_i, g) = g$ 

and the associativity of composition

$$c_{ikn}(c_{ijk}(f,g),h) = c_{ijn}(f,c_{jkn}(g,h))$$

#### 14.25 Remark.

1. Another way of expressing  $Th_1$  as an equational category of many-sorted algebras uses only  $\mathbb{N}$  as the set of sorts: the underlying sets of the algebra for  $(\mathcal{T}, T)$  are then  $\mathcal{T}(n, 1)$  for  $n \in \mathbb{N}$ . Here, however, the corresponding operations need to take into account the tupling  $g(f_1, \ldots, f_n)$  of an *n*-ary operation symbol  $g \in \mathcal{T}(n, 1)$  with *n* symbols  $f_i \in \mathcal{T}(k_i, 1)$ : put

$$k = k_1 + \ldots + k_n$$

then our signature must contain "tupling" operation symbols

$$t_{k_1\ldots k_n}: k_1\ldots k_n \to k$$

(for all *n*-tuples  $k_1, \ldots, k_n$  in  $\mathbb{N}$ ). The equations describing  $Th_1$  as an equational category of  $\mathbb{N}$ -sorted algebras are then somewhat more involved.

2. The above presentation of one-sorted theories as an equational category of N-sorted algebras is closely related to the concept of clone: given a  $\Sigma$ -algebra A on a set X, the *clone* of A is the smallest set of endofunctions of many variables  $f: X^n \to X$   $(n \in \mathbb{N})$  containing all projections and all operations  $\sigma^A$  for  $\sigma \in \Sigma$  and closed under the tupling  $g(f_1, \ldots, f_n)$ . One then introduces a partial operation of (simultaneous) composition on the clone.

**14.26 Example.** All S-sorted theories form a many-sorted equational catgeory. This is completely analogous to the one-sorted case above. A trivial presentation of  $Th_S$  uses sorts  $S^* \times S^*$  (interpreted as the hom-sets of the theory). A more "clone like" presentation uses sorts  $S^* \times S$  since the hom-sets  $\mathcal{T}(w, s)$  for  $w \in S^*$  and  $s \in S$  are sufficient.

**14.27 Example.** Modules over variable rings. Here we consider pairs (R, M) where M is a right R-module as objects. Morphisms from (R, M) to (R', M') are pairs of functions (h, f) where  $h: R \to R'$  is a ring homomorphism, and  $f: M \to M'$  is a homomorphism of abelian groups satisfying

$$f(\lambda x) = h(\lambda)f(x)$$
 for all  $\lambda \in R, x \in M$ .

This is an equational category of two-sorted algebras of sorts r and m with ring operations

```
\begin{aligned} &+:rr \to r \\ &-:r \to r \\ &\times:rr \to r \\ &0,1:r \end{aligned}
```

and module operations

February 1, 2010

140

 $\begin{array}{l} \oplus \colon mm \to m \\ \oplus \colon m \to m \\ \odot \colon m \\ \ast \colon rm \to m \end{array}$ 

satisfying the equations (a) of the presentation of rings, (b) of abelian groups for  $\oplus, \ominus$  and  $\odot$  and (c) the distributive laws.

#### 14.28 Proposition.

- S-sorted algebraic categories are precisely the S-sorted equational categories. More detailed: a concrete category over Set<sup>S</sup> is S-sorted algebraic iff it is concretely equivalent to an S-sorted equational category of Σ-algebras for some signature Σ.
- 2. Uniquely transportable S-sorted algebraic categories are, up to concrete isomorphism, precisely the S-sorted equational categories.

The proof is completely analogous to that of 13.11 and 13.21.

14.29 Remark. Every S-sorted equational category is, of course, complete and cocomplete. In particular initial algebras exist in all S-sorted equational categories. In theoretical computer science these algebras are used as a formalization of "abstract data types": these are given by operations and equations and consist of elements generated by the given operations (no extra variables are used) and satisfy only the equations that are consequences of the given ones. An abstract data type is thus, precisely as initial objects should be, determined only up to isomorphism. We illustrate this on a couple of examples:

#### 14.30 Example.

- 1. Natural numbers is a one-sorted abstract data type given by a constant 0 and a unary operation s (successor). This correspond to the initial algebra of the one-sorted signature  $\Sigma = \{s, 0\}$  with arity 1 and 0, respectively. In fact, every initial  $\Sigma$ -algebra is a representation of natural numbers.
- 2. Stacks of natural numbers. Here we need the two-sorted signature  $\Sigma$  of 14.17.4. Its initial algebra does not resemble stacks because we will have formal terms such as top(e), top(top(e)), etc. However, the equational category given by the three equations of 14.20.2 has an initial algebra  $I = \langle I_n, I_s \rangle$  where  $I_n$  is the abstract data type of natural numbers (no equation involves the operation succ) and  $I_s$  consists of stacks

$$e = [], [x], [x, y], [x, y, z], \dots$$

of elements  $x, y, z, \ldots$  of  $I_n$ .

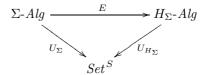

**14.31 Remark.** For one-sorted signatures we have  $\Sigma$ -Alg concretely equivalent to  $H_{\Sigma}$ -Alg, where  $H_{\Sigma}A = \coprod_{\sigma \in \Sigma} A^n$  (for  $n = \text{arity of } \sigma$ ), see 2.25. Analogously for S-sorted signatures  $\Sigma$ : define

$$H_{\Sigma} \colon Set^S \to Set^S$$

on objects  $A = \langle A_s \rangle_{s \in S}$  by setting the sort s of  $H_{\Sigma}A$  as follows; we denote by  $\Sigma_s \subseteq \Sigma$  the set of all symbols of output sort s and put

$$(H_{\Sigma}A)_s = \prod_{\sigma \in \Sigma_s} A_{s_0} \times \ldots \times A_{s_{n-1}}$$

for the arity  $s_0 \ldots s_{n-1} \to s$  of  $\sigma$ . Then there is a concrete equivalence

assigning to every  $\Sigma$ -algebra (A, a) the  $H_{\Sigma}$ -algebra  $(A, \overline{a})$  where the coproduct components of

$$\overline{a}_s \colon \prod_{\sigma \in \Sigma_s} A_{s_0} \times \ldots \times A_{s_{n-1}} \to A_s$$

are the given operations  $\sigma^A$ .

**14.32 Proposition.** Every finitary endofunctor H of Set<sup>S</sup> is a quotient of a polynomial functor  $H_{\Sigma}$  for some S-sorted signature  $\Sigma$ . Moreover, the concrete category H-Alg is concretely isomorphic to an equational category of  $\Sigma$ -algebras.

**Proof.** For the first statement, the argument in 12.15 using Yoneda Lemma generalizes without a problem: define an S-sorted signature  $\Sigma$  whose operations  $\sigma$  of (an arbitrary) arity  $s_0 \ldots s_{n-1} \to s$  are precisely the elements of sort s in HX, where the S-sorted set X is given by

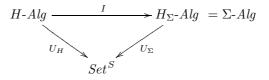

$$X_t = \{i = 0, \dots, n-1; s_i = t\}$$
 for all  $t \in S$ .

Then define  $\alpha \colon H_{\Sigma} \to H$  by taking such an operation symbol  $\sigma$  and putting

$$\alpha_Z(\sigma(f)) = (Hf)_s(\sigma)$$

for all S-sorted function f from the above set X into Z. For the second statement, the only difference to the proof of 13.23 is that in

For the second statement, the only difference to the proof of 13.23 is that in the S-sorted case we must also check that I(H-Alg) is closed in  $\Sigma$ -Alg under directed unions. This follows from the commutativity of the diagram

since  $U_H$  preserves sifted colimits and  $U_{\Sigma}$  reflects them (see 12.17.3).

#### 14.33 Remark.

1. The converse implication of Theorem 12.15 does not generalize to the S-sorted case: a quotient of a polynomial functor on  $Set^S$  need not be finitary.

A simple example can be presented in  $Set^{\mathbb{N}}$ : start with the constant functor of value 2 = 1 + 1 (the *S*-sorted set having two elements in every sort). This functor is clearly polynomial. Let *H* be the quotient with HX = 1 whenever all sorts of *X* are nonempty, else, HX = 2. This functor does not preserve the filtered colimit of all finitely presentable subobjects of 1.

2. For finite sets S of sorts Theorem 12.15 fully generalizes: finitary endofuctors of  $Set^S$  are precisely the quotients of polynomial functors. In fact, the proof of 12.15 easily modifies: in part (b) of the implication  $3 \Rightarrow 1$ choose the S-sorted set Z' in such a way that for every sort s we have  $Z'_s \neq \emptyset$  iff  $C_s \neq \emptyset$ ; since  $\mathcal{D}$  is filtered and S is finite, this choice is clearly possible. Then, again,  $c'_d \cdot i'$  is a split monomorphism.

#### Historical Remarks for Chapter 14

Historical comments on S-sorted algebras have been mentioned already at the end of Chapter 1. For a short introduction to applications of S-sorted algebras see [96].

#### CHAPTER 14. S-SORTED ALGEBRAIC CATEGORIES

# Part III: Special topics

"Modern algebra also enables one to reinterpret the results of classical algebra, giving them far greater unity and generality."

G. Birkhoff and S. Mac Lane, A Survey of Modern Algebra, Macmillan Co. New York 1965.

. PART III: SPECIAL TOPICS

## Chapter 15

# Morita equivalence

In this chapter we study the problem of the presentation of an algebraic category by different algebraic theories. This is inspired by the classical work of Kiiti Morita who in 1950's studied this problem for the categories R-Mod of left modules over a ring R. He completely characterized pairs of rings R and S such that R-Mod and S-Mod are equivalent categories; such rings are nowadays called *Morita equivalent*. We will recall the results of Morita below, and we will show in which way they generalize from R-Mod to  $Alg\mathcal{T}$  where  $\mathcal{T}$  is an algebraic theory.

We begin with a particularly simple example.

**15.1 Example.** In 1.4, we described a one-sorted algebraic theory  $\mathcal{N}$  of Set:  $\mathcal{N}$  is the full subcategory of  $Set^{op}$  whose objects are the natural numbers. Here is another one-sorted theory of Set:  $\mathcal{T}_2$  is the full subcategory of  $Set^{op}$  whose objects are the even natural numbers  $0, 2, 4, 6, \ldots, \mathcal{T}_2$  obviously has finite products. Observe that  $\mathcal{T}_2$  is not idempotent-complete (consider the constant functions  $2 \to 2$ ) and that  $\mathcal{N}$  is an idempotent function of  $\mathcal{T}_2$ : for every natural number n we can find an idempotent function  $f: 2n \to 2n$  with precisely n fixed points. Then n is obtained by splitting f. Following 6.14 and 8.12,  $Alg\mathcal{T}_2 \simeq Alg\mathcal{N} \simeq Set$ .

In fact, we can repeat the previous argument for every natural number k > 0. In this way we get a family  $\mathcal{T}_k$ ,  $k = 1, 2, \ldots$  of one-sorted algebraic theory of *Set* (with  $\mathcal{T}_1 = \mathcal{N}$ ). We will prove later that, up to equivalence, there is no other one-sorted algebraic theory of *Set*.

Clearly, if  $\mathcal{T}$  and  $\mathcal{T}'$  are algebraic theories and if there is an equivalence  $\mathcal{T} \simeq \mathcal{T}'$ , then  $Alg \mathcal{T}$  and  $Alg \mathcal{T}'$  are equivalent categories. The previous example shows that the converse is not true.

**15.2 Definition.** Two algebraic theories  $\mathcal{T}$  and  $\mathcal{T}'$  are called *Morita equivalent* if the corresponding categories  $Alg\mathcal{T}$  and  $Alg\mathcal{T}'$  are equivalent.

From 6.14 and 8.12. we already know a simple characterization of Morita equivalent algebraic theories: two theories are Morita equivalent iff they have

equivalent idempotent completions. In case of S-sorted algebraic categories a much sharper result can be proved. Before doing so, let us recall the classical result of Morita.

**15.3 Example.** Let R be a unitary ring (not necessarily commutative) and denote by R-Mod for the category of left R-modules. There are two basic constructions:

- 1. Matrix ring  $R^{[k]}$ . This is the ring of all  $k \times k$  matrices over R with the usual addition, multiplication, and unit matrix. This ring  $R^{[k]}$  is Morita equivalent to R for every k > 0, i.e., the category  $R^{[k]}$ -Mod is equivalent to R-Mod.
- 2. Idempotent modification uRu. Let u be an idempotent element of R, uu = u, and let uRu be the ring of all elements  $x \in R$  with ux = x = xu with the binary operation inherited from R and the neutral element u. This ring is Morita equivalent to R whenever u is pseudoinvertible, i.e., eum = 1 for some elements e and m of R.

Morita's original result is that the two operations above are sufficient: if a ring S is Morita equivalent to R, i.e., R-Mod and S-Mod are equivalent categories, then S is isomorphic to the ring  $uR^{[k]}u$  for some pseudoinvertible idempotent  $k \times k$  matrix u.

We now generalize Morita constructions to one-sorted algebraic theories and mention the S-sorted case later.

**15.4 Definition.** Let  $(\mathcal{T}, T)$  be a one-sorted algebraic theory.

- 1. The matrix theory  $(\mathcal{T}^{[k]}, T^{[k]})$ , for  $k = 1, 2, 3, \ldots$  is the one-sorted algebraic theory whose morphisms  $f: p \to q$  are precisely the morphisms  $f: kp \to kq$  of  $\mathcal{T}$ ; composition and identity morphisms are defined as in  $\mathcal{T}$ . And  $T^{[k]}: \mathcal{N} \to \mathcal{T}^{[k]}$  takes the projection  $\pi_i^n$  to the morphism of  $\mathcal{T}(kn, k)$ which is the *i*-th chosen projection of  $kn = k \times \ldots \times k$  in  $\mathcal{T}$ .
- 2. Let  $u: 1 \to 1$  be an idempotent morphism  $(u \cdot u = u)$ . We call u pseudoinvertible provided that there exist morphisms  $m: 1 \to k$  and  $e: k \to 1$  such that

$$e \cdot u^k \cdot m = \mathrm{id}_1$$
.

The *idempotent modification* of  $(\mathcal{T}, T)$  is the theory  $(u\mathcal{T}u, u\mathcal{T}u)$  whose morphisms  $f: p \to q$  are precisely the morphisms of  $\mathcal{T}$  satisfying  $f \cdot u^p = f = u^q \cdot f$ . The composition is defined as in  $\mathcal{T}$ , the identity morphism on p is  $u^p$ . The functor  $u\mathcal{T}u: \mathcal{N} \to u\mathcal{T}u$  is the codomain restriction of T.

#### 15.5 Remark.

1. Both  $\mathcal{T}^{[k]}$  and  $u\mathcal{T}u$  are well defined. In fact,  $\mathcal{T}^{[k]}$  has finite products with  $p = 1 \times \ldots \times 1$ : the *i*-th projection is obtained from the *i*-th projection in  $\mathcal{T}$  of  $kp = k \times \ldots \times k$ . Also  $u\mathcal{T}u$  has finite products with  $p = 1 \times \ldots \times 1$ : the *i*-projection  $\pi_i \colon p \to 1$  of  $\mathcal{T}$  yields a morphism  $u \cdot \pi_i \colon p \to 1$  of  $u\mathcal{T}u$   $(i = 1, \ldots, k)$  and these morphisms form a product  $p = 1 \times \ldots \times 1$  in  $u\mathcal{T}u$ .

#### CHAPTER 15. MORITA EQUIVALENCE

2. Observe that in the definition of Morita equivalence the categories  $Alg \mathcal{T}$  are treated as abstract categories: the forgetful functor does not play a role here.

**15.6 Theorem.** Let  $(\mathcal{T}, T)$  be a one-sorted algebraic theory.

1. The matrix theories  $\mathcal{T}^{[k]}$  are Morita equivalent to  $\mathcal{T}$  for all k > 0,

and

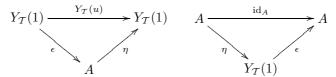

2. the idempotent modifications uTu are Morita equivalent to T for all pseudoinvertible idempotents u.

**Proof.** 1: Matrix theory  $\mathcal{T}^{[k]}$ . We have a full and faithful functor  $\mathcal{T}^{[k]} \to \mathcal{T}$  defined on objects by  $n \mapsto nk$  and on morphisms as the identity mapping. Every objects of  $\mathcal{T}$  is a retract of an object coming from  $\mathcal{T}^{[k]}$ : in fact, for every n consider the diagonal morphism  $\Delta: n \to nk = n \times \ldots \times n$ . Consequently,  $\mathcal{T}$  and  $\mathcal{T}^{[k]}$  have the same idempotent completion. Thus, by 8.12, they are Morita equivalent.

2: Idempotent modification  $u\mathcal{T}u$ . Here we consider  $\mathcal{T}$  as a full subcategory of  $(Alg\mathcal{T})^{op}$  via the Yoneda embedding (1.12)

$$Y_{\mathcal{T}} \colon \mathcal{T} \to (Alg \, \mathcal{T})^{op}$$

Following 8.3, the idempotent  $Y_{\mathcal{T}}(u) \colon Y_{\mathcal{T}}(1) \to Y_{\mathcal{T}}(1)$  has a splitting in  $(Alg \mathcal{T})^{op}$ , say

Consider also the subcategory  $\mathcal{T}_A$  of  $(Alg\mathcal{T})^{op}$  of all powers  $A^n, n \in \mathbb{N}$ . Together with the obvious functor  $T_A \colon \mathcal{N} \to \mathcal{T}_A$  this is a one-sorted algebraic theory, and it is Morita equivalent to  $\mathcal{T}$ . In fact, every object of  $\mathcal{T}$  is a retract of one in  $\mathcal{T}_A$  and vice-versa – this clearly implies that  $\mathcal{T}$  and  $\mathcal{T}_A$  have a joint idempotent completion (obtained by splitting their idempotents in  $(Alg\mathcal{T})^{op}$ ). Indeed, since A is a retract of  $Y_{\mathcal{T}}(1)$ ,  $A^p$  is a retract of  $Y_{\mathcal{T}}(p)$ . Conversely, consider  $m: 1 \to n$ and  $e: n \to 1$  in  $\mathcal{T}$  such that  $e \cdot u^n \cdot m = \operatorname{id}_1$  as in 15.4.2. Then  $Y_{\mathcal{T}}(1)$  is a retract of  $A^n$  via  $\epsilon^n \cdot Y_{\mathcal{T}}(m) \colon Y_{\mathcal{T}}(1) \to A^n$  and  $Y_{\mathcal{T}}(e) \cdot \eta^n \colon A^n \to Y_{\mathcal{T}}(1)$ , and then  $Y_{\mathcal{T}}(p)$ is a retract of  $A^{np}$ .

To complete the proof, we construct an equivalence functor  $\bar{Y}: u\mathcal{T}u \to \mathcal{T}_A$ . On objects it is defined by  $\bar{Y}(p) = A^p$ , and on morphisms  $f: p \to q$  by

$$\begin{array}{c|c}
A^p & \xrightarrow{\bar{Y}f} & A^q \\
 & & \uparrow \\
\eta^p & & \uparrow \\
\gamma_T(p) & & \uparrow \\
Y_{\mathcal{T}}(f) & Y_{\mathcal{T}}(q)
\end{array}$$

in  $(Alg\mathcal{T})^{op}$ . Observe that  $\bar{Y}(\mathrm{id}_p) = \mathrm{id}_{A^p}$  because  $\epsilon \cdot \eta = \mathrm{id}_A$ . Now, we check the equation

$$Y_{\mathcal{T}}(f) = \eta^q \cdot \bar{Y}(f) \cdot \epsilon^p \qquad [15.1]$$

Indeed:

$$Y_{\mathcal{T}}(f) = Y_{\mathcal{T}}(u)^q \cdot Y_{\mathcal{T}}(f) \cdot Y_{\mathcal{T}}(u)^p = \eta^q \cdot \epsilon^q \cdot Y_{\mathcal{T}}(f) \cdot \eta^p \cdot \epsilon^p = \eta^q \cdot \bar{Y}(f) \cdot \epsilon^p.$$

From equation [15.1] since  $\epsilon^p$  is a (split) epimorphism and  $\eta^q$  is is a (split) monomorphism, we deduce that  $\bar{Y}$  preserves composition (because  $Y_T$  does), and that  $\bar{Y}$  is faithful (because  $Y_T$  is). Since  $\bar{Y}$  is surjective on objects, it remains to show that it is full: consider  $h: A^p \to A^q$  in  $(Alg T)^{op}$ , we define  $k = \eta^q \cdot h \cdot \epsilon^p: Y_T(p) \to Y_T(q)$ . Since  $Y_T$  is full, there is a  $f: p \to q$  in T such that  $Y_T(f) = k$ . Now:

$$\bar{Y}(f) = \epsilon^q \cdot Y_T(f) \cdot \eta^p = \epsilon^q \cdot \eta^q \cdot h \cdot \epsilon^p \cdot \eta^p = h.$$

It remains to check that f is in  $u\mathcal{T}u$ :

$$Y_{\mathcal{T}}(f) \cdot Y_{\mathcal{T}}(u^p) = \eta^q \cdot h \cdot \epsilon^p \cdot \eta^p \cdot \epsilon^p = \eta^q \cdot h \cdot \epsilon^p = k = Y_{\mathcal{T}}(f)$$

and then  $f \cdot u^p = f$  because  $Y_T$  is faithful; analogously,  $u^q \cdot f = f$ .

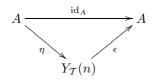

**15.7 Theorem.** For two one-sorted algebraic theories  $(\mathcal{T}, T)$  and  $(\mathcal{S}, S)$  the following conditions are equivalent:

- 1. S is Morita equivalent to T;
- 2. S is, as a category, equivalent to an idempotent modification  $u\mathcal{T}^{[k]}u$  of a matrix theory of  $\mathcal{T}$  for some pseudoinvertible idempotent u of  $\mathcal{T}^{[k]}$ .

**Proof.** Consider an equivalence functor

$$E: Alg \mathcal{S} \to Alg \mathcal{T}$$

and the Yoneda embeddings  $Y_{\mathcal{S}} \colon \mathcal{S}^{op} \to Alg\mathcal{S}, Y_{\mathcal{T}} \colon \mathcal{T}^{op} \to Alg\mathcal{T}$  (recall, from 1.13, that  $Y_{\mathcal{S}}$  and  $Y_{\mathcal{T}}$  preserve finite coproducts). Since  $Y_{\mathcal{S}}(1)$  is perfectly presentable in  $Alg\mathcal{S}$  (5.5), then  $A = E(Y_{\mathcal{S}}(1))$  is perfectly presentable in  $Alg\mathcal{T}$ , therefore, due to (5.14) it is a retract of  $Y_{\mathcal{T}}(n)$  for some n in  $\mathbb{N}$ :

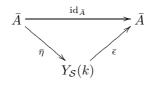

There exists a unique  $u: n \to n$  in  $\mathcal{T}$  such that  $Y_{\mathcal{T}}(u) = \eta \cdot \epsilon$ , and such a u is an idempotent. We consider u as an idempotent on 1 in  $\mathcal{T}^{[n]}$  and prove that uis pseudoinvertible there. For this, choose an  $\mathcal{S}$ -algebra  $\overline{A}$  and an isomorphism

February 1, 2010

150

#### CHAPTER 15. MORITA EQUIVALENCE

 $i: Y_{\mathcal{T}}(n) \to E\overline{A}$ . Since E is an equivalence functor,  $\overline{A}$  is perfectly presentable, thus it is a retract of  $Y_{\mathcal{S}}(k)$  for some  $k \in \mathbb{N}$ :

Consider now the composites

$$Y_{\mathcal{T}}(n) \xrightarrow{i} E\bar{A} \xrightarrow{E\bar{\eta}} EY_{\mathcal{S}}(k) \simeq kA \xrightarrow{k\eta} kY_{\mathcal{T}}(n) \simeq Y_{\mathcal{T}}(nk)$$

and

$$Y_{\mathcal{T}}(nk) \simeq kY_{\mathcal{T}}(n) \xrightarrow{k\epsilon} kA \simeq EY_{\mathcal{S}}(k) \xrightarrow{E\bar{\epsilon}} E\bar{A} \xrightarrow{i^{-1}} Y_{\mathcal{T}}(n)$$

then there exist unique morphisms  $e: nk \to n$  and  $m: n \to nk$  in  $\mathcal{T}$  which  $Y_{\mathcal{T}}$  maps on the above composites. One immediately checks that  $Y_{\mathcal{T}}(e \cdot u^k \cdot m) = \mathrm{id}$ , that is  $e \cdot u^k \cdot m = \mathrm{id}$ . Thus u is pseudoinvertible in  $\mathcal{T}^{[n]}$ .

To complete the proof, we construct an equivalence functor  $\overline{E}: S \to u \mathcal{T}^{[n]} u$ . It is the identity map on objects. If  $f: p \to q$  is a morphism in  $S, \overline{E}f$  is the unique morphism  $np \to nq$  in  $\mathcal{T}$  such that

$$\begin{array}{c|c} qY_{\mathcal{T}}(n) \simeq Y_{\mathcal{T}}(nq) \xrightarrow{Y_{\mathcal{T}}(Ef)} & Y_{\mathcal{T}}(np) \simeq pY_{\mathcal{T}}(n) \\ & & & & \\ q\epsilon & & & & \\ q \epsilon & & & & \\ qA \simeq E(Y_{\mathcal{S}}(q)) \xrightarrow{} & E(Y_{\mathcal{S}}(p)) \simeq pA \end{array}$$

commutes. Using once again  $Y_{\mathcal{T}}(u) = \eta \cdot \epsilon$  and the faithfulness of  $Y_{\mathcal{T}}$ , one easily checks that  $u^p \cdot \overline{E}f \cdot u^q = \overline{E}f$ , so that  $\overline{E}f$  is a morphism  $p \to q$  in  $u\mathcal{T}^{[n]}u$ . The proof that  $\overline{E}$  is a well defined, full and faithful functor is analogous to that in Theorem 15.6 and is left to the reader.

**15.8 Example.** All one-sorted theories of *Set.* These are, up to equivalence of categories, precisely the theories  $\mathcal{T}_k$  of 15.1. More precisely, for every k consider the matrix theory  $(\mathcal{N}^{[k]}, \mathrm{Id}^{[k]})$  (which, as a category, is clearly equivalent to  $\mathcal{T}_k$  of 15.1). Given an idempotent  $u: 1 \to 1$  of  $\mathcal{N}^{[k]}$ , then the function  $u: k \to k$  in *Set* is pseudoinvertible iff it is invertible, thus  $u = \mathrm{id}$ . Consequently, there are no other one-sorted theories of *Set*.

**15.9 Example.** Let R be a ring with unit. Following 11.22, we can describe a one-sorted theory  $(\mathcal{T}_R, \mathcal{T}_R)$  of R- $Mod : \mathcal{T}_R$  is essentially the full subcategory of R- $Mod^{op}$  of the finitely generated free R-modules  $R^n$   $(n \in \mathbb{N})$ . That is, the morphisms in  $\mathcal{T}_R(n, 1)$  are the homomorphisms from R to  $R^n$ , and  $\mathcal{T}_R$  assigns to  $\pi_i^n$  the *i*-th injection of  $R + \ldots + R$ . Every one-sorted algebraic theory of R-Modis equivalent to  $\mathcal{T}_S$  for some ring S which is Morita equivalent to R. Indeed, the two constructions of 15.3 fully correspond to the two constructions of 15.4:

- 1.  $\mathcal{T}_{(R^{[k]})}$  is equivalent to  $(\mathcal{T}_R)^{[k]}$ ;
- 2. given an idempotent element  $u \in R$ , the corresponding module homomorphism  $\bar{u}: R \to R$  with  $\bar{u}(x) = ux$  fulfils: uRu is equivalent to  $\bar{u}(\mathcal{T}_R)\bar{u}$ .

**15.10 Example.** For every monoid M, consider the category M-Set (cf. 13.15). Two monoids M and  $\overline{M}$  are called *Morita equivalent* if M-Set and  $\overline{M}$ -Set are equivalent categories. Here we need just one operation on monoids: if  $\overline{M}$  is Morita equivalent to M, then  $\overline{M}$  is isomorphic to an idempotent modification uMu for some pseudoinvertible idempotent u of M.

In contrast with the situation of 15.9, M-Set has, in general, many one-sorted theories not connected to any Morita equivalent monoid. (This is true even for  $M = \{*\}$ , since M-Set = Set has infinitely many theories which are not equivalent as categories, see 15.1.) However, all unary theories of M-Set have the form which correspond to Morita equivalent monoids. By a unary theory we mean a one-sorted theory  $(\mathcal{T}, T)$  for which the category  $\mathcal{T}$  is a free finite product completion (see 1.14) of the endomorphism monoid  $\mathcal{T}(1,1)$ . The category of Msets has an obvious unary theory with  $\mathcal{T}(1,1) = M$ . Its morphism from n to 1 are the homomorphisms from M to the free M-set  $M + M + \ldots + M$  on n generators (so that the category  $\mathcal{T}$  is, essentially, the full subcategory of  $(M-Set)^{op}$  on the M-sets  $M + M + \ldots + M$ ). Consequently, for every Morita equivalent monoid  $\overline{M}$  we have a unary theory  $\mathcal{T}_{[\overline{M}]}$  for the category *M-Set*. And these are, up to categorical equivalence, all unary theories. In fact, let  $\mathcal{T}$  be a unary theory with Alg  $\mathcal{T}$  equivalent to M-Set. For the monoid  $\overline{M} = \mathcal{T}(T,T)$ , there is an obvious categorical equivalence between  $Alg\mathcal{T}$  and  $\overline{M}$ -Set : every  $\overline{M}$ -set  $A: \overline{M} \to Set$ has an essentially unique extension to a  $\mathcal{T}$ -algebra  $A': \mathcal{T} \to Set$ , and (-)' is the desired equivalence functor. Therefore,  $\overline{M}$  is Morita equivalent to M, and  $\mathcal{T}$  is equivalent to  $\mathcal{T}_{[\overline{M}]}$ .

#### 15.11 Remark.

- 1. The above examples demonstrate that Theorems 15.6 and 15.7 yield a much more practical characterization than just stating that two theories have the same idempotent completion.
- 2. For S-sorted theories  $(\mathcal{T}, T)$  the result is quite analogous. Given a collection

$$u = (u_s)_{s \in S}$$

with  $u_s: s \to s$  an idempotent, let us call *u* pseudoinvertible provided that for each  $s \in S$  there exists a word  $t_1 \dots t_k$  and morphisms

$$m_s: s \to t_1 \dots t_k$$
 and  $e_s: t_1 \dots t_k \to s$ 

in  $\mathcal{T}$  with

$$e_s \cdot (u_{t_1} \times \ldots \times u_{t_k}) \cdot m_s = \mathrm{id}_s$$

Then  $(u\mathcal{T}u, u\mathcal{T}u)$  is the S-sorted theory whose morphisms  $f: s_1 \ldots s_n \to r$ are those morphisms of  $\mathcal{T}$  with  $f \cdot (u_{s_1} \times \ldots \times u_{s_n}) = f = u_r \cdot f$ . And the functor  $u\mathcal{T}u$  is a codomain restriction of T.

#### CHAPTER 15. MORITA EQUIVALENCE

For two S-sorted theories  $(\mathcal{T}, T)$  and  $(\mathcal{T}', T')$  we have that  $\mathcal{T}'$  is Morita equivalent to  $\mathcal{T}$  iff it is (as a category) equivalent to  $u\mathcal{T}u$  for some pseudoinvertible collection  $u = (u_s)_{s \in S}$ . The proof is analogous to that of 15.6 and 15.7, the reader can find it in [13].

**15.12 Remark.** Another approach to classical Morita theory for rings is based on the following result, due to Eilenberg and Watts (see [21], Theorem 2.3): Let R, S be unitary rings, and let M be an R-S-bimodule. The formation of tensor products  $M \otimes_S X$  for S-modules X defines a functor

$$M \otimes_S (-) \colon S\text{-}Mod \to R\text{-}Mod$$

which preserves colimits (because it is a left adjoint). In fact, the assignment

$$M \mapsto M \otimes_S (-)$$

induces a bijection between isomorphism classes of R-S-bimodules and isomorphism classes of colimit preserving functors.

Using Eilenberg-Watts Theorem one can prove that R and S are Morita equivalent iff there exist bimodules M, N and bimodule isomorphisms

$$M \otimes_S N \simeq R$$
 and  $N \otimes_R M \simeq S$ 

These facts are easy to generalize to (abstract) algebraic theories. The generalization of Eilenberg-Watts Theorem is given by the following lemma.

**15.13 Lemma.** Let  $\mathcal{T}$  be an algebraic theory. The functor

$$Y_{\mathcal{T}}: \mathcal{T}^{op} \to Alg \mathcal{T}$$

is a free completion of  $\mathcal{T}^{\,op}$  conservative with respect to finite coproducts. This means that

1. Alg  $\mathcal{T}$  is cocomplete and  $Y_{\mathcal{T}}$  preserves finite coproducts

and

2. for every functor  $F: \mathcal{T}^{op} \to \mathcal{B}$  preserving finite coproducts, where  $\mathcal{B}$  is a cocomplete category, there exists an essentially unique functor  $F^*: Alg \mathcal{T} \to \mathcal{B}$  preserving colimits with F naturally isomorphic to  $F^* \cdot Y_{\mathcal{T}}$ .

**Proof.** This follows from 1.13 and 4.15.

15.14 Definition. Let  $\mathcal{T}, \mathcal{S}$  be algebraic theories. A *bimodule* 

$$M\colon \mathcal{T} \Rightarrow \mathcal{S}$$

is a functor  $M: \mathcal{T}^{op} \to Alg \mathcal{S}$  preserving finite coproducts.

#### 15.15 Remark.

February 1, 2010 153

- 1. The functor  $Y_{\mathcal{T}}: \mathcal{T}^{op} \to Alg\mathcal{T}$  is a bimodule  $\mathcal{T} \Rightarrow \mathcal{T}$ . More generally, every morphism of theories  $\mathcal{T} \to \mathcal{S}$  induces a bimodule  $\mathcal{T} \Rightarrow \mathcal{S}$  by composition with  $Y_{\mathcal{S}}$ .
- 2. Every bimodule M has, by 15.13, an extension  $M^* \colon Alg \mathcal{T} \to Alg \mathcal{S}$  preserving colimits. These are, up to natural isomorphism, the only colimit-preserving functors between algebraic categories.
- 3. Bimodules compose: given bimodules  $M: \mathcal{T} \Rightarrow \mathcal{S}$  and  $N: \mathcal{S} \Rightarrow \mathcal{R}$  we define  $N \circ M: \mathcal{T} \Rightarrow \mathcal{R}$  by  $N^* \cdot M$ . This composition is associative up to isomorphism and  $Y_{\mathcal{S}} \circ M \simeq M \simeq M \circ Y_{\mathcal{T}}$ . (In other words, the 2-category  $Th_{bim}$  defined below is in fact a *bicategory* in the sense of J. Bénabou [24].)

#### 15.16 Definition.

1. The 2-category  $Th_{bim}$  has

objects: algebraic theories,

1-cells: bimodules,

2-cells: natural transformations.

2. The 2-category  $ALG_{colim}$  has

objects: algebraic categories,

1-cells: colimit preserving functors,

2-cells: natural transformations.

#### 15.17 Corollary.

1. The 2-categories  $Th_{bim}$  and  $ALG_{colim}$  are biequivalent. In fact, the assignment

 $M \colon \mathcal{T} \Rightarrow \mathcal{S} \mapsto M^* \colon Alg \mathcal{T} \to Alg \mathcal{S}$ 

of 15.15 extends to a biequivalence  $Th_{bim} \simeq ALG_{colim}$ .

2. Two algebraic theories  $\mathcal{T}$  and  $\mathcal{S}$  are Morita equivalent if and only if there exist bimodules  $M: \mathcal{T} \Rightarrow \mathcal{S}$  and  $N: \mathcal{S} \Rightarrow \mathcal{T}$  such that  $N \circ M \simeq Y_{\mathcal{T}}$  and  $M \circ N \simeq Y_{\mathcal{S}}$ .

In fact,  $Th_{bim} \rightarrow ALG_{colim}$  is an equivalence on hom-categories by 15.13. The rest of the proof is obvious.

#### Historical Remarks for Chapter 15

The classical results concerning equivalences for categories of modules were proved by K. Morita in [73]. Thirty years later J.J. Dukarm proved a generalization to one-sorted algebraic theories in [39].

For one-sorted theories an approach to Morita equivalence via bimodules is due to F. Borceux and E. M. Vitale [29]. The many-sorted version of Morita

#### CHAPTER 15. MORITA EQUIVALENCE

equivalence in 15.11 is due to J. Adámek, M. Sobral and L. Sousa [13]. Example 15.10 is due to B. Banaschewski, see [16].

The Eilenberg-Watts theorem quoted in 15.12 was independently proved by S. Eilenberg in [42] and C. E. Watts in [95]. An exhaustive treatment of Morita theory for rings in terms of bimodules appears in the monograph of H. Bass [21].

CHAPTER 15. MORITA EQUIVALENCE

## Chapter 16

# Free exact categories

We know that every algebraic category is an exact category having enough regular projective objects (see 3.18 and 5.15). In the present chapter, we study *free exact completions* and prove that every algebraic category is a free exact completion of its full subcategory of all regular projectives. This will be used in the next chapter to characterize algebraic categories among exact categories, and to describe all finitary localizations of algebraic categories.

The trouble with regular projective objects in an algebraic category is that they are not closed under finite limits. Luckily they have weak finite limits. Recall that *weak limits* are defined as limits except that the uniqueness of the factorization is not requested (see 16.7). The main point is that the universal property of a free exact completion is based on *left covering functors*. These are functors which play, for categories with weak finite limits, the role that functors preserving finite limits play for finitely complete categories.

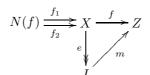

We will be concerned with regular epimorphisms (3.4) in an exact category (3.16). For the comfort of the reader, we start by listing some of their (easy but) important properties. In diagrams, regular epimorphisms are denoted by

#### **16.1 Lemma.** Let $\mathcal{A}$ be an exact category.

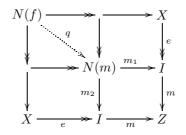

- 1. Any morphism factorizes as a regular epimorphism followed by a monomorphism.
- 2. Consider a morphism  $f: X \to Z$ . The following conditions are equivalent:
  - (a) f is a regular epimorphism;
  - (b) f is a strong epimorphism;
  - (c) f is an extremal epimorphism.

**Proof.** 1: Consider a morphism  $f: X \to Z$  and its factorization through the

coequalizer of its kernel pair

We have to prove that m is a monomorphism. For this, consider the following diagram, where each square is a pullback

Since in  $\mathcal{A}$  regular epimorphisms are pullback stable, the diagonal q is an epimorphism. Now,  $m_1 \cdot q = e \cdot f_1 = e \cdot f_2 = m_2 \cdot q$ , so that  $m_1 = m_2$ . This means that m is a monomorphism.

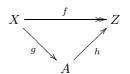

2: a  $\Rightarrow$  b: Let u, v and m be morphisms such that  $v \cdot f = m \cdot u$ . If f is the coequalizer of a pair (x, y), and m a monomorphism, then u also coequalizes x and y.

b  $\Rightarrow$  c: If  $f = m \cdot u$  with m a monomorphism, we can write  $v \cdot f = m \cdot u$  with v = id. By condition (b) m is a split epimorphism, but a monomorphism which is also a split epimorphism is an isomorphism.

 $c \Rightarrow a$ : Just take a regular epi-mono factorization  $f = m \cdot e$  (which exists by 1.); if condition (c) holds, then m is an isomorphism and therefore f is a regular epimorphism.

**16.2 Corollary.** Let  $\mathcal{A}$  be an exact category.

- 1. The factorization stated in Lemma 16.1.1 is essentially unique;
- 2. The composite of two regular epimorphisms is a regular epimorphism;
- 3. If the triangle

commutes and f is a regular epimorphism, then h is a regular epimorphism;

4. If a morphism is a regular epimorphism and a monomorphism, then it is an isomorphism.

#### CHAPTER 16. FREE EXACT CATEGORIES

In fact, everything follows easily from condition 2.b of Lemma 16.1.

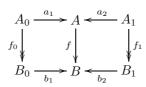

**16.3 Lemma.** Every exact category has the following properties:

- 1. The product of two regular epimorphisms is a regular epimorphism;
- 2. Consider the following diagram

$$\begin{array}{c|c} A_0 & \xrightarrow{a_1} & A_1 \\ \hline f_0 & & & \downarrow \\ f_0 & & & \downarrow \\ B_0 & \xrightarrow{b_1} & B_1 \end{array}$$

with  $f_1 \cdot a_i = b_i \cdot f_0$  for i = 1, 2. If  $f_0$  is a regular epimorphism and  $f_1$  is a monomorphism, then the unique extension to the equalizers is a regular epimorphism;

3. Consider the following commutative diagram

If  $f_0$  and  $f_1$  are regular epimorphisms and f is a monomorphism, then the extension of f from the pullback of  $a_1$  and  $a_2$  to the pullback of  $b_1$  and  $b_2$  is a regular epimorphism.

**Proof.** 1: Observe that  $f \times id$  is the pullback of f along the suitable projection, and the same holds for  $id \times g$ . Now  $f \times g = (f \times id) \cdot (id \times g)$ . 2: Since  $f_1$  is a monomorphism, the pullback of the equalizer of  $(b_1, b_2)$  along

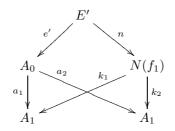

2: Since  $f_1$  is a monomorphism, the purpack of the equalizer of  $(a_1, a_2)$  along  $f_0$  is the equalizer of  $(a_1, a_2)$ .

3: This follows from 1. and 2., using the usual construction of pullbacks via products and equalizers.  $\hfill \Box$ 

For the sake of generality, let us point out that in 16.1, 16.2 and 16.3 we do not need that in  $\mathcal{A}$  equivalence relations are effective.

**16.4 Remark.** In 16.3.2 if  $f_1$  is any morphism (not necessarily a monomorphism) it is no longer true that the pullback of an equalizer  $e: E \to B_0$  of  $(b_1, b_2)$  along  $f_0$  is an equalizer of  $(a_1, a_2)$ . What remains true (in any category with finite limits) is the following fact: let  $e': E' \to A_0$  be a pullback of e along  $f_0$ , let  $k_1, k_2: N(f_1) \rightrightarrows A_1$  be a kernel pair of  $f_1$ , and  $n: E' \to N(f_1)$  the unique morphism such that  $k_i \cdot n = a_i \cdot e'$  (i = 1, 2). Then the following is a limit

diagram

We will use this fact in the proof of Theorem 16.24.

From Propositions 3.18 and 5.15 we know that an algebraic category is an exact category having enough regular projective objects. In fact, each algebra is a regular quotient of a regular projective algebra. In the following we study categories having enough regular projectives; we introduce the concept of a regular projective cover for a subcategory of regular projectives in case there is "enough of them".

**16.5 Definition.** Let  $\mathcal{A}$  be a category. A *regular projective cover* of  $\mathcal{A}$  is a full and faithful functor  $I: \mathcal{P} \to \mathcal{A}$  such that

- 1. for every object P of  $\mathcal{P}$ , IP is regular projective in  $\mathcal{A}$ ;
- 2. for every object A of  $\mathcal{A}$ , there exists an object P in  $\mathcal{P}$  and a regular epimorphism  $P \to A$  (we write P instead of IP and we call  $P \to A$  a  $\mathcal{P}$ -cover of A).

**16.6 Definition.** A functor is *exact* if it preserves finite limits and regular epimorphisms.

The present chapter is devoted to the study of exact functors defined on an exact category  $\mathcal{A}$  having a regular projective cover  $\mathcal{P} \to \mathcal{A}$ . First of all, observe that regular projective objects are not closed under finite limits, so that we cannot hope that  $\mathcal{P}$  inherits finite limits from  $\mathcal{A}$ . Nevertheless, a "trace" of finite limits remains in  $\mathcal{P}$ . In fact,  $\mathcal{P}$  has weak finite limits.

**16.7 Definition.** A weak limit of a diagram  $D: \mathcal{D} \to \mathcal{A}$  is a cone  $p_X: W \to DX$  ( $X \in obj \mathcal{D}$ ) such that for every other cone  $a_X: A \to DX$  there exists a morphism  $a: A \to W$  such that  $p_X \cdot a = a_X$  for all X.

Observe that, unlike limits, weak limits are very much "non-unique". For example, any nonempty set is a weak terminal object in the category *Set*.

**16.8 Lemma.** If  $\mathcal{P} \to \mathcal{A}$  is a regular projective cover of a finitely complete category  $\mathcal{A}$ , then  $\mathcal{P}$  has weak finite limits.

**Proof.** Consider a finite diagram  $D: \mathcal{D} \to \mathcal{P}$ . If

$$\langle \pi_X \colon L \to DX \rangle_{X \in \mathcal{D}}$$

February 1, 2010

160

is a limit of D in  $\mathcal{A}$ , then we choose a  $\mathcal{P}$ -cover  $l: P \to L$ . The resulting cone

$$\langle \pi_X \cdot l \colon P \to DX \rangle_{X \in \mathcal{D}}$$

is a weak limit of D in  $\mathcal{P}$ .

In the situation of the previous lemma, apply an exact functor  $G: \mathcal{A} \to \mathcal{B}$ . Since G preserves finite limits, the factorization of the cone

$$\langle G(\pi_X \cdot l) \colon GP \to G(DX) \rangle_{X \in \mathcal{D}}$$

through the limit in  $\mathcal{B}$  is  $Gl: GP \to GL$ , which is a regular epimorphism because G is exact.

We can formalize this property in the following definition.

**16.9 Definition.** Let  $\mathcal{B}$  be an exact category and let  $\mathcal{P}$  be a category with weak finite limits. A functor  $F: \mathcal{P} \to \mathcal{B}$  is *left covering* if, for any finite diagram  $D: \mathcal{D} \to \mathcal{P}$  with weak limit W, the canonical comparison morphism  $FW \to \lim F \cdot D$  is a regular epimorphism.

**16.10 Remark.** To avoid any ambiguity in the previous definition, let us point out that if the comparison  $w: FW \to \lim F \cdot D$  is a regular epimorphism for a certain weak limit W of D, then the comparison  $w': FW' \to \lim F \cdot D$  is a regular epimorphism for any other weak limit W' of D. This follows from Corollary 16.2 because w factorizes through w'.

#### 16.11 Example.

- 1. If a finite diagram  $D: \mathcal{D} \to \mathcal{A}$  has a limit L, then the weak limits of D are precisely the objects W such that L is a retract of W. Therefore any functor preserving finite limits is left covering.
- 2. If  $\mathcal{P} \to \mathcal{A}$  is a regular projective cover of an exact category  $\mathcal{A}$ , then it is a left covering functor.
- 3. The composition of a left covering functor with an exact functor is a left covering functor.

**16.12 Example.** Let  $\mathcal{P}$  be a category with weak finite limits, and consider the (possibly illegitimate) functor category  $[\mathcal{P}^{op}, Set]$ . The canonical Yoneda embedding  $Y_{\mathcal{P}^{op}} : \mathcal{P} \to [\mathcal{P}^{op}, Set]$  is a left covering functor.

**Proof.** Consider a finite diagram  $D: \mathcal{D} \to \mathcal{P}$  in  $\mathcal{P}$ , a weak limit W of D and a limit L of  $Y_{\mathcal{P}^{op}} \cdot D$ . The canonical comparison  $\tau: Y_{\mathcal{P}^{op}}(W) \to L$  is a regular epimorphism whenever, for all  $Z \in \mathcal{P}$ ,  $\tau_Z: Y_{\mathcal{P}^{op}}(W)(Z) \to LZ$  is surjective. Since the limit L is computed pointwise in *Set*, an element of LZ is a cone from Z to  $\mathcal{L}$ , so that the surjectivity of  $\tau_Z$  is just the weak universal property of W.

February 1, 2010

16.13 Remark. In the main result of this chapter (16.24) we show that an exact category with enough regular projective objects is a free exact completion of any of its regular projective covers. This is one of the results that request working with the left covering property (instead of the seemingly more natural condition of preservation of weak finite limits). In fact, the basic example 16.11.2 would not be true otherwise. This can be illustrated by the category of rings: the inclusion of the full subcategory  $\mathcal{P}$  of all regular projective rings does not preserve weak finite limits. For example, the ring  $\mathbb{Z}$  of integers is a weak terminal object in  $\mathcal{P}$ , but it is not a weak terminal object in  $\mathcal{A}$  because the unique morphism from  $\mathbb{Z}$  to the one-element ring does not have a section.

A remarkable fact about left covering functors is that they classify exact functors. Before stating this in a precise way, see 16.24, we need some facts about left covering functors and pseudoequivalences. A pseudoequivalence is defined "almost" as an equivalence relation, but (a) using a weak pullback instead of a pullback to express the transitivity, and (b) without the assumption that the graph be jointly monic.

**16.14 Definition.** Let  $\mathcal{P}$  be a category with weak pullbacks. A *pseudoequivalence* is a parallel pair

$$X' \xrightarrow[x_2]{x_1} X$$

which is

- 1. reflexive, i.e., there exists  $r: X \to X'$  such that  $x_1 \cdot r = id_X = x_2 \cdot r$ ,
- 2. symmetric, i.e., there exists  $s \colon X' \to X'$  such that  $x_1 \cdot s = x_2$  and  $x_2 \cdot s = x_1$ ,

and

3. transitive, i.e., in an arbitrary weak pullback

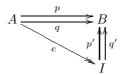

there exists  $t: P \to X'$  such that  $x_1 \cdot t = x_1 \cdot x'_1$  and  $x_2 \cdot t = x_2 \cdot x'_2$ . The morphism t is called a *transitivity morphism* of  $x_1$  and  $x_2$ .

#### 16.15 Remark.

- 1. Observe that the existence of a transitivity morphism of  $x_1$  and  $x_2$  does not depend on the choice of a weak pullback of  $x_1$  and  $x_2$ .
- 2. Recall that a regular factorization of a morphism is a factorization as a regular epimorphism followed by a monomorphism. In a category with

binary products, we speak about regular factorization of a parallel pair  $p, q: A \rightrightarrows B$ . What we mean is a factorization of (p, q) as in the following diagram, where e is a regular epimorphism and (p', q') is a jointly monomorphic parallel pair

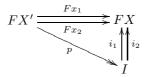

obtained by a regular factorization of  $\langle p,q \rangle \colon A \to B \times B$ . Since jointly monomorphic parallel pairs are also called relations, we call (p',q') the relation induced by (p,q).

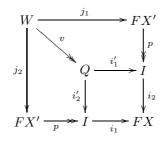

3. If  $\mathcal{P}$  has finite limits, then equivalence relations are precisely those parallel pairs which are, at the same time, relations and pseudoequivalences. The next result, which is the main link between pseudoequivalences and left covering functors, shows that any pseudoequivalence in an exact category is a composition of an equivalence relation with a regular epimorphism. (The converse is not true: if we compose an equivalence relation with a regular epimorphism in general we do not obtain a pseudoequivalence. Consider the category of rings, the unique equivalence relation on the oneelement ring 0, and the unique morphism  $\mathbb{Z} \to 0$ . The parallel pair  $\mathbb{Z} \rightrightarrows 0$ is not reflexive, because there are no morphisms from 0 to  $\mathbb{Z}$ .)

**16.16 Lemma.** Let  $F: \mathcal{P} \to \mathcal{B}$  be a left covering functor. For every pseudoequivalence  $x_1, x_2: X' \rightrightarrows X$  in  $\mathcal{P}$ , the relation in  $\mathcal{B}$  induced by  $(Fx_1, Fx_2)$  is an equivalence relation.

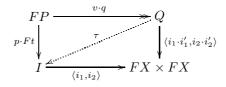

**Proof.** Consider a regular factorization in  $\mathcal{B}$ 

Since the reflexivity and transitivity are obvious, we only check the transitivity of  $(i_1, i_2)$ . The pullback of  $i_1 \cdot p$  and  $i_2 \cdot p$  factorizes through the pullback of  $i_1$  and  $i_2$ , and the factorization, v, is a regular epimorphism (because p is a regular epimorphism and  $\mathcal{B}$  is an exact category):

Consider also a transitivity morphism  $t: P \to X'$  of  $(x_1, x_2)$  as in Definition 16.14. Since  $F: \mathcal{P} \to \mathcal{B}$  is left covering, the factorization  $q: FP \to W$  such that  $j_1 \cdot q = Fx'_1$  and  $j_2 \cdot q = Fx'_2$  is a regular epimorphism. Finally, we have the following commutative diagram

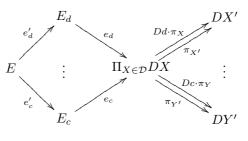

Since  $v \cdot q$  is a regular epimorphism and  $\langle i_1, i_2 \rangle$  is a monomorphism, there exists  $\tau : Q \to I$  such that  $\langle i_1, i_2 \rangle \cdot \tau = \langle i_1 \cdot i'_1, i_2 \cdot i'_2 \rangle$ . This implies that  $(i_1, i_2)$  is transitive.

16.17 Remark. Generalizing the fact that functors preserve finite limits iff they preserve finite products and equalizers, we are going to prove the same for left coverings. We use the phrase "left covering with respect to weak finite products" for the restriction of 16.9 to discrete categories  $\mathcal{D}$ . Observe that this is equivalent to being left covering with respect to weak binary products and weak terminal objects. Analogously, we use "left covering with respect to equalizers".

**16.18 Lemma.** A functor  $F: \mathcal{P} \to \mathcal{B}$ , where  $\mathcal{P}$  has weak finite limits and  $\mathcal{B}$  is exact, is left covering if and only if it is left covering with respect to weak finite products and weak equalizers.

**Proof.** 1. Using Lemma 16.3 and working by induction, one extends the left covering character of F to joint equalizers of parallel *n*-tuples, and then to multiple pullbacks.

2. Consider a finite diagram  $D: \mathcal{D} \to \mathcal{P}$ . We can construct a weak limit of D using a weak product  $\prod_{X \in \mathcal{D}} DX$ , weak equalizers  $E_d$ , one for each morphism  $d: X \to X'$  in  $\mathcal{D}$ , and a weak multiple pullback E as in the following diagram

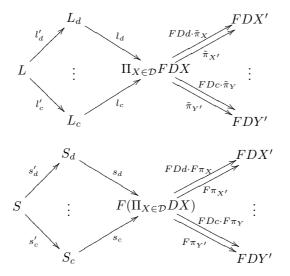

February 1, 2010

164

#### CHAPTER 16. FREE EXACT CATEGORIES

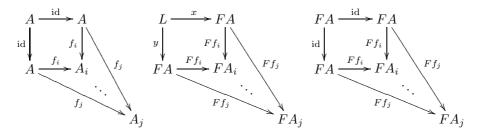

Perform the same constructions in  $\mathcal{B}$  to get limits as in the following diagrams

By assumption, the canonical factorization  $q_d \colon FE_d \to S_d$  is a regular epimorphism. By Lemma 16.3, this gives rise to a regular epimorphism  $q \colon Q \to S$ , where Q is the multiple pullback of the  $Fe_d$ . By part 1., the canonical factorization  $t \colon FE \to Q$  is a regular epimorphism. Finally, a diagram chase shows that the pullback of  $l_d \cdot l'_d$  along the canonical factorization  $p \colon F(\prod_{X \in \mathcal{D}} DX) \to \prod_{X \in \mathcal{D}} FDX$  is  $s_d \cdot s'_d$ . By part 1., p is a regular epimorphism, so that we get a regular epimorphism  $p' \colon S \to L$ . The regular epimorphism  $p' \cdot q \cdot t \colon FE \to Q \to S \to L$  shows that F is left covering.

**16.19 Lemma.** A left covering functor  $F : \mathcal{P} \to \mathcal{B}$  preserves finite jointly monomorphic sources.

**Proof.** A family of morphisms  $(f_i \colon A \to A_i)_{i \in I}$  is jointly monomorphic if and only if the span formed by  $id_A$ ,  $id_A$  is a limit of the corresponding diagram:

Now apply F and consider the canonical factorization  $q: FA \to L$ , where L is a limit in  $\mathcal{B}$  of the corresponding diagram. By assumption, q is a regular epimorphism. It is also a monomorphism, because  $x \cdot q = \mathrm{id}$ , and so it is an isomorphism. This implies that  $\mathrm{id}_{FA}$ ,  $\mathrm{id}_{FA}$  is a limit, thus the family  $(Ff_i: FA \to FA_i)_{i \in I}$  is jointly monomorphic.

**16.20 Lemma.** Consider a functor  $F \colon \mathcal{P} \to \mathcal{B}$ . Assume that  $\mathcal{P}$  has finite limits and  $\mathcal{B}$  is exact. Then F is left covering if and only if it preserves finite limits.

**Proof.** One implication is clear, see 16.11.1. Thus, let us assume that F is left covering and consider a finite nonempty diagram  $D: \mathcal{D} \to \mathcal{P}$ . Let  $(\pi_X: L \to DX)_{X \in \mathcal{D}}$  be a limit of D and  $(\tilde{\pi}_X: \tilde{L} \to FDX)_{X \in \mathcal{D}}$  a limit of  $F \cdot D$ . Since the family  $(\pi_X)_{X \in \mathcal{D}}$  is jointly monomorphic, by Lemma 16.19 also the family  $(F\pi_X)_{X \in \mathcal{D}}$  is monomorphic. This implies that the canonical factorization  $p: FL \to \tilde{L}$  is a monomorphism. But it is a regular epimorphism by assumption, so that it is an isomorphism.

The argument for the terminal object T is different. In  $\mathcal{P}$ , the product of T with itself is T with the identity morphisms as projections. Then the canonical factorization  $FT \rightarrow FT \times FT$  is a (regular) epimorphism. This implies that the two projections  $\pi_1, \pi_2 \colon FT \times FT \rightrightarrows FT$  are equal. But the pair  $(\pi_1, \pi_2)$  is the kernel pair of the unique morphism q to the terminal object of  $\mathcal{B}$ , so that q is a monomorphism. Since F is left covering, q is a regular epimorphism, thus an isomorphism.

Let us point out that in 16.16 and 16.18 we do not need to assume that equivalence relations are effective in  $\mathcal{B}$ . Moreover, if in Definition 16.9 we replace regular epimorphism by strong epimorphism, then 16.19 and 16.20 hold for all categories  $\mathcal{B}$  with finite limits.

**16.21 Definition.** Let  $\mathcal{P}$  be a category with weak finite limits. A *free exact* completion of  $\mathcal{P}$  is an exact category  $\mathcal{P}_{ex}$  with a left covering functor

$$\Gamma \colon \mathcal{P} \to \mathcal{P}_{es}$$

such that for every exact category  $\mathcal{B}$  and for every left covering functor  $F: \mathcal{P} \to \mathcal{B}$ , there exists an essentially unique exact functor  $\hat{F}: \mathcal{P}_{ex} \to \mathcal{B}$  with  $\hat{F} \cdot \Gamma$  naturally isomorphic to F.

Note that, since a free exact completion is defined via a universal property, it is determined uniquely up to equivalence.

**16.22 Remark.** Since the composition of the left covering functor  $\Gamma: \mathcal{P} \to \mathcal{P}_{ex}$  with an exact functor  $\mathcal{P}_{ex} \to \mathcal{B}$  clearly gives a left covering functor  $\mathcal{P} \to \mathcal{B}$ , the previous universal property can be restated in the following way: Composition with  $\Gamma$  induces an equivalence functor

$$-\cdot \Gamma \colon Ex[\mathcal{P}_{ex},\mathcal{B}] \to Lco[\mathcal{P},\mathcal{B}]$$

where  $Ex[\mathcal{P}_{ex}, \mathcal{B}]$  is the category of exact functors from  $\mathcal{P}_{ex}$  to  $\mathcal{B}$  and natural transformations, and  $Lco[\mathcal{P}, \mathcal{B}]$  is the category of left covering functors from  $\mathcal{P}$  to  $\mathcal{B}$  and natural transformations.

16.23 Remark. In order to prepare the proof of Theorem 16.24, let us explain how an exact category with enough regular projective objects can be reconstructed using any of its regular projective covers. Let  $\mathcal{P} \to \mathcal{A}$  be a regular

February 1, 2010

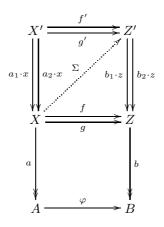

166

## CHAPTER 16. FREE EXACT CATEGORIES

projective cover of an exact category  $\mathcal{A}$ . Fix an object A in  $\mathcal{A}$  and consider a  $\mathcal{P}$ -cover  $a: X \to A$ , its kernel pair  $a_1, a_2: N(a) \rightrightarrows X$ , and again a  $\mathcal{P}$ -cover  $x: X' \to N(a)$ . In the resulting diagram

$$X' \xrightarrow[a_2 \cdot x]{a_2 \cdot x} X \xrightarrow{a} A$$

the left-hand part is a pseudoequivalence in  $\mathcal{P}$  (not in  $\mathcal{A}$ !) and A is its coequalizer. Consider a morphism  $\varphi \colon A \to B$  in  $\mathcal{A}$  and the following diagram

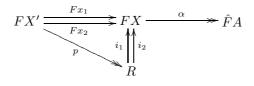

Using the regular projectivity of X and X' and the universal property of the kernel pair of b, we get a pair (f', f) such that  $\varphi \cdot a = b \cdot f$  and  $f \cdot a_i \cdot x = b_i \cdot z \cdot f'$  for i = 1, 2. Conversely, a pair (f', f) such that  $f \cdot a_i \cdot x = b_i \cdot z \cdot f'$  for i = 1, 2 induces a unique extension to the quotient. Moreover, two such pairs (f', f) and (g', g) have the same extension if and only if there is a morphism  $\Sigma \colon X \to Z'$  such that  $b_1 \cdot z \cdot \Sigma = f$  and  $b_2 \cdot z \cdot \Sigma = g$ .

**16.24 Theorem.** Let  $I: \mathcal{P} \to \mathcal{A}$  be a regular projective cover of an exact category  $\mathcal{A}$ . Then  $\mathcal{A}$  is a free exact completion of  $\mathcal{P}$ .

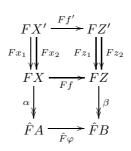

**Proof.** 1. Extension of a left covering functor  $F: \mathcal{P} \to \mathcal{B}$  to a functor  $\hat{F}: \mathcal{A} \to \mathcal{B}$ . To define  $\hat{F}$  on objects  $A \in \mathcal{A}$ , construct the coequalizer

$$X' \xrightarrow{x_1 = a_1 \cdot x} X \xrightarrow{a} A$$

as in 16.23. By 16.16, the relation  $(i_1, i_2)$  induced by  $Fx_1, Fx_2: FX' \rightrightarrows FX$ in  $\mathcal{B}$  is an equivalence relation. Since  $\mathcal{B}$  is exact, we can define  $\widehat{F}A$  to be a coequalizer of  $(i_1, i_2)$ 

Let now  $\varphi \colon A \to B$  be a morphism in  $\mathcal{A}$ . We can construct a pair  $f \colon X \to Z$ ,  $f' \colon X' \to Z'$  as in 16.23 and define  $\hat{F}\varphi$  to be the unique extension to the quotients as in the following diagram

The discussion in 16.23 shows that this definition does not depend on the choice of the pair f, f'. The preservation of composition and identity morphisms by  $\hat{F}$ comes from the uniqueness of the extension to the quotients. It is clear that  $\hat{F} \cdot I$  is naturally isomorphic to F and that a different choice of  $\mathcal{P}$ -covers X and X' for a given object  $A \in \mathcal{A}$  produces a functor naturally isomorphic to  $\hat{F}$ . 2.  $\hat{F}$  is the essentially unique exact functor such that  $\hat{F} \cdot I$  is naturally isomorphic

2. F is the essentially unique exact functor such that  $F \cdot I$  is naturally isomorphic to F. Indeed, using once again the notations of 16.23,  $(\hat{F}a_1, \hat{F}a_2)$  is the kernel pair of  $\hat{F}a$ , and  $\hat{F}x$  and  $\hat{F}a$  are regular epimorphisms:

$$FX' \simeq \hat{F}X' \xrightarrow{\hat{F}x} \hat{F}N(a) \xrightarrow{\hat{F}a_1} \hat{F}X \simeq FX \xrightarrow{\hat{F}a} \hat{F}A$$

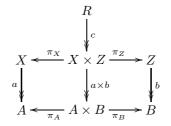

This implies that  $\hat{F}A$  is necessarily a coequalizer of  $(Fx_1, Fx_2)$ . In a similar way one shows that  $\hat{F}$  is uniquely determined on morphisms.

3. The extension  $\hat{F}: \mathcal{A} \to \mathcal{B}$  preserves finite limits. In fact, it is sufficient to show that  $\hat{F}$  is left covering with respect to the terminal object, binary products and equalizers of pairs, see Lemma 16.18 and Lemma 16.20.

3a. Products: let A and B be objects in A. Working as in 16.23 we get coequalizers

$$X' \xrightarrow{x_1} X \xrightarrow{a} A$$
 and  $Z' \xrightarrow{z_1} Z \xrightarrow{b} B$ 

Consider the following diagram, where both lines are products in  $\mathcal{A}$  and  $c \colon R \to X \times Z$  is a  $\mathcal{P}$ -cover

By 16.3.1  $a \times b$  is a regular epimorphism, so that  $(a \times b) \cdot c \colon R \to A \times B$  is a  $\mathcal{P}$ -cover. Moreover, by 16.8  $(R, \pi_X \cdot c, \pi_Z \cdot c)$  is a weak product of X and Z in

## CHAPTER 16. FREE EXACT CATEGORIES

 $\mathcal{P}$ . Applying  $\hat{F}$ , we have the following diagram in  $\mathcal{B}$ 

$$\begin{array}{c|c} FX \xleftarrow{F(\pi_X \cdot c)} FR \xleftarrow{F(\pi_Z \cdot c)} FZ \\ & & \swarrow \\ \alpha & & & & \swarrow \\ \hat{F}A \xleftarrow{\gamma} & & & & & \downarrow \\ \hat{F}A \xleftarrow{\hat{F}\pi_A} \hat{F}(A \times B) \xrightarrow{\hat{F}\pi_B} \hat{F}B \end{array}$$

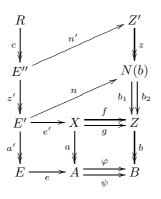

from which we get the following commutative square

$$\begin{array}{c|c} FR & \stackrel{\langle F(\pi_X \cdot c), F(\pi_Z \cdot c) \rangle}{\longrightarrow} FX \times FZ \\ \gamma & & \downarrow \\ \hat{F}(A \times B) \xrightarrow[\langle \hat{F}\pi_A, \hat{F}\pi_B \rangle]{} & \hat{F}A \times \hat{F}B \end{array}$$

The top morphism is a regular epimorphism because F is left covering, and the right-hand morphism is a regular epimorphism by 16.3.3, so that the bottom morphism also is a regular epimorphism, as requested. 3b. Equalizers: let

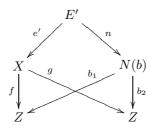

$$E \xrightarrow{e} A \xrightarrow{\varphi} B$$

be an equalizer in  $\mathcal{A}$ . The idea is once again to construct a  $\mathcal{P}$ -cover of E using  $\mathcal{P}$ -covers of A and B. For that, consider the following diagram:

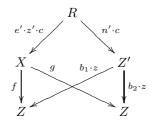

where  $a: X \to A$  and  $b: Z \to B$  are  $\mathcal{P}$ -covers, E' is a pullback of a and e, the equations  $b \cdot f = \varphi \cdot a$  and  $b \cdot g = \psi \cdot a$  hold, N(b) is a kernel pair of b, n is the unique morphism such that  $b_1 \cdot n = f \cdot e'$  and  $b_2 \cdot n = g \cdot e'$ , E'' is a pullback of z and n, and  $z: Z' \to N(b)$  and  $c: R \to E''$  are  $\mathcal{P}$ -covers. From 16.4 we know

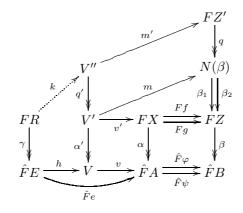

that the following is a limit diagram in  ${\mathcal A}$ 

Clearly, it remains a limit diagram if we paste it with the pullback E'' and, by 16.8, we get a weak limit in  $\mathcal{P}$  by covering it with  $c \colon R \to E''$ 

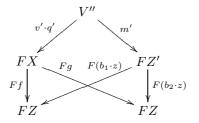

Consider the following diagram in  $\mathcal{B}$ :

where V is an equalizer of  $\hat{F}\varphi$  and  $\hat{F}\psi$ ,  $\alpha \colon FX \to \hat{F}A$ ,  $\beta \colon FZ \to \hat{F}B$  and  $\gamma \colon FR \to \hat{F}E$  are the coequalizers defining  $\hat{F}A$ ,  $\hat{F}B$  and  $\hat{F}E$  (as explained in the first part of the proof), V' is a pullback of  $\alpha$  and v,  $N(\beta)$  is a kernel pair of  $\beta$ , m is the unique morphism such that  $\beta_1 \cdot m = Ff \cdot v'$  and  $\beta_2 \cdot m = Fg \cdot v', q$  is the unique morphism such that  $\beta_i \cdot q = F(b_i \cdot z)$  (i = 1, 2), V'' is a pullback of q and m, and  $h \colon \hat{F}E \to V$  is the unique morphism such that  $v \cdot h = \hat{F}e$ . We have to prove that h is a regular epimorphism. By 16.4 the following is a limit

diagram:

Since F is left covering, the unique morphism  $k: FR \to V''$  such that  $m' \cdot k = F(n' \cdot c)$  and  $v' \cdot q' \cdot k = F(e' \cdot z' \cdot c)$  is a regular epimorphism. As  $\mathcal{B}$  is exact and F is left covering, by 16.16  $(\beta_1, \beta_2)$  is the equivalence relation induced by  $(z_1, z_2)$ , so that q is a regular epimorphism, and then q' also is a regular epimorphism. Since  $\alpha'$  also is a regular epimorphism, it remains to check that  $\alpha' \cdot q' \cdot k = h \cdot \gamma$ . By composing with the monomorphism v, this is an easy diagram chasing.

3c. Terminal object: let  $1_{\mathcal{A}}$  and  $1_{\mathcal{B}}$  be terminal objects of  $\mathcal{A}$  and  $\mathcal{B}$ , and  $T \to 1_{\mathcal{A}}$  a  $\mathcal{P}$ -cover. Applying  $\hat{F}$  we get a commutative diagram

Since T is weak terminal in  $\mathcal{P}$  and F is left covering,  $FT \to 1_{\mathcal{B}}$  is a regular epimorphism. Therefore,  $\hat{F}1_{\mathcal{A}} \to 1_{\mathcal{B}}$  also is a regular epimorphism.

4. The extension  $\hat{F}: \mathcal{A} \to \mathcal{B}$  preserves regular epimorphisms. This is obvious: if  $\varphi: \mathcal{A} \to \mathcal{B}$  is a regular epimorphism in  $\mathcal{A}$  and  $a: X \to \mathcal{A}$  is a  $\mathcal{P}$ -cover, we can choose as a  $\mathcal{P}$ -cover of B the morphism  $\varphi \cdot a: X \to B$ . Applying  $\hat{F}$  we get a commutative diagram

$$\begin{array}{c|c} FX & \xrightarrow{\mathrm{Id}} FX \\ \alpha & & & & \\ \widehat{F}A & \xrightarrow{} \widehat{F}\varphi & \widehat{F}B \end{array}$$

which shows that  $\hat{F}\varphi$  is a regular epimorphism.

## 16.25 Corollary.

- 1. Let  $\mathcal{A}$  and  $\mathcal{B}$  be exact categories and  $I: \mathcal{P} \to \mathcal{A}$  a regular projective cover. Given exact functors  $G, G': \mathcal{A} \rightrightarrows \mathcal{B}$  with  $G \cdot I \simeq G' \cdot I$ , then  $G \simeq G'$ .
- Let A and A' be exact categories, P → A a regular projective cover of A and P' → A' one of A'. Any equivalence P ≃ P' extends to an equivalence A ≃ A'.

**16.26 Remark.** For later use, let us point out a simple consequence of the previous theorem. Consider the free exact completion  $I: \mathcal{P} \to \mathcal{A}$  as in 16.24 and

February 1, 2010

a functor  $K: \mathcal{A} \to \mathcal{B}$ , with  $\mathcal{B}$  exact. If K preserves coequalizers of equivalence relations and  $K \cdot \Gamma$  is left covering, then K is exact.

**16.27 Corollary.** Let  $\mathcal{A}$  be an algebraic category and  $\mathcal{P}$  its full subcategory of regular projective objects. The inclusion  $I: \mathcal{P} \to \mathcal{A}$  is a free exact completion of  $\mathcal{P}$ .

In fact, this follows from Theorem 16.24 because  $\mathcal{A}$  is exact (see 3.18) and  $\mathcal{P}$  is a projective cover of  $\mathcal{A}$  (see 5.15).

## Historical Remarks for Chapter 16

Following a suggestion of A. Joyal, the exact completion of a category with finite limits was presented by A. Carboni and R. Celia Magno in [33]. The more general approach working with categories with weak finite limits is due to A. Carboni and E. M. Vitale [34].

The connection between the exact completion and the homotopy category of topological spaces (see 17.4) was established by M. Gran and E. M. Vitale in [46].

## Chapter 17

# Exact completion and reflexive-coequalizer completion

The present chapter is devoted to elementary constructions of two free completions described in Chapters 16 and 7, respectively, in a different manner: a free exact completion (of categories with weak finite limits) and a free reflexivecoequalizer completion (of categories with finite coproducts). The reader may decide to skip this chapter without losing the connection to Chapter 18.

In Chapter 16 we have seen that if  $I: \mathcal{P} \to \mathcal{A}$  is a regular projective cover of an exact category  $\mathcal{A}$ , then  $\mathcal{P}$  has weak finite limits and I is a free exact completion of  $\mathcal{P}$ . We complete here the study of the exact completion showing that for any category  $\mathcal{P}$  with weak finite limits it is possible to construct a free exact completion  $\Gamma: \mathcal{P} \to \mathcal{P}_{ex}$ . Moreover,  $\Gamma$  is a regular projective cover of  $\mathcal{P}_{ex}$ . The following construction of  $\mathcal{P}_{ex}$  is suggested by 16.23.

17.1 Definition. Given a category  $\mathcal{P}$  with weak finite limits, we define the category  $\mathcal{P}_{ex}$  as follows:

- 1. Objects of  $\mathcal{P}_{ex}$  are pseudoequivalences  $x_1, x_2 \colon X' \rightrightarrows X$  in  $\mathcal{P}$  (we sometimes denote such an object by X/X').
- 2. A premorphism in  $\mathcal{P}_{ex}$  is a pair of morphisms (f', f) as in the diagram

$$\begin{array}{c} X' \xrightarrow{f'} Z' \\ x_1 \\ \downarrow \\ x_2 \\ X \xrightarrow{f} Z \end{array}$$

such that  $f \cdot x_1 = z_1 \cdot f'$  and  $f \cdot x_2 = z_2 \cdot f'$ .

- 3. A morphism in  $\mathcal{P}_{ex}$  is an equivalence class  $[f', f]: X/X' \to Z/Z'$  of premorphisms, where two parallel premorphisms (f', f) and (g', g) are equivalent if there exists a morphism  $\Sigma: X \to Z'$  such that  $z_1 \cdot \Sigma = f$  and  $z_2 \cdot \Sigma = g$ .
- 4. Composition and identities are obvious.

**17.2 Notation.** We denote by  $\Gamma: \mathcal{P} \to \mathcal{P}_{ex}$  the embedding of  $\mathcal{P}$  into  $\mathcal{P}_{ex}$  assigning to a morphism  $f: X \to Z$  the following morphism

## 17.3 Remark.

- 1. The fact that the above relation among premorphisms is an equivalence relation can be proved (step by step) using the assumption that the codomain  $z_1, z_2: Z' \rightrightarrows Z$  is a pseudoequivalence. Observe also that the class of (f', f) depends on f only (compose f with a reflexivity morphism of  $(z_1, z_2)$  to show that (f', f) and (f'', f) are equivalent); for this reason, we often write [f] instead of [f', f].
- 2. The fact that composition is well-defined is obvious.
- 3.  $\Gamma$  is a full and faithful functor. This is easy to verify.
- 4. Observe that if  $\mathcal{P}$  is small (or locally small), then  $\mathcal{P}_{ex}$  also is small (or locally small, respectively).

**17.4 Remark.** The above equivalence relation among premorphisms in  $\mathcal{P}_{ex}$  can be thought of as a kind of "homotopy" relation. And in fact, this is the case in a particular example: let X be a topological space and  $X^{[0,1]}$  the space of continuous maps from the interval [0,1] to X; the evaluation maps  $ev_0, ev_1: X^{[0,1]} \rightrightarrows X$ constitute a pseudoequivalence. This gives rise to a functor  $\mathcal{E}: \mathbf{Top} \to \mathbf{Top}_{ex}$ . Now two continuous maps  $f, g: X \to Z$  are homotopic in the usual sense precisely when  $\mathcal{E}(f)$  and  $\mathcal{E}(g)$  are equivalent in the sense of Definition 17.1. More precisely,  $\mathcal{E}$  factorizes through the homotopy category, and the factorization  $\mathcal{E}': \mathbf{HTop} \to \mathbf{Top}_{ex}$  is full and faithful (and left covering).

We are going to prove that the above category  $\mathcal{P}_{ex}$  is exact and the functor  $\Gamma: \mathcal{P} \to \mathcal{P}_{ex}$  is a regular projective cover. For this, it is useful to have an equivalent description of  $\mathcal{P}_{ex}$  as a full subcategory of the functor category  $[\mathcal{P}^{op}, Set].$ 

**17.5 Lemma.** Let  $\mathcal{P}$  be a category with weak finite limits, and let

$$Y_{\mathcal{P}^{op}} \colon \mathcal{P} \to [\mathcal{P}^{op}, Set]$$

be the Yoneda embedding. The following properties of a functor  $A: \mathcal{P}^{op} \to Set$  are equivalent:

February 1, 2010

174

1. A is a regular quotient of a representable object modulo a pseudoequivalence in  $\mathcal{P}$ , i.e., there exists a pseudoequivalence  $x_1, x_2 \colon X' \rightrightarrows X$  in  $\mathcal{P}$  and a coequalizer

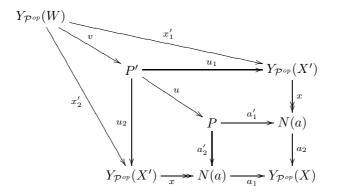

$$Y_{\mathcal{P}^{op}}(X') \xrightarrow{x_1} Y_{\mathcal{P}^{op}}(X) \longrightarrow A$$

in  $[\mathcal{P}^{op}, Set];$ 

2. A is a regular quotient of a representable object modulo a regular epimorphism  $a: Y_{\mathcal{P}^{op}}(X) \to A$  such that N(a), the domain of a kernel pair of a, is also a regular quotient of a representable object:

$$Y_{\mathcal{P}^{op}}(X') \xrightarrow{x} N(a) \xrightarrow{a_1} Y_{\mathcal{P}^{op}}(X) \xrightarrow{a} A \qquad (for some X' in \mathcal{P}).$$

**Proof.** Consider the diagram displayed in 2. Since a is the coequalizer of  $(a_1 \cdot x, a_2 \cdot x)$ , we have to prove that  $(a_1 \cdot x, a_2 \cdot x)$  is a pseudoequivalence in  $\mathcal{P}$ . Let us check the transitivity: consider the following diagram

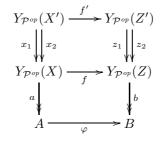

where P and P' are pullbacks, and W is a weak pullback. Since  $Y_{\mathcal{P}^{op}}(W)$  is regular projective and x is a regular epimorphism, the transitivity morphism  $t: P \to N(a)$  of  $(a_1, a_2)$  extends to a morphism  $t': Y_{\mathcal{P}^{op}}(W) \to Y_{\mathcal{P}^{op}}(X')$  such that  $t \cdot u \cdot v = x \cdot t'$ . This morphism t' is a transitivity morphism for  $(a_1 \cdot x, a_2 \cdot x)$ . The converse implication follows from Lemma 16.16, since  $Y_{\mathcal{P}^{op}}: \mathcal{P} \to [\mathcal{P}^{op}, Set]$ is left covering (see 16.12).

Note that the fact that  $(x_1, x_2)$  is a pseudoequivalence in  $\mathcal{P}$  does not mean that  $(Y_{\mathcal{P}^{op}}(x_1), Y_{\mathcal{P}^{op}}(x_2))$  is a pseudoequivalence in  $[\mathcal{P}^{op}, Set]$  because  $Y_{\mathcal{P}^{op}}$  does not preserve weak pullbacks.

**17.6 Remark.** The full subcategory of  $[\mathcal{P}^{op}, Set]$  of all objects satisfying 1. or 2. of the above lemma is denoted by  $\mathcal{P}'_{ex}$ . In the next lemma, the codomain restriction of the Yoneda embedding  $Y_{\mathcal{P}^{op}}: \mathcal{P} \to [\mathcal{P}^{op}, Set]$  to  $\mathcal{P}'_{ex}$  is again denoted by  $Y_{\mathcal{P}^{op}}$ , and  $\Gamma$  is the functor from 17.2.

**17.7 Lemma.** There exists an equivalence of categories  $\mathcal{E} : \mathcal{P}_{ex} \to \mathcal{P}'_{ex}$  such that  $\mathcal{E} \cdot \Gamma = Y_{\mathcal{P}^{op}}$ .

**Proof.** Consider the functor  $\mathcal{E}: \mathcal{P}_{ex} \to \mathcal{P}'_{ex}$  sending a morphism  $[f]: X/X' \to Z/Z'$  to the corresponding morphism  $\varphi$  between the coequalizers as in the following diagram

The functor  $\mathcal{E}$  is well-defined because a is an epimorphism and b coequalizes  $y_0$ and  $y_1$ . Moreover,  $\mathcal{E}$  is essentially surjective by definition of  $\mathcal{P}'_{ex}$ . Let us prove that  $\mathcal{E}$  is faithful: if  $\mathcal{E}[f] = \mathcal{E}[g]$ , then the pair (f, g) factorizes through the kernel pair N(b) of b, which is a regular factorization of  $(y_0, y_1)$ . Since  $Y_{\mathcal{P}^{op}}(X)$  is regular projective, this factorization extends to a morphism  $Y_{\mathcal{P}^{op}}(X) \to Y_{\mathcal{P}^{op}}(Z')$ , which shows that [f] = [g].

 $\mathcal{E} \text{ is full: given } \varphi \colon A \to B, \text{ we get } f \colon Y_{\mathcal{P}^{op}}(X) \to Y_{\mathcal{P}^{op}}(Z) \text{ by regular projectivity} \\ \text{of } Y_{\mathcal{P}^{op}}(X). \text{ Since } b \cdot f \cdot x_1 = b \cdot f \cdot x_2, \text{ we get } \overline{f} \colon Y_{\mathcal{P}^{op}}(X') \to N(b). \text{ Since } N(b) \text{ is} \\ \text{the regular factorization of } (z_1, z_2) \text{ and } Y_{\mathcal{P}^{op}}(X') \text{ is regular projective, } \overline{f} \text{ extends} \\ \text{to } f' \colon Y_{\mathcal{P}^{op}}(X') \to Y_{\mathcal{P}^{op}}(Z'). \text{ Clearly, } \mathcal{E}[f', f] = \varphi.$ 

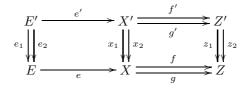

17.8 Proposition. For every category  $\mathcal{P}$  with weak finite limits, the functor

$$\Gamma \colon \mathcal{P} \to \mathcal{P}_{ex}$$

of 17.2 is a left covering functor into an exact category. Moreover, this is a regular projective cover of  $\mathcal{P}_{ex}$ .

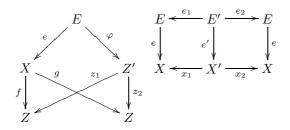

**Proof.** 1.  $\mathcal{P}_{ex}$  has finite limits. Since the construction of the other basic types of finite limits is completely analogous, we explain in details the case of equalizers, mentioning the construction for binary products and terminal object just briefly.

1a. Equalizers: Consider a parallel pair in  $\mathcal{P}_{ex}$  together with what we want to be their equalizer

This means that we need the following equations:  $x_1 \cdot e' = e \cdot e_1$  and  $x_2 \cdot e' = e \cdot e_2$ . Moreover, we request  $f \cdot e$  and  $g \cdot e$  being equivalent, that is, we need a morphism

 $\varphi \colon E \to Z'$  such that  $z_1 \cdot \varphi = f \cdot e$  and  $z_2 \cdot \varphi = g \cdot e$ . Let us take E and E' to be the following weak limits

(i) It is straightforward to check that  $(e_1, e_2)$  is a pseudoequivalence in  $\mathcal{P}$  (just use the fact that  $(x_1, x_2)$  is a pseudoequivalence).

(ii) To show that [e] equalizes [f] and [g], use the morphism  $\varphi \colon E \to Z'$ .

(iii) The morphism [e] is a monomorphism: in fact, consider two morphisms in  $\mathcal{P}_{ex}$ 

such that  $[e] \cdot [h] = [e] \cdot [k]$ . This means that there is a morphism  $\Sigma: A \to X'$ such that  $x_1 \cdot \Sigma = e \cdot h$  and  $x_2 \cdot \Sigma = e \cdot k$ . By the weak universal property of E', we have a morphism  $\Sigma': A \to E'$  such that  $e_1 \cdot \Sigma' = h$  and  $e_2 \cdot \Sigma' = k$ . This means that [h] = [k].

(iv) We prove that every morphism

$$\begin{array}{c} A' \xrightarrow{h'} X' \\ a_1 \\ \downarrow \\ A \xrightarrow{a_2} x_1 \\ \downarrow \\ A \xrightarrow{h} X \end{array}$$

in  $\mathcal{P}_{ex}$  such that  $[f] \cdot [h] = [g] \cdot [h]$  factorizes through [e]. We know that there is  $\Sigma: A \to Z'$  such that  $z_1 \cdot \Sigma = f \cdot h$  and  $z_2 \cdot \Sigma = g \cdot h$ . The weak universal property of E yields then a morphism  $k: A \to E$  such that  $e \cdot k = h$  and  $\Sigma \cdot k = \varphi$ . Now,  $x_1 \cdot h' = e \cdot k \cdot a_1$  and  $x_2 \cdot h' = e \cdot k \cdot a_2$ . The weak universal property of E' yields a morphism  $k': A' \to E'$  such that  $e_1 \cdot k' = k \cdot a_1$  and  $e_2 \cdot k' = k \cdot a_2$ . Finally, the needed factorization is  $[k', k]: A/A' \to E/E'$ .

1b. Products: Consider two objects  $x_1, x_2 \colon X' \rightrightarrows X$  and  $z_1, z_2 \colon Z' \rightrightarrows Z$  in  $\mathcal{P}_{ex}$ . Their product is given by

$$X' \stackrel{x'}{\longleftarrow} P' \stackrel{z'}{\longrightarrow} Z'$$

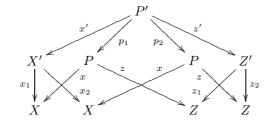

$$x_1 \bigvee_{x_2} x_2 p_1 \bigvee_{p_2} p_2 z_1 \bigvee_{z_2}$$

$$X \stackrel{x}{\longleftarrow} P \stackrel{z}{\longrightarrow} Z$$

where

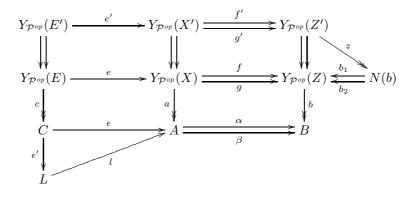

$$X \xleftarrow{x} P \xrightarrow{z} Z$$

is a weak product of X and Z in  $\mathcal{P}$ , and P' is the following weak limit

1c. Terminal object: For any object T of  $\mathcal{P}$ , the projections from a weak product  $\pi_1, \pi_2: T \times T \rightrightarrows T$  form a pseudoequivalence. If T is a weak terminal object in  $\mathcal{P}$ , then  $(\pi_0, \pi_1)$  is a terminal object in  $\mathcal{P}_{ex}$ .

2.  $\mathcal{P}_{ex}$  is closed under finite limits in  $[\mathcal{P}^{op}, Set]$ . In fact, by Lemma 17.7, we can identify  $\mathcal{P}_{ex}$  with  $\mathcal{P}'_{ex}$ . We prove that the full inclusion of  $\mathcal{P}_{ex}$  into  $[\mathcal{P}^{op}, Set]$  preserves finite limits. Because of Lemma 16.20, it is enough to prove that the inclusion is left covering. We give the argument for equalizers, since that for products and terminal object is similar (and easier). With the notations of part 1., consider the following diagram, where  $\epsilon, \alpha$  and  $\beta$  are extensions to the coequalizers, the triangle on the right is a regular factorization, and the triangle at the bottom is the factorization through the equalizer

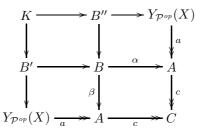

We have to prove that  $\epsilon'$  is a regular epimorphism. Using  $\varphi \colon E \to Z'$ , we check that  $\alpha \cdot a \cdot e = \beta \cdot a \cdot e$ , so that there is  $p \colon Y_{\mathcal{P}^{op}}(E) \to L$  such that  $l \cdot p = a \cdot e$ , and then  $p = \epsilon' \cdot c$ . So, it is enough to prove that p is a regular epimorphism, that is, the components  $p(P) \colon Y_{\mathcal{P}^{op}}(E)(P) \to L(P)$  are surjective. This means that, given a morphism  $u \colon Y_{\mathcal{P}^{op}}(P) \to A$  such that  $\alpha \cdot u = \beta \cdot u$ , we need a morphism  $\hat{u} \colon P \to E$  with  $l \cdot p \cdot \hat{u} = u$ . First of all, observe that, since a is a regular epimorphism and  $Y_{\mathcal{P}^{op}}(P)$  is regular projective, there is  $u' \colon P \to X$  such that  $a \cdot u' = u$ . Now,  $b \cdot f \cdot u' = b \cdot g \cdot u'$ , so that there is  $u'' \colon Y_{\mathcal{P}^{op}}(P) \to N(b)$  such that  $b_1 \cdot u'' = f \cdot u'$  and  $b_2 \cdot u'' = g \cdot u'$ . Moreover, since z is a regular epimorphism

and  $Y_{\mathcal{P}^{op}}(P)$  is regular projective, there is  $\tilde{u} \colon P \to Z'$  with  $z \cdot \tilde{u} = u''$ . Finally,  $z_1 \cdot \tilde{u} = f \cdot u'$  and  $z_2 \cdot \tilde{u} = g \cdot u'$ , so that there is  $\hat{u} \colon P \to E$  such that  $\varphi \cdot \hat{u} = \tilde{u}$  and  $e \cdot \hat{u} = u'$ . This last equation implies that  $l \cdot p \cdot \hat{u} = u$ .

3.  $\mathcal{P}_{ex}$  is closed in  $[\mathcal{P}^{op}, Set]$  under coequalizers of equivalence relations. In fact, consider an equivalence relation in  $\mathcal{P}_{ex}$ , with its coequalizer in  $[\mathcal{P}^{op}, Set]$ 

$$B \xrightarrow[\beta]{\alpha} A \xrightarrow{c} C$$

We have to prove that C lies in  $\mathcal{P}_{ex}$ . For this, consider the following diagram:

with each square except, possibly, the right-hand bottom one, a pullback. The remaining square is, then, also a pullback because  $[\mathcal{P}^{op}, Set]$  is exact,  $X \in \mathcal{P}$  and a is a regular epimorphism. Since A, B and  $Y_{\mathcal{P}^{op}}(X)$  are in  $\mathcal{P}_{ex}$ , which is closed in  $[\mathcal{P}^{op}, Set]$  under finite limits (see part 2.), also K lies in  $\mathcal{P}_{ex}$ . So, K is a regular quotient of a representable object. But K is also the kernel pair of the regular epimorphism  $c \cdot a \colon Y_{\mathcal{P}^{op}}(X) \to C$ . By Lemma 17.5, this means that C is in  $\mathcal{P}_{ex}$ .

**17.9 Corollary.** For every category  $\mathcal{P}$  with weak finite limits, the functor

$$\Gamma \colon \mathcal{P} \to \mathcal{P}_{ex}$$

of 17.2 is a free exact completion of  $\mathcal{P}$ .

In fact, this follows from 16.24 and 17.8.

17.10 Remark. Let  $\mathcal{A}$  be an algebraic category. From Chapter 7 we know that there are equivalences

$$\mathcal{A} \simeq Ind(\mathcal{A}_{fp})$$
 and  $\mathcal{A}_{fp} \simeq Rec(\mathcal{A}_{pp})$ 

where  $\mathcal{A}_{pp}$  and  $\mathcal{A}_{fp}$  are the full subcategories of  $\mathcal{A}$  of perfectly presentable objects and of finitely presentable objects, respectively, and *Rec* is the free completion under finite colimits conservative with respect to finite coproducts (see 17.11). An analogous situation holds with the exact completion. In fact, there are equivalences

$$\mathcal{A} \simeq (\mathcal{A}_{rp})_{ex} \simeq (FCSum(\mathcal{A}_{pp}))_{ex}$$
 and  $\mathcal{A}_{rp} \simeq Ic(FCSum(\mathcal{A}_{pp}))$ 

where  $\mathcal{A}_{rp}$  is the full subcategory of regular projective objects and *FCSum* is the free completion under coproducts conservative with respect to finite coproducts.

The second part of this chapter is devoted to an elementary description of the free completion under reflexive coequalizers

$$E_{Rec}: \mathcal{C} \to Rec \mathcal{C}$$

of a category C with finite coproducts, already studied in Chapter 7. Let us start by observing that 7.5 can be restated as follows.

**17.11 Proposition.** Let  $\mathcal{T}$  be an algebraic theory. The functor

$$Y_{\mathcal{T}} \colon \mathcal{T}^{op} \to (Alg \mathcal{T})_{fp}$$

is a free completion of  ${\mathcal T}$  under finite colimits, conservative with respect to finite coproducts. This means that

1.  $(Alg \mathcal{T})_{fp}$  is finitely cocomplete and  $Y_{\mathcal{T}}$  preserves finite coproducts

and

2. for every functor  $F: \mathcal{T}^{op} \to \mathcal{B}$  preserving finite coproducts, where  $\mathcal{B}$  is a finitely cocomplete category, there exists an essentially unique functor  $F^*: Alg\mathcal{T} \to \mathcal{B}$  preserving finite colimits with F naturally isomorphic to  $F^* \cdot Y_{\mathcal{T}}$ .

We pass now to the elementary description of  $Rec\mathcal{C}$ .

**17.12 Definition.** Given a category C with finite coproducts, we define the category RecC as follows:

- 1. Objects of  $Rec\mathcal{C}$  are reflexive pairs  $x_1, x_2 \colon X_1 \rightrightarrows X_0$  in  $\mathcal{C}$  (that is, parallel pairs for which there exists  $d \colon X_0 \to X_1$  such that  $x_1 \cdot d = \operatorname{id}_{X_0} = x_2 \cdot d$ , see 3.12).
- 2. Consider the following diagram in  $\mathcal{C}$

$$V \xrightarrow{f} Z_{0} Z_{0}$$

with  $z_1, z_2$  a reflexive pair. We write

 $h\colon f\mapsto g$ 

if there exists a morphism  $h: V \to Z_1$  such that  $z_1 \cdot h = f$  and  $z_2 \cdot h = g$ . This is a reflexive relation in the hom-set  $\mathcal{C}(V, Z_0)$ . We write  $f \sim g$  if f and g are in the equivalence relation generated by this reflexive relation.

February 1, 2010

180

3. A premorphism in Rec C from  $(x_1, x_2)$  to  $(z_1, z_2)$  is a morphism f in C as in the diagram

such that  $f \cdot x_1 \sim f \cdot x_2$ .

- 4. A morphism in RecC from  $(x_1, x_2)$  to  $(z_1, z_2)$  is an equivalence class [f] of premorphisms with respect to the equivalence  $\sim$  of 2.
- 5. Composition and identities in Rec C are the obvious ones.
- 6. The functor  $E_{Rec}: \mathcal{C} \to Rec \mathcal{C}$  is defined by

$$P(X \xrightarrow{f} Z) = X \xrightarrow{id} [f] X \xrightarrow{Z} Z$$

#### 17.13 Remark.

1. Consider

as in 17.12. Explicitly,  $f\sim g$  means that there exists a zig-zag

- 2. Using the explicit description of  $f \sim g$ , it is straightforward to prove that  $Rec\mathcal{C}$  is a category and  $P: \mathcal{C} \to Rec\mathcal{C}$  is a full and faitful functor.
- 3. The above description of  $P: \mathcal{C} \to Rec\mathcal{C}$  does not depend on the existence of finite coproducts in  $\mathcal{C}$

**17.14 Lemma.** Let C be a category with finite coproducts. The category RecC of 17.12 has finite colimits and  $E_{Rec}: C \to RecC$  preserves finite coproducts.

**Proof.** (1) Finite coproducts in Rec C are computed componentwise, i.e., if  $x_1, x_2: X_1 \rightrightarrows X_0$  and  $z_1, z_2: Z_1 \rightrightarrows Z_0$  are objects of Rec C, their coproduct is

$$X_{1} \qquad X_{1} \coprod Z_{1} \qquad Z_{1}$$

$$x_{1} \coprod x_{2} \qquad x_{1} \coprod z_{1} \coprod x_{2} \coprod z_{2} \qquad z_{1} \coprod z_{2}$$

$$X_{0} \xrightarrow{[i_{X_{0}}]} X_{0} \coprod Z_{0} \xleftarrow{[i_{Z_{0}}]} Z_{0}$$

(2) Reflexive coequalizers in Rec C are depicted in the following diagram

$$X_{1} \qquad Z_{1} \qquad X_{0} \coprod Z_{1}$$

$$x_{1} \oiint x_{2} \qquad z_{1} \oiint z_{2} \qquad \langle f, z_{1} \rangle \oiint \langle g, z_{2} \rangle$$

$$X_{0} \xrightarrow{[f]} \qquad Z_{0} \xrightarrow{[id]} Z_{0}$$

17.15 Lemma. Consider the diagram

$$V \xrightarrow{f} Z_{0} Z_{0}$$

as in 17.12. If a morphism  $w: Z_0 \to W$  is such that  $w \cdot z_1 = w \cdot z_2$  and  $f \sim g$ , then  $w \cdot f = w \cdot g$ .

**Proof.** Clearly if  $h: f \mapsto g$ , then  $w \cdot f = w \cdot g$ . The claim now follows from the fact that to be coequalized by w is an equivalence relation in  $\mathcal{C}(V, Z_0)$ .

**17.16 Remark.** For every reflexive pair  $x_1, x_2 \colon X_1 \rightrightarrows X_0$  in  $\mathcal{C}$ , the diagram

$$E_{Rec} X_1 \xrightarrow{E_{Rec} x_1} E_{Rec} X_0 \xrightarrow{[\mathrm{id}_{X_0}]} (X_1 \xrightarrow{x_1} X_0)$$

is a reflexive coequalizer in  $Rec\mathcal{C}$ . Therefore, if two functors  $F, G: Rec\mathcal{C} \to \mathcal{B}$ preserve reflexive coequalizers and  $F \cdot E_{Rec} \simeq G \cdot E_{Rec}$ , then  $F \simeq G$ .

**17.17 Proposition.** Let C be a category with finite coproducts. The functor

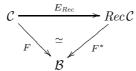

$$E_{Rec}: \mathcal{C} \to Rec \mathcal{C}$$

of 17.12 is a free completion of C under finite colimits, conservative with respect to finite coproducts. This means that

1. Rec C has finite colimits and  $E_{Rec}$  preserves finite coproducts

#### and

2. for every functor  $F: \mathcal{C} \to \mathcal{B}$  preserving finite coproducts, where  $\mathcal{B}$  is a finitely cocomplete category, there exists an essentially unique functor  $F^*: \operatorname{Rec} \mathcal{C} \to \mathcal{B}$  preserving finite colimits with F naturally isomorphic to  $F^* \cdot E_{\operatorname{Rec}}$ .

**Proof.** Given  $F: \mathcal{C} \to \mathcal{B}$  as above, we define  $F^*: Rec\mathcal{C} \to \mathcal{B}$  on objects by the following coequalizer in  $\mathcal{B}$ :

$$FX_1 \xrightarrow{Fx_1} FX_0 \longrightarrow F^*(x_1, x_2)$$

Lemma 17.15 makes it clear how to define  $F^*$  on morphisms. The argument for the essential uniqueness of  $F^*$  is stated in 17.16. The rest of the proof is straightforward.

The previous universal property allows us to give a different prove of the equation  $Sind\mathcal{C} \simeq Ind(Rec\mathcal{C})$  already established in 7.4.

**17.18 Corollary.** Let C be a small category with finite coproducts. There exists an equivalence of categories

$$Ind(Rec C) \simeq Sind C$$

**Proof.** Let  $\mathcal{B}$  be a cocomplete category. By 4.18, the functors  $Ind(RecC) \rightarrow \mathcal{B}$  preserving colimits correspond to the functors  $RecC \rightarrow \mathcal{B}$  preserving finite colimits and then, by 17.17, to the functors  $\mathcal{C} \rightarrow \mathcal{B}$  preserving finite coproducts. On the other hand, the functors  $\mathcal{C} \rightarrow \mathcal{B}$  preserving finite coproducts correspond, by 15.13, to the functors  $SindC \rightarrow \mathcal{B}$  preserving colimits. Since both Ind(RecC) and SindC are cocomplete (4.16 and 4.5), we can conclude that Ind(RecC) and SindC are equivalent categories.

## Historical Remarks for Chapter 17

The reflexive coequalizer completion of a category with finite coproducts is due to A. M. Pitts (unpublished notes [80]). It appeared in press in [32]. The connection between the exact completion and the reflexive coequalizer completion was established by M. C. Pedicchio and J. Rosický in [76], see also [85] for the connection with homological functors.

## Chapter 18

# Finitary localizations of algebraic categories

We know from Chapter 6 that algebraic categories are precisely the cocomplete categories having a strong generator formed by perfectly presentable objects. We prove now that among exact categories the algebraic ones are precisely the cocomplete categories having a strong generator formed by finitely presentable regular projectives. As a consequence we fully characterize all finitary localizations of algebraic categories as the exact, locally finitely presentable categories.

**18.1 Theorem.** Let  $\mathcal{E}$  be an exact category with sifted colimits,  $\mathcal{A}$  a category with finite limits and sifted colimits, and  $F: \mathcal{E} \to \mathcal{A}$  a functor preserving finite limits and filtered colimits. Then F preserves reflexive coequalizers if and only if it preserves regular epimorphisms.

**Proof.** Necessity is evident, because every regular epimorphism is a reflexive coequalizer of its kernel pair. For sufficiency, let F preserve finite limits, filtered colimits and regular epimorphisms.

1. Since every equivalence relation in  $\mathcal{E}$  is a kernel pair of its coequalizer and since every regular epimorphism is a coequalizer of its kernel pair, F preserves coequalizers of equivalence relations. Since every pseudoequivalence in  $\mathcal{E}$  can be decomposed as a regular epimorphism followed by an equivalence relation (cf. 16.16), F preserves coequalizers of pseudoequivalences.

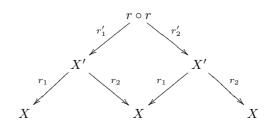

2. Consider a reflexive and symmetric pair  $r = (r_1, r_2 \colon X' \rightrightarrows X)$  of morphisms in  $\mathcal{E}$ . We construct a pseudoequivalence  $\overline{r}$  containing r (the *transitive hull* of r) as a (filtered) colimit of the chain of compositions

 $r \circ r \circ \ldots \circ r$  *n*-times

(the composition  $r \circ r$  is depicted in the following diagram, where the square is

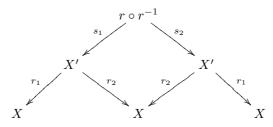

## CHAPTER 18. FINITARY LOCALIZATIONS OF ALGEBRAIC CATEGORIES

a pullback)

Since F preserves filtered colimits and finite limits, we have  $\overline{Fr} = F\overline{r}$ . The pseudoequivalence  $\overline{r}$  has a coequalizer, which is preserved by F. But a coequalizer of  $\overline{r}$  is also a coequalizer of r, and so F preserves coequalizers of reflexive and symmetric pairs of morphisms.

3. If  $r = (r_1, r_2)$  is just a reflexive pair, then a reflexive and symmetric pair containing r is given by  $r \circ r^{-1}$ , that is

Once again, a coequalizer of  $r \circ r^{-1}$  is also a coequalizer of r, so that F preserves reflexive coequalizers.

**18.2 Corollary.** Let  $\mathcal{E}$  be a cocomplete exact category,  $\mathcal{A}$  a category with finite limits and sifted colimits and  $F: \mathcal{E} \to \mathcal{A}$  a functor preserving finite limits. Then F preserves sifted colimits if and only if it preserves filtered colimits and regular epimorphisms.

In fact, this follows from 7.7 and 18.1. We can now generalize 5.16.

**18.3 Corollary.** In a cocomplete exact category, perfectly presentable objects are precisely finitely presentable regular projectives.

**Proof.** One implication is established in 5.4. For the converse implication, apply 18.2 to the hom-functor hom(G, -) of a finitely presentable regular projective object G.

**18.4 Corollary.** A category is algebraic if and only if it is cocomplete, exact and has a strong generator consisting of finitely presentable regular projectives.

**Proof.** Necessity follows from 3.18 and 6.9. Sufficiency follows from 18.3 and 6.9.  $\hfill \Box$ 

In the previous corollary, the assumption of cocompleteness can be reduced to asking for the existence of coequalizers of kernel pairs, which is part of the

# CHAPTER 18. FINITARY LOCALIZATIONS OF ALGEBRAIC CATEGORIES

exactness of the category, and the existence of coproducts of objects from the generator. In fact, we have the following result (recall that a category is *wellpowered* if, for a fixed object A, the subobjects of A constitute a set (not a proper class):

**18.5 Lemma.** Let  $\mathcal{A}$  be a well-powered exact category with a regular projective cover  $\mathcal{P} \to \mathcal{A}$ . If  $\mathcal{P}$  has coproducts, then  $\mathcal{A}$  is cocomplete.

**Proof.** 1. The functor  $\mathcal{P} \to \mathcal{A}$  preserves coproducts. Indeed, consider a coproduct

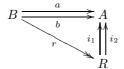

$$s_i \colon P_i \to \coprod_I P_i$$

in  $\mathcal{P}$ , and a family of morphisms  $\langle x_i \colon P_i \to X \rangle_I$  in  $\mathcal{A}$ . Let  $q \colon Q \to X$  be a regular epimorphism with  $Q \in \mathcal{P}$ . For each  $i \in I$ , consider a morphism  $y_i \colon P_i \to Q$  such that  $q \cdot y_i = x_i$ . Since Q is in  $\mathcal{P}$ , there is  $y \colon \coprod_I P_i \to Q$  such that  $y \cdot s_i = y_i$ , and then  $q \cdot y \cdot s_i = x_i$ , for all  $i \in I$ .

As far as the uniqueness of the factorization is concerned, consider a pair of morphisms  $f, g: \coprod_I P_i \rightrightarrows X$  such that  $s_i \cdot f = s_i \cdot g$  for all *i*. Consider also  $f', g': \coprod_I P_i \rightrightarrows Q$  such that  $q \cdot f' = f$  and  $q \cdot g' = g$ . Since  $q \cdot f' \cdot s_i = q \cdot g' \cdot s_i$ , there is  $t_i: P_i \rightarrow N(q)$  such that  $q_1 \cdot t_i = f' \cdot s_i$  and  $q_2 \cdot t_i = g' \cdot s_i$ , where  $q_1, q_2 \cdot N(q) \rightrightarrows Q$  is a kernel pair of q. From the first part of the proof, we obtain a morphism  $t: \coprod_I P_i \rightarrow N(q)$  such that  $t \cdot s_i = t_i$  for all *i*. Moreover,  $q_1 \cdot t \cdot s_i = f' \cdot s_i$  for all *i*, so that  $q_1 \cdot t = f'$  because Q is in  $\mathcal{P}$ . Analogously,  $q_2 \cdot t = g'$ . Finally,  $f = q \cdot f' = q \cdot q_1 \cdot t = q \cdot q_2 \cdot t = q \cdot g' = g$ .

2. Recall that  $Sub_{\mathcal{A}}(A)$  is the ordered class of subobjects of A. For every category  $\mathcal{A}$ , we denote by  $\theta(\mathcal{A})$  its "ordered reflection", i.e., the ordered class obtained from the preorder on the objects of  $\mathcal{A}$  given by  $A \leq B$  iff  $\mathcal{A}(A, B)$  is nonempty. We are going to prove that for any object A of  $\mathcal{A}$ ,  $Sub_{\mathcal{A}}(A)$  and  $\theta(\mathcal{P}/A)$  are isomorphic ordered classes. In fact, given a monomorphism  $m: X \to A$ , we consider a  $\mathcal{P}$ -cover  $q: Q \to X$  and we get an element in  $\theta(\mathcal{P}/A)$  from the composition  $m \cdot q$ . Conversely, given an object  $f: Q \to A$  in  $\mathcal{P}/A$ , the monomorphic part of its regular factorisation gives an element in  $Sub_{\mathcal{A}}(A)$ .

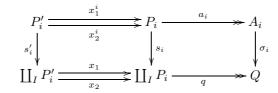

3.  $\mathcal{A}$  has coequalizers. Consider a parallel pair (a, b) in  $\mathcal{A}$  and its regular factorization

Consider now the equivalence relation  $a_1, a_2: A' \Rightarrow A$  generated by  $(i_1, i_2)$ , that is the intersection of all the equivalence relations on A containing  $(i_1, i_2)$ . Such an intersection exists: by part 2.,  $Sub_{\mathcal{A}}(A)$  is isomorphic to  $\theta(\mathcal{P}/A)$ , which is cocomplete because  $\mathcal{P}$  has coproducts. Since, by assumption,  $\mathcal{A}$  is well-powered,  $Sub_{\mathcal{A}}(A)$  is a set, and a cocomplete ordered set is also complete. Since  $\mathcal{A}$  is exact,  $(a_1, a_2)$  has a coequalizer, which is also a coequalizer of  $(i_1, i_2)$  and then of (a, b). 4.  $\mathcal{A}$  has coproducts. Consider a family of objects  $(A_i)_I$  in  $\mathcal{A}$ . Each of them can

## CHAPTER 18. FINITARY LOCALIZATIONS OF ALGEBRAIC CATEGORIES

be seen as a coequalizer of a pseudoequivalence in  $\mathcal{P}$  as in the following diagram, where the first and the second columns are coproducts in  $\mathcal{P}$  (and then in  $\mathcal{A}$ , see 1.),  $x_0$  and  $x_1$  are the extensions to the coproducts, the bottom row is a coequalizer (which exists by Part 3.), and  $\sigma_i$  is the extension to the coequalizer.

Since coproducts commute with coequalizers, the third column is a coproduct of the family  $(A_i)_I$ .

**18.6 Corollary.** A category is algebraic if and only if it is exact and has a strong generator  $\mathcal{G}$  consisting of finitely presentable regular projectives such that coproducts of objects of  $\mathcal{G}$  exist.

**Proof.** Let  $\mathcal{A}$  be an exact category and  $\mathcal{G}$  a strong generator consisting of regular projectives. Since a coproduct of regular projectives is regular projective, the full subcategory  $\mathcal{P}$  consisting of coproducts of objects from  $\mathcal{G}$  is a regular projective cover of  $\mathcal{A}$ . Following 18.5, it remains to prove that  $\mathcal{A}$  is well-powered. Consider an object A and the map

$$\mathcal{F}\colon \Omega(\mathcal{G}\downarrow A)\to Sub_{\mathcal{A}}(A)$$

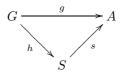

assigning to a subset  $\mathcal{M}$  of  $\mathcal{G} \downarrow A$  the subobject of A represented by the monomorphism  $s_{\mathcal{M}} \colon S_{\mathcal{M}} \to A$ , where

$$e_{\mathcal{M}} \colon \coprod_{(G,g)\in\mathcal{M}} G \to A$$

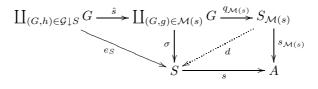

is the canonical morphism whose (G, g)-component is g, and

$$\coprod_{(G,g)\in\mathcal{M}}G\xrightarrow{q_{\mathcal{M}}}S_{\mathcal{M}}\xrightarrow{s_{\mathcal{M}}}A$$

is the regular factorization of  $e_{\mathcal{M}}$ . We are to prove that  $\mathcal{F}$  is surjective, so that  $Sub_{\mathcal{A}}(A)$  is a set. For this, consider a monomorphism  $m: S \to A$  and let  $\mathcal{M}(s)$  be the set of those  $(G,g) \in \mathcal{G} \downarrow A$  such that g factorizes through s:

We get the commutative diagram

February 1, 2010

188

# CHAPTER 18. FINITARY LOCALIZATIONS OF ALGEBRAIC CATEGORIES

where the (G, h)-components of  $e_S$  and  $\hat{s}$  are h and g, respectively, and the (G, g)-component of  $\sigma$  is h. By diagonal fill-in there exists  $d: S_{\mathcal{M}(s)} \to S$  such that  $d \cdot q_{\mathcal{M}(s)} = \sigma$  and  $s \cdot d = s_{\mathcal{M}(s)}$ . Such a d is an isomorphism: it is a monomorphism because  $s_{\mathcal{M}(s)}$  is, and an extremal epimorphism because  $e_S$  is. Thus,  $\mathcal{F}(\mathcal{M}(s)) = s$  and the proof is complete.

From Propositions 3.18 and 6.22, we know that an algebraic category is exact and locally finitely presentable. The converse is not true because of the lack of projectivity of the generator. In the remaining part of this chapter we want to state in a precise way the relationship between algebraic categories and exact, locally finitely presentable categories.

**18.7 Definition.** Given a category  $\mathcal{B}$ , by a *localization* of  $\mathcal{B}$  is meant a full reflective subcategory  $\mathcal{A}$  whose reflector preserves finite limits. And  $\mathcal{A}$  is called a *finitary localization* if, moreover, it is closed in  $\mathcal{B}$  under filtered colimits.

**18.8 Remark.** More loosely, we speak about localizations of  $\mathcal{B}$  as categories equivalent to full subcategories having the above property. We use the notation

$$\mathcal{A} \xrightarrow[I]{R} \mathcal{B}$$

that is, R is left adjoint to I and I is full and faithful.

Let us start with a general lemma.

18.9 Lemma. Consider a full reflection

$$\mathcal{A} \xrightarrow[I]{R} \mathcal{B}$$

- 1. If I preserves filtered colimits and an object  $P \in \mathcal{B}$  is finitely presentable, then R(P) is finitely presentable;
- 2. If the reflection is a localization and  $\mathcal{B}$  is exact, then  $\mathcal{A}$  is exact.

**Proof.** 1. Same argument as in the proof of 6.16.1.

2. Let  $r_1, r_2: A' \Rightarrow A$  be an equivalence relation in  $\mathcal{A}$ . Its image in  $\mathcal{B}$  is an equivalence relation, so that it has a coequalizer Q and it is the kernel pair of its coequalizer (because  $\mathcal{B}$  is exact)

$$IA' \xrightarrow{Ir_1} IA \xrightarrow{q} Q$$

If we apply the functor R to this diagram, we obtain a coequalizer (because R is a left adjoint) and a kernel pair (because R preserves finite limits)

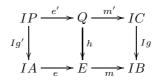

$$RIA' \simeq A' \xrightarrow[r_2]{r_1} A \simeq RIA \xrightarrow{Rq} RQ$$

## CHAPTER 18. FINITARY LOCALIZATIONS OF ALGEBRAIC CATEGORIES

and this means that  $(r_1, r_2)$  is effective. It remains to prove that regular epimorphisms are stable under pullbacks. For this, consider a pullback

in  $\mathcal{A}$ , with f a regular epimorphism. Form its image in  $\mathcal{B}$ , computed as a two-step pullback of Ig along the regular factorization  $m \cdot e$  of If

so that e' is a regular epimorphism. If we apply the functor R to the second diagram, we come back to the original pullback, computed now as a two-step pullback (because R preserves finite limits)

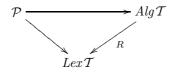

Now observe that Rm is a monomorphism (because R preserves finite limits) and also a regular epimorphism (because f is a regular epimorphism, and  $Rm \cdot Re = f$ ), so that it is an isomorphism. It follows that Rm' is an isomorphism. Moreover, Re' is a regular epimorphism (because R, being a left adjoint, preserves regular epimorphisms). Finally, f' is a regular epimorphism because  $f' = Rm' \cdot Re'$ .

**18.10 Theorem.** Finitary localizations of algebraic categories are precisely the exact, locally finitely presentable categories.

**Proof.** Since an algebraic category is exact and locally finitely presentable, necessity follows from 6.16.1 and 18.9. For the sufficiency, let  $\mathcal{A}$  be an exact and locally finitely presentable category. Following 6.26,  $\mathcal{A}$  is equivalent to  $Lex\mathcal{T}$ , where  $\mathcal{T} \simeq \mathcal{A}_{fp}^{op}$ , and  $Lex\mathcal{T}$  is a full reflective subcategory of  $Alg\mathcal{T}$  closed under filtered colimits (see 6.29). Consider the full subcategory  $\mathcal{P}$  of  $Alg\mathcal{T}$  consisting of regular projective objects. Such an object P is a retract of a coproduct of representable algebras (5.14.2). Since every coproduct is a filtered colimit of its finite subcoproducts, and a finite coproduct of representable algebras. Following 4.3, we have that  $\mathcal{P}$  is contained in  $Lex\mathcal{T}$ . Moreover,  $\mathcal{P}$  is a regular

# CHAPTER 18. FINITARY LOCALIZATIONS OF ALGEBRAIC CATEGORIES

projective cover of  $Alg \mathcal{T}$  (5.15). Since, by 16.27, the full inclusion of  $\mathcal{P}$  into  $Alg \mathcal{T}$  is a free exact completion of  $\mathcal{P}$  and, by assumption,  $Lex \mathcal{T}$  is exact, it remains just to prove that the inclusion  $\mathcal{P} \to Lex \mathcal{T}$  is left covering. Once this is done, we can apply 16.26 to the following situation

where R is the reflector, and we conclude that R is an exact functor. But the inclusion  $\mathcal{P} \to Alg \mathcal{T} \simeq \mathcal{P}_{ex}$  is left covering, and  $Lex\mathcal{T}$  is closed in  $Alg\mathcal{T}$  under limits, so that also the inclusion  $\mathcal{P} \to Lex\mathcal{T}$  is left covering.

18.11 Remark. To finish this chapter, we observe that Corollary 18.2 can be used to prove the characterization of varieties established in 10.24 without using Birkhoff's Variety Theorem 10.22. We sketch the argument. Let  $\mathcal{T}$  be an algebraic theory and

$$I: \mathcal{A} \to Alg \mathcal{T} , \ R \dashv I$$

a regular epireflective subcategory closed under regular quotients and directed unions. From the closedness under regular quotients it immediately follows that I preserves regular epimorphisms and that in  $\mathcal{A}$  equivalence relations are effective, so that  $\mathcal{A}$  is exact. To prove that I preserves filtered colimit, consider a functor  $F: \mathcal{D} \to \mathcal{A}$  with  $\mathcal{D}$  filtered and let  $\langle \sigma_d \colon Fd \to B \rangle_{d \in \mathcal{D}}$  be its colimit cocone in  $Alg \mathcal{T}$ . Let

$$Fd \xrightarrow{e_d} Gd \xrightarrow{m_d} B$$

be the regular factorization of  $\sigma_d$ . For any morphism  $f: d \to d'$  in  $\mathcal{D}$  there exists a unique  $Gf: Gd \to Gd'$  such that  $m_{d'} \cdot Gf = m_d$  (use diagonal fill-in, cf. 0.16). This defines a new functor  $G: \mathcal{D} \to \mathcal{A}$  (indeed  $Gd \in \mathcal{A}$  because it is a regular quotient of  $Fd \in \mathcal{A}$ ) and B is the directed union of the Gd's, so that  $B \in \mathcal{A}$ . Following 18.2 I preserves sifted colimits and then by 6.18  $\mathcal{A}$  is algebraic. Moreover, an algebraic theory  $\mathcal{T}_{\mathcal{A}}$  of  $\mathcal{A}$  can be described as follows (cf. 6.16):

$$\mathcal{T}_{\mathcal{A}}^{op} = \{ R(\mathcal{T}(X, -)) \mid X \in \mathcal{T} \}$$

The functor

$$\mathcal{T} \to \mathcal{T}_{\mathcal{A}}, \ X \mapsto R(\mathcal{T}(X, -))$$

preserves finite products (by 1.13) and is surjective on objects. It remains to prove that it is also full: let  $\eta$  be the unit of the adjunction  $R \dashv I$  and consider  $f: R(\mathcal{T}(X, -)) \to R(\mathcal{T}(Z, -))$ . Since  $\eta_{\mathcal{T}(Z, -)}$  is a regular epimorphism and  $\mathcal{T}(X, -)$  is regular projective, there exists  $g: \mathcal{T}(X, -) \to \mathcal{T}(Z, -)$  such that  $f \cdot \eta_{\mathcal{T}(X, -)} = \eta_{\mathcal{T}(Z, -)} \cdot g$ . Since  $\eta$  is natural and  $\eta_{\mathcal{T}(X, -)}$  is an epimorphism, it follows that Rg = f. By 10.13  $\mathcal{T}_{\mathcal{A}}$  is a quotient of  $\mathcal{T}$ . Finally

$$\mathcal{A} \simeq Alg \mathcal{T}_{\mathcal{A}} \simeq Alg \left( \mathcal{T} / \sim \right)$$

so that  $\mathcal{A}$  is a variety of  $\mathcal{T}$ -algebras.

## Historical Remarks for Chapter 18

The first systematic study of localizations is due to P. Gabriel [44] who also together with N. Popesco characterized Grothendieck categories, see [81]. This is an ancestor of Theorem 18.10.

Arbitrary (i.e., non necessarily finitary) localizations of one-sorted algebraic categories and, more generally, of monadic categories over *Set* are characterized in [92] and in [93]. Essential localizations are studied in [10], which generalizes the original result for module categories due to J. E. Roos [86].

One of the results of Lawvere's thesis [60] is a characterization of one-sorted algebraic categories, compare with Corollary 18.6. The only difference is that in Lawvere's original result the generator is required to be abstractly finite, a notion that without the other conditions of the characterization theorem is weaker than finitely presentable.

# Postscript

In this postscript we intend to explain somewhat the position our book has in the literature on algebra and category theory. And we want to mention some of the important topics that we decided not to deal with in our book.

One-sorted algebraic theories provide a very convenient formalization, based on the concept of finite product, of the classical concept of "the collection of all algebraic operations" present in a given kind of algebras, e.g., in groups or boolean algebras. These theories lead to concrete categories  $\mathcal{A}$  of algebras, i.e., to categories equipped with a faithful functor  $U: \mathcal{A} \to Set$ . They can be also used to find an algebraic information present in a given concrete category  $\mathcal{A}$ : we can form the algebraic theory whose *n*-ary operations are precisely the natural transformations  $U^n \to U$ . In the case of groups (and in any one-sorted algebraic category) these "implicit" operations are explicit, i.e., they correspond to operations of the theory of groups. But, on finite algebras (e.g., finite semigroups) there exist implicit operations which are not explicit and they are important in the theory of automata (see [14]). The passages from one-sorted algebraic theories to one-sorted algebraic categories and back form a duality which is a biequivalence in general, and an equivalence if we restrict one-sorted algebraic categories to uniquely transportable ones. The latter limitation is caused by a small disadvantage of the formalization based on finite products: a finite product of sets is only isomorphic to the cartesian product and thus a finite-product preserving functor from a one-sorted algebraic theory to the category of sets is, in general, only isomorphic to a "real" algebra.

General algebraic theories formalize many-sorted algebras. Moreover, the sorting is also variable: whereas classical theories such as groups, boolean algebras etc. are one-sorted, we have seen important many-sorted theories for the same algebraic categories. For example the so-called canonical theory of boolean algebras has infinitely many sorts. This canonical theory, which is a foundation of the duality between algebraic categories, is obtained from any algebraic theory by splitting of idempotents. Its objects do not correspond to finitely generated free algebras but to finitely presentable regular projective algebras. This does not play any role for groups, because regular projective groups are free, but it is crucial for R-modules. Thus the approach of the general algebraic theories goes beyond the traditional algebraic boundaries, e.g, it touches homological algebra where (regular) projective resolutions are more important than the free ones. The case of chain complexes of R-modules is even more illuminating because finitely presentable regular projective algebras coincide with perfect chain complexes. Forgetting sorts means that we have to consider algebraic categories just as abstract categories, and not equipped with a faithful functor to the category of (many)-sorted sets. But there is a way of finding an algebraic information present in a given abstract category which takes the dual of the full subcategory of finitely presentable regular projectives. This leads to the duality between canonical algebraic theories and algebraic categories.

Algebraic theories immediately lead to sifted colimits, i.e., colimits which commute with finite products in sets. In the practise of general algebra these colimits are mostly reduced to filtered colimits and quotients of congruences, and it has taken quite a long time to understand the importance of reflexive coequalizers. Algebraic categories are the free completions of small categories under sifted colimits, which puts them in between locally finitely presentable categories and presheaf categories. The fact that algebras are set-valued functors links general algebra with fields like algebraic geometry, where set-valued functors play an important role as sheaves (especially under the influence of Grothendieck [15]). Grothendieck toposes, which are the categories of sheaves, can be characterized as the localizations of presheaf categories. In the additive case, one precisely gets Grothendieck categories which are the localizations of categories of modules. Analogously, we have presented a characterization of finitary localizations of algebraic categories. Both the characterization of algebraic categories and of their localizations are the combination of exactness properties and a smallness condition (the existence of a suitable generator). Categories satisfying all exactness properties of algebraic categories but no smallness condition form the "equational hull" of varieties where "operations and equations" are not set-like but category-like. For instance, taking a reflexive coequalizer is an operation whose arity is a category, in fact, the reflexive pair. In contrast, the classical construction of forming quotients modulo all congruences cannot be considered as such an operation (which illustrates the importance of reflexive coequalizers in general algebra). The equational hull of varieties was found in [6], which solved the open problem from [61].

One-sorted algebraic theories are closely linked to monads over sets, in fact, they precisely correspond to finitary monads. In the same way, S-sorted algebraic theories correspond to finitary monads over S-sorted sets. J. Power [82] extended this correspondence to certain symmetric monoidal closed categories  $\mathcal{V}$  by introducing enriched Lawvere theories and showing that they correspond to finitary  $\mathcal{V}$ -monads on  $\mathcal{V}$ . His approach covers some "non-algebraic" cases as well, for example torsion-free abelian groups which are presented by a finitary

## . POSTSCRIPT

monad on abelian groups. This is caused by the fact that on abelian groups, contrary to sets (and S-sorted sets), there exist finitary monads which do not preserve sifted colimits. Power's approach can be modified to  $\mathcal{V}$ -monads preserving sifted colimits (see [57]) on symmetric monoidal closed categories somewhat more restricted than above. But to deal with monads on symmetric monoidal categories in general, one has to move from Lawvere theories to operads, i.e., from finite products to the tensor product (see [69] and [27]). This leads to "general algebra over  $\mathcal{V}$ " (see [66] or [94]). Each operad induces a monad on  $\mathcal{V}$  and these operadic monads preserve sifted colimits (see [83]).

Given a one-sorted algebraic theory, one can consider its algebras in any category  $\mathcal{K}$  having finite products. For instance, for the theory of groups, the algebras in the category of topological spaces are the topological groups, or its algebras in the category of smooth manifolds are the Lie groups. But our characterization of algebraic categories strongly depends on the exactness properties of sets and is not applicable in general. Surprisingly, this can be transformed to the homotopy setting where it reflects the exactness properties of the homotopy category of simplicial sets (which is equivalent to the classical homotopy category of topological spaces). One considers homotopy algebras of  $\mathcal{T}$ : they are functors  $A: \mathcal{T} \to SSet$  preserving finite products up to homotopy, which means that the canonical maps

$$A(t_1 \times \cdots \times t_n) \to A(t_1) \times \cdots \times A(t_n)$$

are not isomorphisms but weak equivalences. An analogy of sifted colimits emerges, but reflexive coequalizers are replaced by the homotopy colimits of simplicial objects (a reflexive pair is the 2-truncation of a simplicial object). The resulting characterization of homotopy varieties can be found in [84]; independently it was presented by J. Lurie [67] using the language of quasi-categories of A. Joyal [55].

. POSTSCRIPT

# Appendix A

# Monads

An important aspect of algebraic categories which has not yet been treated in this book are monads. The aim of this appendix is to give a short introduction to monads on a category  $\mathcal{K}$ , and then to explain how finitary monads for  $\mathcal{K} = Set$  precisely yield one-sorted algebraic theories, and for  $\mathcal{K} = Set^S$  the S-sorted ones.

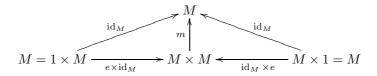

The word "monad" stems from monoid: recall that a monoid in a category  $\mathcal{K}$  is an object M together with a morphism  $m \colon M \times M \to M$  which

1. is associative, that is, the square

$$\begin{array}{c|c} M \times M \times M & \xrightarrow{m \times \mathrm{id}_M} & M \times M \\ \downarrow^{\mathrm{id}_M \times m} & & \downarrow^m \\ M \times M & \xrightarrow{m} & M \end{array}$$

commutes, and

2. has a unit, that is a morphism  $e: 1 \to M$  such that the triangles

commute.

## A.1 Definition.

- 1. A monad  $\mathbb M$  on a category  $\mathcal K$  consists of an endofunctor M on  $\mathcal K$  and natural transformations
  - (a)  $\mu: MM \to M$  (monad multiplication) and

(b)  $\eta: \operatorname{Id}_{\mathcal{K}} \to M \pmod{\operatorname{unit}}$ 

such that the diagrams

$$\begin{array}{cccc} MMM & \stackrel{M\mu}{\longrightarrow} MM & [A.1] \\ \mu M & & & & & \\ MM & \stackrel{\mu}{\longrightarrow} M & & \end{array}$$

and

$$M \xrightarrow{M} M \xrightarrow{M} M$$

$$M \xrightarrow{M} M \xrightarrow{M} M$$

$$M \xrightarrow{M} M \xrightarrow{M} M$$

$$M \xrightarrow{M} M$$

$$M \xrightarrow{M} M$$

commute.

2. The monad is called *finitary* if M is a finitary functor.

## A.2 Example.

1. The functor  $M: Set \to Set$  given by

$$MX = X + 1$$

carries an obvious structure of a monad: the unit is the coproduct injection  $\eta_X \colon X \to X + 1$  and the multiplication  $\mu_X \colon X + 1 + 1 \to X + 1$  merges the two copies of 1 to one.

2. The word monad on Set assigns to every set X the set

$$MX = X^*$$

of all words on it, that is, the (underlying set of the) free monoid on X. This yields an endofunctor on *Set* together with natural transformations  $\eta_X \colon X \to X^*$ , the formation of one-letter words, and  $\mu_X \colon (X^*)^* \to X^*$  given by concatenation of words.

3. Recall that for every finitary endofunctor H of Set free H-algebras exist, giving a left adjoint  $F_H: Set \to H$ -Alg (see 12.7). The corresponding monad  $H^*$  on Set is called the free monad on H. For example, if H is the polynomial functor of a signature  $\Sigma$ , the free monad is the monad of  $\Sigma$ -terms.

In the notation of 12.6 we have two natural transformations

$$\eta \colon \mathrm{Id} \to U_H F_H = H^*$$

 $\varphi \colon HH^* \to H^*$ 

and

yielding a natural transformation

$$\psi = \varphi \cdot H\eta \colon H \to H^* \,.$$

We will see in A.28 that it has the universal property explaining the name free monad.

A.3 Example. The basic example of a monad is that induced by any adjoint situation

$$\mathcal{A} \xrightarrow{F} \mathcal{K} \quad \text{where } F \dashv U.$$

Let  $\eta: \operatorname{Id}_{\mathcal{K}} \to UF$  and  $\varepsilon: FU \to \operatorname{Id}_{\mathcal{A}}$  denote the unit and counit of the adjunction. Recall the equalities

$$U = U\varepsilon \cdot \eta U$$
 and  $F = \varepsilon F \cdot F\eta$  [A.3]

characterizing adjoint situations. Then for the endofunctor

$$M = UF \colon \mathcal{K} \to \mathcal{K}$$

we have the natural transformation

$$\mu = U\varepsilon F \colon MM = UFUF \to UF = M$$
 [A.4]

which, together with the unit  $\eta: \operatorname{Id}_{\mathcal{K}} \to M$ , forms a monad on  $\mathcal{K}$ . In fact, the commutativity of the two triangles [A.2] follows from [A.3] and the square [A.1] follows from the naturality of  $\varepsilon$ :

$$\varepsilon \cdot FU\varepsilon = \varepsilon \cdot \varepsilon FU \qquad [A.5]$$

yielding

$$\mu \cdot M\mu = U(\varepsilon \cdot FU\varepsilon)F = U(\varepsilon \cdot \varepsilon FU)F = \mu \cdot \mu M.$$

Observe that whenever U is a finitary functor, this monad is finitary because F, being a left adjoint, always preserves filtered colimits.

## A.4 Example.

1. Every one-sorted algebraic category  $U: \mathcal{A} \to Set$  defines a monad on Set assigning to every set X the free algebra generated by it. In other words, this is the monad induced by the adjunction  $F \dashv U$  as in A.3, where F is the free-algebra functor of 11.21.

Since U preserves filtered colimits by 11.8, all these monads are finitary.

2. Analogously, every S-sorted algebraic category defines a finitary monad on  $Set^S$ .

**A.5 Remark.** Recall from 12.1 the category M-Alg of M-algebras for the endofunctor M of  $\mathcal{K}$ . If  $\mathbb{M}$  is the monad induced by an adjoint situation  $F \dashv U$ 

as in A.3, then every object A of  $\mathcal A$  yields a canonical  $M\text{-algebra on }X=UA\colon$  put

$$x = U\varepsilon_A \colon MX = UFUA \to UA = X$$
.

This algebra has the property that the triangle

$$\begin{array}{c|c} X & [A.6] \\ & & \\ & & \\ MX \xrightarrow{\operatorname{id}_X} X \end{array}$$

commutes: see [A.3]. Also the square

$$\begin{array}{ccc} MMX \xrightarrow{\mu_X} & MX \\ Mx & & & \\ MX & & & \\ MX & \xrightarrow{x} & X \end{array}$$
 [A.7]

commutes, see [A.5]. This leads to the following

**A.6 Definition.** An *Eilenberg-Moore algebra* for a monad  $\mathbb{M} = (M, \mu, \eta)$  on  $\mathcal{K}$  is an algebra (X, x) for M such that [A.6] and [A.7] commute. The full subcategory of M-Alg formed by all Eilenberg-Moore algebras is denoted by

 $\mathcal{K}^{\mathbb{M}}$ .

A.7 Remark. The Eilenberg-Moore category  $\mathcal{K}^{\mathbb{M}}$  is considered a concrete category on  $\mathcal{K}$  via the faithful functor

$$U_{\mathbb{M}} \colon \mathcal{K}^{\mathbb{M}} \to \mathcal{K} , \ (X, x) \mapsto X$$

It is easy to verify that this concrete category is uniquely transportable (same argument as in 13.17.3).

## A.8 Example.

- 1. For every category  $\mathcal{K}$  we have the trivial monad  $\mathbb{Id} = (\mathrm{Id}_{\mathcal{K}}, \mathrm{id}, \mathrm{id})$ . The only Eilenberg-Moore algebras are  $\mathrm{id}_X \colon X \to X$ . Thus,  $\mathcal{K}^{\mathbb{I}} \simeq \mathcal{K}$ .
- 2. For the monad MX = X + 1 of A.2.1 an Eilenberg-Moore algebra is a pointed set: given  $x: X + 1 \to X$  with [A.6], the left-hand component of x is  $id_X$ , thus, x just chooses an element  $1 \to X$ . Here [A.7] always commutes. Homomorphisms are functions preserving the choice of element. Shortly:  $Set^{\mathbb{M}}$  is the category of pointed sets.
- 3. For the word monad A.2.2 the category  $Set^{\mathbb{M}}$  is essentially the category of monoids. In fact, given an Eilenberg-Moore algebra  $x: X^* \to X$ , then [A.6] states that the response to one-letter words is trivial: x(a) = a. And

[A.7] states that for words of length larger than 2 the response is given by the binary operation

$$a_1 * a_2 = x(a_1 a_2)$$
.

In fact, for example in length 3 we get

$$x(a_1a_2a_3) = x(a_1(a_2a_3)) = a_1 * (a_2 * a_3)$$

as well as

$$x(a_1a_2a_3) = x((a_1a_2)a_3) = (a_1 * a_2) * a_3$$

Thus, \* is an associative operation. And [A.7] also states that the response of x to the empty word is a unit for x.

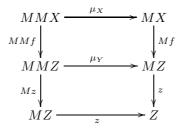

Conversely: every monoid defines an Eilenberg-Moore algebra: see Remark A.5. The monoid homomorphisms are easily seen to be precisely the homomorphisms in  $Set^{\mathbb{M}}$ . Thus,  $Set^{\mathbb{M}}$  is isomorphic to the category of monoids.

**A.9 Example.** Free Eilenberg-Moore algebras. For every monad  $\mathbb{M}$ , the *M*-algebra

$$(MX, \mu_X : MMX \to MX)$$

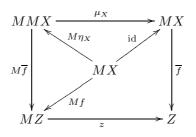

is an Eilenberg-Moore algebra: [A.6] and [A.7] follow from the definition of monad. This algebra is free with respect to  $\eta_X \colon X \to MX$ . In fact, given an Eilenberg-Moore algebra (Z, z) and a morphism  $f \colon X \to Z$  in  $\mathcal{K}$ , the unique homomorphism extending f is  $\overline{f} = z \cdot Mf$ :

(a)  $\overline{f} = z \cdot Mf$  is a homomorphism:

due to [A.5] and the naturality of  $\mu$ .

(b) Conversely, if  $\overline{f}: (MX, \mu_X) \to (Z, z)$  is a homomorphism, then  $f = \overline{f} \cdot \eta_X$  implies  $\overline{f} = z \cdot Mf$ :

A.10 Corollary. Every monad is induced by some adjoint situation.

In fact, given a monad  $\mathbb{M}$  on a category  $\mathcal{K}$ , we have the above adjoint situation

$$\mathcal{K}^{\mathbb{M}} \xrightarrow{F_{\mathbb{M}}} \mathcal{K}$$

where  $F_{\mathbb{M}}$  is the free-algebra functor

$$F_{\mathbb{M}}X = (MX, \mu_X).$$

It is defined on morphisms by  $F_{\mathbb{M}}f = Mf$ . Thus, the monad induced by the adjunction  $F_{\mathbb{M}} \dashv U_{\mathbb{M}}$  has the underlying endofunctor  $U_{\mathbb{M}} \cdot F_{\mathbb{M}} = M$ , and the unit  $\eta$  (recall the universal morphisms  $\eta_X$  above). We need to verify that for the counit  $\varepsilon$  of the adjoint situation we have

$$\mu = U_{\mathbb{M}} \varepsilon F_{\mathbb{M}} \,.$$

In fact, the component of  $\varepsilon$  at an Eilenberg-Moore algebra (X,x) is the unique morphism

$$\varepsilon_{(X,x)} \colon (MX,\mu_X) \to (X,x)$$

with  $U_{\mathbb{M}}\varepsilon_{(X,x)} \cdot \eta_X = \mathrm{id}_X$ . But due to [A.6] and [A.7] the morphism x carries such a homomorphism. Therefore,  $U_{\mathbb{M}}\varepsilon_{(X,x)} = x$  for all algebras (X, x). In particular,

$$(U_{\mathbb{M}} \varepsilon F_{\mathbb{M}})_X = U_{\mathbb{M}} \varepsilon_{(MX,\mu_X)} = \mu_X.$$

A.11 Definition. For every adjoint situation

$$\mathcal{A} \xrightarrow{F} \mathcal{K} \quad \text{with} \ F \dashv U$$

let  $\mathbb{M}$  be the monad of A.3. The *comparison functor* is the functor

$$K\colon \mathcal{A}\to \mathcal{K}^{\mathbb{M}}$$

which assigns to every object A the Eilenberg-Moore algebra

$$KA = (UA, U\varepsilon_A)$$

of A.5. The definition of K on morphisms  $f: A \to B$  uses the naturality of  $\varepsilon$  which shows that Kf = Uf is a homomorphism:

\* \*

$$\begin{array}{c} MUA \xrightarrow{U \in A} UA \\ MUf & \downarrow Uf \\ MUB \xrightarrow{U \in B} UB \end{array}$$

**A.12 Remark.** The comparison functor  $K: \mathcal{A} \to \mathcal{K}^{\mathbb{M}}$  of A.11 is the unique functor such that  $U_{\mathbb{M}} \cdot K = U$  and  $K \cdot F = F_{\mathbb{M}}$ .

#### A.13 Example.

- 1. For the concrete category of monoids  $U: Mon \to Set$  the comparison functor  $K: Mon \to Set^{\mathbb{M}}$  is an isomorphism. The inverse  $K^{-1}$  was described in A.8.2 on objects, and acts trivially on morphisms:  $K^{-1}f = f$ .
- 2. The concrete category  $U: Pos \to Set$  of partially ordered sets yields the trivial monad  $\mathbb{Id} = (\mathrm{Id}_{Set}, \mathrm{id}, \mathrm{id})$  of A.8: recall that the left adjoint of U assigns to every set X the discrete order on the same set. For this monad we have an isomorphism between Set and  $Set^{\mathbb{M}}$ , and the comparison functor is then simply the forgetful functor U.
- 3. For the free monad on H, see A.2.3, the Eilenberg-Moore category is concretely isomorphic to H-Alg. Indeed, the functor  $J: Set^{H^*} \to H$ -Alg taking an Eilenberg-Moore algebra  $x: H^*X \to X$  to the H-algebra obtained by composing with  $\psi_X$  (see A.2.3) is easily seen to be a concrete isomorphism.

**A.14 Definition.** A concrete category  $(\mathcal{A}, U)$  on  $\mathcal{K}$  is *monadic* if U has a left adjoint F and the comparison functor  $K \colon \mathcal{A} \to \mathcal{K}^{\mathbb{M}}$  is an isomorphism.

#### A.15 Remark.

- 1. The fact that  $(\mathcal{A}, U)$  is monadic does not depend on the choice of the left adjoint of U. Indeed, if F' is another left adjoint, then the canonical natural isomorphism  $F \simeq F'$  induces an isomorphism of monads  $\mathbb{M} \simeq \mathbb{M}'$  (see A.24 for the notion of monad morphism), where  $\mathbb{M}'$  is the monad induced by the adjunction  $U \dashv F'$ . As we will see in A.26, this implies that  $\mathcal{K}^{\mathbb{M}}$  and  $\mathcal{K}^{\mathbb{M}'}$  are concretely isomorphic.
- 2. In other words, monadic concrete categories are precisely those which, up to concrete isomorphism, have the form  $\mathcal{K}^{\mathbb{M}}$ . It is not surprising, then, that monoids are an example and posets are not.

**A.16 Definition.** A coequalizer in a category  $\mathcal{K}$  is called *absolute* if every functor with domain  $\mathcal{K}$  preserves it.

**A.17 Example.** For every Eilenberg-Moore algebra (X, x) we have an absolute coequalizer

$$MMX \xrightarrow{Mx} MX \xrightarrow{x} X$$

in  $\mathcal{K}$ . In fact, x merges the parallel pair by [A.7] and, moreover, the morphisms  $\eta_X$  and  $\eta_{MX}$  are easily seen to fulfil the following equations:

- (i)  $\mu_X \cdot \eta_{MX} = \mathrm{id}_{MX}$ ,
- (ii)  $\eta_X \cdot x = \mathrm{id}_X$ ,

and

(iii)  $Mx \cdot \eta_{MX} = \eta_X \cdot x.$ 

It is easy to derive from (i)–(iii) that x is a coequalizer of Mx and  $\mu_X$ . Since every functor G preserves the equations (i)–(iii), it follows that Gx is a coequalizer of GMx and  $G\mu_X$ .

A.18 Beck's Theorem. (Characterization of monadic categories) A concrete category  $(\mathcal{A}, U)$ , with U a right adjoint, is monadic if and only if

(a) it is uniquely transportable,

and

(b)  $\mathcal{A}$  has coequalizers of all reflexive pairs f, g such that Uf, Ug have an absolute coequalizer, and U preserves these coequalizers.

A proof of A.18 can be found in [68], Chapter 6, Section 7. The reader has just to observe that the parallel pairs of morphisms used in that proof are reflexive, and U creates the coequalizers involved in condition (b) since it is amnestic and conservative.

A.19 Proposition. Every equational category is monadic.

Condition (a) of A.18 follows from 13.17 and (b) from 13.11 and 11.8: Proof. the forgetful functor is algebraic, thus it preserves reflexive coequalizers. 

#### A.20 Example.

- 1. Pointed sets, monoids, groups, abelian groups, ..., with their forgetful functors are monadic.
- 2. For a one-sorted algebraic theory  $(\mathcal{T}, T)$ , the concrete category  $(Alg\mathcal{T}, AlgT)$ in general is not monadic, as Example 11.7 shows:  $AlgT_{ab}$  is not amnestic whereas  $U_{\mathbb{M}}$  always is. What remains true is that  $(Alg\mathcal{T}, AlgT)$  is pseudo-monadic, as we will see in C.4,

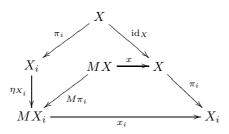

A.21 Theorem. Equational categories are up to concrete isomorphism precisely the categories  $Set^{\mathbb{M}}$  of Eilenberg-Moore algebras for finitary monads  $\mathbb{M}$  on Set.

Proof. In fact, every equational category is, by A.19, concretely isomorphic to  $Set^{\mathbb{M}}$  where  $\mathbb{M}$  is the monad of its free algebras.

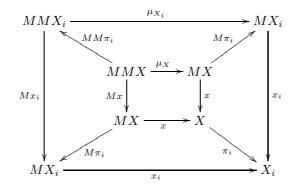

Conversely, given a finitary monad  $\mathbb{M} = (M, \mu, \eta)$  on Set, we know from 13.23 that M-Alg is concretely isomorphic to an equational category. Therefore, it is sufficient to prove that  $Set^{\mathbb{M}}$  is closed in *M*-Alg under products, subobjects, and regular quotients. Then the result follows from Birkhoff's Variety Theorem in the form 13.22.

#### APPENDIX A. MONADS

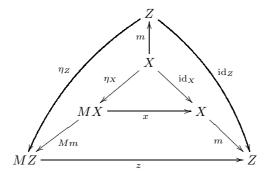

(a) Products: let  $(X, x) = \prod_{i \in I} (X_i, x_i)$  where each  $(X_i, x_i)$  is an Eilenberg-Moore algebra. (X, x) satisfies [A.6] because the projections  $(\pi_i)_{i \in I}$  are a limit cone, thus collectively monomorphic, and the diagram

commutes for every *i*. Thus  $x_i \cdot \eta_{X_i}$  = id implies  $x \cdot \eta_X$  = id. (X, x) satisfies [A.7] for similar reasons:

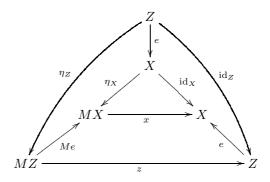

(b) Subalgebras  $m\colon (X,x)\to (Z,z)$  of Eilenberg-Moore algebras (Z,z). In the following diagram

the outward triangle commutes and all parts except the middle triangle also commute. Thus so does the middle triangle since m is a monomorphism. Therefore, (X, x) satisfies [A.6]. The proof of [A.7] is analogous.

(c) Regular quotients  $e \colon (Z, z) \to (X, x)$  of Eilenberg-Moore algebras (Z, z). In

the following diagram

again all parts except the middle triangle commute. Since e is an epimorphism, so does the middle triangle. Therefore, (X, x) satisfies [A.6]. For [A.7] use the analogous argument plus the fact that M preserves epimorphisms (because they split in *Set*).

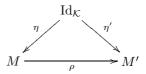

**A.22 Corollary.** One-sorted algebraic categories are up to concrete equivalence precisely the categories  $Set^{\mathbb{M}}$  of Eilenberg-Moore algebras for finitary monads  $\mathbb{M}$  on Set.

In fact, this follows from A.21 and 13.11.

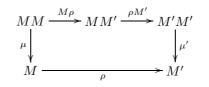

**A.23 Corollary.** For every finitary monad  $\mathbb{M}$  on Set the category Set<sup> $\mathbb{M}$ </sup> is cocomplete and the forgetful functor  $U_{\mathbb{M}} \colon Set^{\mathbb{M}} \to Set$  preserves sifted colimits.

In fact, the category  $Set^{\mathbb{M}}$  is equational by A.21 and then one-sorted algebraic by 13.11. Use now 4.5 and 11.9.

**A.24 Definition.** Let  $\mathbb{M} = (M, \mu, \eta)$  and  $\mathbb{M}' = (M', \mu', \eta')$  be monads on a category  $\mathcal{K}$ . A monad morphism from  $\mathbb{M}$  to  $\mathbb{M}'$  is a natural transformation  $\rho: M \to M'$  such that the diagrams

and

commute.

#### APPENDIX A. MONADS

**A.25 Example.** Let M be any endofunctor of *Set.* Following 4.11 and 4.13 there exists a finitary endofunctor  $M^f$  and a natural transformation  $\epsilon^M : M^f \to M$  universal among the natural transformations  $N \to M$  with N finitary. If M is part of a monad  $\mathbb{M} = (M, \mu, \eta)$ , then  $M^f$  becomes part of a finitary monad and  $\epsilon^M$  a monad morphism: the monad multiplication for  $M^f$  is

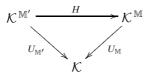

$$M^f \cdot M^f \xrightarrow{i} (M \cdot M)^f \xrightarrow{\mu^f} M^f$$

where  $\mu^f$  is the unique natural transformation with  $\epsilon^M \cdot \mu^f = \mu \cdot \epsilon^{MM}$  and *i* is the unique natural isomorphism with  $i_n = \text{id}$  for all  $n \in \mathcal{N}$ , and analogously for the monad unit.

**A.26 Proposition.** Every monad morphism  $\rho: \mathbb{M} \to \mathbb{M}'$  induces a concrete functor

$$H_o: \mathcal{K}^{\mathbb{M}'} \to \mathcal{K}^{\mathbb{M}}$$

assigning to every Eilenberg-Moore algebra (X, x) for  $\mathbb{M}'$  the algebra  $(X, x \cdot \rho_X)$  for  $\mathbb{M}$ . Conversely, given a concrete functor

there exists a unique monad morphism  $\rho \colon \mathbb{M} \to \mathbb{M}'$  with  $H = H_{\rho}$ .

In fact, for a free Eilenberg-Moore algebra  $(M'A, \mu'_A)$ , the algebra  $H(M'A, \mu'_A)$  has the form  $(M'A, \sigma_A \colon MM'A \to M'A)$ . We get a monad morphism

$$\rho \colon \mathbb{M} \to \mathbb{M}', \ \rho_A \colon MA \xrightarrow{M\eta'_A} MM'A \xrightarrow{\sigma_A} M'A.$$

A full proof can be found in [28], Vol. 2, Proposition 4.5.9.

**A.27 Corollary.** The category of finitary monads on Set and monad morphisms is dually equivalent to the category of finitary monadic categories on Set and concrete functors.

In fact, this follows from A.26.

**A.28 Corollary.** The free monad on a finitary endofunctor (see A.2.3) is indeed free on H: for every finitary monad  $\mathbb{M} = (M, \mu, \eta)$  and every natural transformation  $\alpha: H \to M$  there exists a unique monad morphism  $\alpha^*: H^* \to M$  with  $\alpha = \alpha^* \cdot \psi$ .

In fact, recall from A.13.3 that *H*-*Alg* is concretely isomorphic to  $Set^{H^*}$  and use, in place of  $\alpha^*$ , the concrete functor from  $Set^{\mathbb{M}}$  to *H*-*Alg* assigning to every Eilenberg-Moore algebra  $x: MX \to X$  the algebra  $x \cdot \alpha_X : HX \to X$ .

**A.29 Remark.** We observed above that every monad  $\mathbb{M}$  is induced by an adjoint situation using the Eilenberg-Moore algebras. There is another way to induce  $\mathbb{M}$ : the construction of the Kleisli category of  $\mathbb{M}$ . This is, as we note below, just the full subcategory of  $\mathcal{K}^{\mathbb{M}}$  on all free algebras:

A.30 Definition. The *Kleisli category* of a monad M is the category

 $\mathcal{K}_{\mathbb{M}}$ 

with the same objects as  $\mathcal{K}$  and with morphisms from X to Z given by morphisms  $f: X \to MZ$  in  $\mathcal{K}$ :

$$\mathcal{K}_{\mathbb{M}}(X,Z) = \mathcal{K}(X,MZ) \,.$$

The identity morphisms are  $\eta_X$  and the composition of two morphisms  $f \in \mathcal{K}_{\mathbb{M}}(X, Z)$  and  $g \in \mathcal{K}_{\mathbb{M}}(Z, W)$  is given by the following composition in  $\mathcal{K}$ :

$$X \xrightarrow{f} MZ \xrightarrow{Mg} MMW \xrightarrow{\mu_W} MW$$

**A.31 Example.** For the monad MX = X + 1 of A.2.1 the Kleisli category is the category of sets and partial functions. A partial function from X to Z is represented as a (total) function from X to Z + 1.

A.32 Notation. For every monad  $\mathbb{M}$  we denote

1. by  $K_{\mathbb{M}} \colon \mathcal{K}_{\mathbb{M}} \to \mathcal{K}^{\mathbb{M}}$  the functor which assigns to  $X \in \mathcal{K}_{\mathbb{M}}$  the free Eilenberg-Moore algebra  $(MX, \mu_X)$  and to  $f \in \mathcal{K}_{\mathbb{M}}(X, Z)$  the morphism

$$MX \xrightarrow{Mf} MMZ \xrightarrow{\mu_Z} MZ$$

2. by  $J_{\mathbb{M}} \colon \mathcal{K} \to \mathcal{K}_{\mathbb{M}}$  the functor which is the identity map on objects and which to every morphism  $u \colon X \to Z$  of  $\mathcal{K}$  assigns

$$X \xrightarrow{u} Z \xrightarrow{\eta_Z} MZ$$

A.33 Lemma. The functor  $J_{\mathbb{M}}$  is a left adjoint of

$$\mathcal{K}_{\mathbb{M}} \xrightarrow{K_{\mathbb{M}}} \mathcal{K}^{\mathbb{M}} \xrightarrow{U_{\mathbb{M}}} \mathcal{K}$$

and  $\mathbb{M}$  is the monad induced by the adjunction  $J_{\mathbb{M}} \dashv U_{\mathbb{M}} \cdot K_{\mathbb{M}}$ . The functor  $K_{\mathbb{M}}$  is the corresponding comparison functor; it is full and faithful.

**Proof.**  $J_{\mathbb{M}}$  is a left adjoint of  $U_{\mathbb{M}} \cdot K_{\mathbb{M}}$  with unit

$$\eta_X \colon X \to MX = U_{\mathbb{M}} K_{\mathbb{M}} J_{\mathbb{M}} X$$

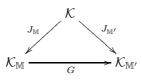

and counit given by the morphism in  $\mathcal{K}_{\mathbb{M}}(J_{\mathbb{M}}U_{\mathbb{M}}K_{\mathbb{M}}X, X)$  which is  $\varepsilon = \mathrm{id}_{MX}$  in  $\mathcal{K}$ . The two axioms

$$\varepsilon J_{\mathbb{M}} \cdot J_{\mathbb{M}} \eta = J_{\mathbb{M}}$$
 and  $U_{\mathbb{M}} K_{\mathbb{M}} \varepsilon \cdot \eta U_{\mathbb{M}} K_{\mathbb{M}} = U_{\mathbb{M}} K_{\mathbb{M}}$ 

are easy to check.

#### APPENDIX A. MONADS

**A.34 Theorem.** Given monads  $\mathbb{M}$  and  $\mathbb{M}'$  on a category  $\mathcal{K}$ , there is a bijective correspondence between monad morphisms  $\rho \colon \mathbb{M} \to \mathbb{M}'$  and functors  $G \colon \mathcal{K}_{\mathbb{M}} \to \mathcal{K}_{\mathbb{M}'}$  for which the triangle

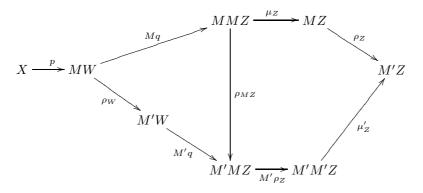

commutes.

We will see in the proof that the bijective correspondence assigns to every monad morphism  $\rho: \mathbb{M} \to \mathbb{M}'$  the functor  $\hat{\rho}: \mathcal{K}_{\mathbb{M}} \to \mathcal{K}_{\mathbb{M}'}$  which is the identity map on objects, and assigns to  $p: X \to MZ$  in  $\mathcal{K}_{\mathbb{M}}(X, Z)$  the value

$$X \xrightarrow{p} MZ \xrightarrow{\rho_Z} M'Z$$

**Proof.** (a)  $\hat{\rho}$  is well-defined: Preservation of identity morphisms follows from  $\rho_X \cdot \eta_X = \eta'_X$ . Preservation of composition follows from the commutativity of the diagram below, where  $p: X \to MW$  and  $q: W \to MZ$  are arbitrary morphisms:

(b) The equality  $\hat{\rho} \cdot J_{\mathbb{M}} = J_{\mathbb{M}'}$  follows from  $\rho \cdot \eta = \eta'$ .

(c) If  $\rho, \sigma$  are different monad morphisms, then  $\hat{\rho} \neq \hat{\sigma}$  due to the fact that the component  $\rho_X$  is obtained from  $\hat{\rho}$  by  $\hat{\rho}(\mathrm{id}_{MX}) = \rho_X$ .

(d) Let  $G: \mathcal{K}_{\mathbb{M}} \to \mathcal{K}_{\mathbb{M}'}$  be a functor such that  $G \cdot J_{\mathbb{M}} = J_{\mathbb{M}'}$ . Observe that this condition tells us that G is the identity map on objects. The identity morphism  $\mathrm{id}_{MX}: MX \to MX$  can be seen as a morphism  $\varepsilon_X: MX \to X$  in  $\mathcal{K}_{\mathbb{M}}$ . Applying G we get a morphism  $G\varepsilon_X: MX \to X$  in  $\mathcal{K}_{\mathbb{M}'}$ , that is, a morphism  $MX \to M'X$  in  $\mathcal{K}$  that we denote by  $\rho_X$ . We claim that  $\rho_X$  is the component at X of a monad morphism  $\rho: \mathbb{M} \to \mathbb{M}'$  with  $\hat{\rho} = G$ .

The fact that G is a functor means that

- (i)  $G\eta_X = \eta'_X$  (preservation of identity morphisms)
- (ii) given  $p: X \to MW$  and  $q: W \to MZ$  in  $\mathcal{K}$  we have

$$G(X \xrightarrow{p} MW \xrightarrow{Mq} MMZ \xrightarrow{\mu_Z} MZ) =$$

$$= \left( \begin{array}{cc} X \xrightarrow{\quad Gp \quad} M'W \xrightarrow{\quad M'Gq} M'M'Z \xrightarrow{\quad \mu_Z'} M'Z \end{array} \right)$$

(preservation of composition)

and

(iii) for every  $u: X \to W$  in  $\mathcal{K}$  we have

$$G(X \xrightarrow{u} W \xrightarrow{\eta_W} MW) = (X \xrightarrow{u} W \xrightarrow{\eta'_W} M'W)$$

(due to  $G \cdot J_{\mathbb{M}} = J_{\mathbb{M}'}$ ).

This implies for all  $u: X \to W$  in  $\mathcal{K}$  the equation

(iv)  $GMu = Gu \cdot \rho_X$ 

since we apply (ii) to  $p = \mathrm{id}_{MX}$  and  $q = \eta_W \cdot u$  (thus the previous objects X, W and Z are now MX, X and W, respectively, and  $Gq = \eta'_W \cdot u$  by (iii)) and use [A.2] for M and M'. Also for every  $q: W \to MZ$  we have

(v)  $G(q \cdot u) = Gq \cdot u$ 

by applying (ii) and (iii) to  $p = \eta_W \cdot u$ . From this we derive the naturality of  $\rho$ :

(vi)  $\rho_W \cdot Mv = M'v \cdot \rho_X$  for all  $v: X \to W$ 

since (v) yields for  $q = id_{MW}$  and u = Mv

$$\rho_W \cdot Mv = GMv$$

and then we apply (iv). The equality  $\rho \cdot \eta = \eta'$  follows from (v) by  $u = \eta_W$  and  $q = \mathrm{id}_{MW}$ , and the equality  $\rho \cdot \mu = \mu' \cdot \rho M' \cdot M\rho$  follows from (ii) by  $p = \mathrm{id}_{MMX}$  and  $q = \mathrm{id}_{MX}$ ; this proves that the right-hand side is equal to  $G\mu_X$ , whereas the left-hand side is  $G\mu_X$  by (v) applied to  $q = \mu_X$  and  $u = \mathrm{id}_{MMX}$ . Thus,

$$\rho \colon \mathbb{M} \to \mathbb{M}$$

is a monad morphism. Finally we need to prove  $\hat{\rho} = G$ , that is, for every  $p_0: X \to MW$ 

$$Gp_0 = G\varepsilon_X \cdot p_0$$

and for this apply (v) to  $u = p_0$  and  $q = id_{MW}$ .

**A.35 Remark.** Let  $\mathbb{M}$  be a finitary monad on *Set.* Then the functor M is essentially determined by its domain restriction to  $\mathcal{N}^{op}$  (the full subcategory of natural numbers). Also the natural transformations  $\eta$  and  $\mu$  are uniquely determined by their components  $\eta_n$  and  $\mu_n$  for natural numbers n. In fact, this follows from 4.11 applied to  $Y_{\mathcal{N}} : \mathcal{N}^{op} \to Set$ .

This leads us to the following restriction of the Kleisli category:

**A.36 Notation.** For every finitary monad  $\mathbb{M}$  on *Set* we denote by

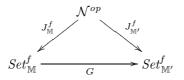

$$Set^f_{\mathbb{M}}$$

the full subcategory of the Kleisli category  $\mathcal{K}_{\mathbb{M}}$  on all natural numbers, and by

$$J^f_{\mathbb{M}} \colon \mathcal{N}^{op} \to Set^f_{\mathbb{M}}$$

the domain-codomain restriction of  $J_{\mathbb{M}}$ .

**A.37 Corollary.** Given finitary monads  $\mathbb{M}$  and  $\mathbb{M}'$  on Set, there is a bijective correspondence between monad morphisms  $\rho \colon \mathbb{M} \to \mathbb{M}'$  and those functors  $G \colon \operatorname{Set}^f_{\mathbb{M}} \to \operatorname{Set}^f_{\mathbb{M}'}$  for which the triangle

commutes. It assigns to  $\rho$  the functor

$$\hat{\rho}^f \colon ( \begin{array}{cc} n \xrightarrow{p} Mk \end{array}) \mapsto ( \begin{array}{cc} n \xrightarrow{p} Mk \xrightarrow{\rho_k} M'k \end{array})$$

The proof is completely analogous to that of A.34. All we need to notice is that a monad morphism  $\rho \colon \mathbb{M} \to \mathbb{M}'$  is uniquely determined by its components  $\rho_n, n \in \mathcal{N}^{op}$ . This follows once again from 4.11 applied to  $Y_{\mathcal{N}} \colon \mathcal{N}^{op} \to Set$ .

In 11.35 we defined the 2-category  $Th^{1}$  of one-sorted algebraic theories. In the following theorem we consider it as a category, that is, we forget the 2-cells.

**A.38 Theorem.** The category  $Th^1$  of one-sorted algebraic theories is equivalent to the category of finitary monads on Set.

**Proof.** Denote by *FMon* the category of finitary monads and monad morphisms. Every object  $\mathbb{M}$  defines a one-sorted theory by dualizing  $J^f_{\mathbb{M}}$  of A.36:

$$(J^f_{\mathbb{M}})^{op} \colon \mathcal{N} \to (Set^f_{\mathbb{M}})^{op}$$

In fact, since  $J_{\mathbb{M}} \colon Set \to Set_{\mathbb{M}}$  is a left adjoint, it preserves coproducts. In other words, coproducts are the same in Set and in  $Set_{\mathbb{M}}$ . The same, then, holds for finite coproducts in the full subcategories  $\mathcal{N}^{op}$  and  $Set_{\mathbb{M}}^{f}$ , respectively. Therefore, the identity-on-objects functor  $(J_{\mathbb{M}}^{f})^{op}$  preserves finite products and we obtain a one-sorted theory

$$E(\mathbb{M}) = \left( (Set^f_{\mathbb{M}})^{op}, (J^f_{\mathbb{M}})^{op} \right) \,.$$

This yields a functor

 $E \colon FMon \to Th^1$ 

which to every monad morphism  $\rho \colon \mathbb{M} \to \mathbb{M}'$  between finitary monads assigns

$$E(\rho) = (\hat{\rho}^f)^{op}$$

The commutative triangle of A.37 tells us that this is a morphism of one-sorted theories. It is easy to verify that E is a well-defined functor.

Next E is full and faithful due to the bijection in A.37. Finally, E is essentially surjective. Recall from 11.21 that for every one-sorted theory  $(\mathcal{T}, T)$  we have a left adjoint  $F_T$  to the forgetful functor AlgT (of evaluation at 1) such that

$$F_T(n) = \mathcal{T}(n, -)$$
 and  $F_T(\pi_i^n) = -\cdot T\pi_i^n$ 

Moreover, the naturality square for  $\eta$ : Id  $\rightarrow AlgT \cdot F_T$  applied to  $\pi_i^n$  yields

$$\eta_n(i) = T \pi_i^n$$
 for all  $i = 0, ..., n-1$ .

Let  $\mathbb{M}$  be the monad corresponding to this adjoint situation. We know that  $\mathbb{M}$  is finitary and the values at  $n \in \mathcal{N}$  are

$$Mn = \mathcal{T}(n, 1) \,.$$

The theory  $(Set^{f}_{\mathbb{M}})^{op}$  thus has as morphisms from n to k precisely all functions

$$p: k \to \mathcal{T}(n, 1)$$
.

This k-tuple of morphisms defines a unique morphism

$$Ip \in \mathcal{T}(n,k)$$

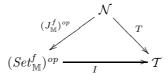

characterized by

$$T\pi_i^k \cdot Ip = p(i) \ (i = 0, \dots, k-1).$$

We obtain an isomorphism of categories

$$I\colon (Set^f_{\mathbb{M}})^{op} \to \mathcal{T}$$

and it remains to prove that the triangle

commutes. Given a morphism  $u \in \mathcal{T}(n,k),$  then Tu is the unique morphism with

$$T\pi_i^k \cdot Tu = T\pi_{u(i)}^n$$

for all i. And we have

$$T\pi_i^n \cdot (I \cdot (J_{\mathbb{M}}^f)^{op}(u)) = T(\pi_i^k)I(\eta_n \cdot u) = \eta_n \cdot u(i) = \pi_{u(i)}^n .$$

212

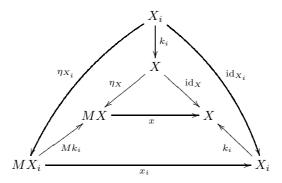

#### APPENDIX A. MONADS

**A.39 Remark.** Explicitly, the functor assigning to every one-sorted algebraic theory  $(\mathcal{T}, T)$  its monad of free  $\mathcal{T}$ -algebras is an equivalence functor from  $Th^1$  to *FMon*. In fact, this functor is a quasi-inverse of the equivalence functor E of the preceding proof.

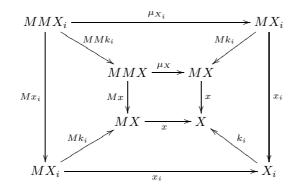

**A.40 Remark.** The situation with S-sorted theories and S-sorted algebraic categories is entirely analogous: all the above results translate without problems from Set to Set<sup>S</sup>, only Theorem A.21 needs some work:

**A.41 Theorem.** S-sorted equational categories are up to concrete isomorphism precisely the categories  $(Set^S)^{\mathbb{M}}$  of Eilenberg-Moore algebras for finitary monads  $\mathbb{M}$  on  $Set^S$ .

**Proof.** The only difference with respect to the proof of A.21 is that in the S-sorted case we have to check also that  $(Set^S)^{\mathbb{M}}$  is closed in M-Alg under directed unions. Let  $k_i: (X_i, x_i) \to (X, x)$   $(i \in I)$  be a colimit cocone of a filtered colimit in M-Alg, where each  $(X_i, x_i)$  is an Eilenberg-Moore algebra. Then (X, x) satisfies [A.6] because the cocone  $(k_i)$  is collectively epimorphic:

And it satisfies [A.7] because the cocone  $(MMk_i)$  is collectively epimorphic being a colimit cocone (since MM preserves filtered colimits):

**A.42 Theorem.** The category  $Th^{S}$  of S-sorted algebraic theories is equivalent to the category of finitary monads on  $Set^{S}$ .

The proof is completely analogous to the proof in the one-sorted case. We just observe that the functor  $J \colon Set^S \to (Set^S)^{\mathbb{M}}$  can, in case of M finitary, be restricted to  $J^f \colon (S^*)^{op} \to (Set^S)^f_{\mathbb{M}}$  analogously to A.36.

### Appendix B

## Abelian categories

Another important topic not treated in our book are abelian categories. In this appendix we restrict ourselves to introducing the basic concepts, and proving that the only one-sorted algebraic categories which are abelian are the categories R-Mod of left modules over rings R. We also prove the many-sorted generalization of this result.

**B.1 Remark.** In the following we use the standard terminology of the theory of abelian categories:

- 1. A zero object is an object 0 which is initial as well terminal. For two objects A, B the composite  $A \to 0 \to B$  is denoted by  $0: A \to B$ .
- 2. A *biproduct* of objects A and B is a product  $A \times B$  with the property that the morphisms

 $(\mathrm{id}_A, 0) : A \to A \times B \text{ and } (0, \mathrm{id}_B) : B \to A \times B$ 

form a coproduct of A and B.

- 3. A category is called *preadditive* if it is enriched over the category Ab of abelian groups, i.e., if every hom-set carries the structure of an abelian group such that composition is a group homomorphism.
- 4. In a preadditive category, an object is a zero object iff it is terminal, and a product of two objects is a biproduct. A preadditive category with finite products is called *additive*.
- 5. A functor  $F: \mathcal{A} \to \mathcal{A}'$  between preadditive categories is called *additive* if it is enriched over Ab, i.e., the derived functions  $\mathcal{A}(A, B) \to \mathcal{A}'(FA, FB)$ are group homomorphisms. In case of additive categories this is equivalent to F preserving finite products.
- 6. Finally, a category is called *abelian* if it is exact and additive.

**B.2 Example.** Just as one-object categories are precisely the monoids, oneobject preadditive categories are precisely the unitary rings R. Every left Rmodule M defines an additive functor  $\overline{M}: R \to Ab$  with  $\overline{M}(*) = M$  and  $\overline{M}r =$  $r \cdot -: M \to M$  for  $r \in R$ . Conversely, every additive functor  $F: R \to Ab$  is naturally isomorphic to  $\overline{M}$  for M = F(\*).

For a small, preadditive category C, we denote by Add [C, Ab] the abelian category of all additive functors into Ab (and all natural transformations). The previous example implies that R-Mod is equivalent to Add [R, Ab].

**B.3 Theorem.** Abelian algebraic categories are precisely those equivalent to

$$Add [\mathcal{C}, Ab]$$

for a small additive category  $\mathcal{C}$ .

**Proof.** Sufficiency. For every small additive category C, we prove that the category Add[C, Ab] is equivalent to Alg C. We denote by  $hom(C, -): C \to Set$  and  $Hom(C, -): C \to Ab$  the hom-functors. Consider the forgetful functor  $U: Ab \to Set$ . Since U preserves finite products, it induces a functor

$$\widehat{U} = U \cdot - : Add [\mathcal{C}, Ab] \to Alg \mathcal{C}$$

Let us prove that  $\widehat{U}$  is an equivalence functor.

(a)  $\hat{U}$  is faithful. This is obvious, because U is faithful.

(b)  $\widehat{U}$  is full. In fact, we first observe that  $\widehat{U}$  preserves sifted colimits. This follows from the fact that sifted colimits commute in Ab (as in any algebraic category, see 2.7) with finite products, and the functor  $U = \hom(\mathbb{Z}, -)$  preserves sifted colimits. We first verify that  $\widehat{U}$  is full for morphisms (natural transformations)

$$\alpha \colon \widehat{U}(\operatorname{Hom}(C, -)) \to \widehat{U}G$$

where  $C \in \text{obj} \mathcal{C}$  and  $G: \mathcal{C} \to Ab$  is additive. By the Yoneda Lemma, for all  $X \in \mathcal{C}$  and for all  $x: C \to X$ , we have  $\alpha_X(x) = Gx(a)$ , where  $a = \alpha_C(\text{id}_C)$ , thus,  $\alpha_X$  is a group homomorphism. Consequently,  $\alpha$  lies in the image of  $\hat{U}$ . The general case of a morphism  $\beta: \hat{U}F \to \hat{U}G$  reduces to the previous one by using the fact that F is a sifted colimit of representables and that  $\hat{U}$  preserves sifted colimits. To see that F is a filtered colimit of representables, observe that, following 4.2,  $\hat{U}F$  is a sifted colimit of representables. Now

$$\widehat{U}F = colim \operatorname{hom}(C_i, -) = colim (U \cdot \operatorname{Hom}(C_i, -)) =$$

$$= \operatorname{colim} U(\operatorname{Hom}(C_i, -)) = U(\operatorname{colim} \operatorname{Hom}(C_i, -)).$$

This implies  $F = colim \operatorname{Hom}(C_i, -)$  because  $\widehat{U}$  reflects sifted colimits (since it preserves sifted colimits and reflects isomorphisms).

(c) U is essentially surjective. We first take the representable functors hom(C, -)

for  $C \in \text{obj}\mathcal{C}$ , which are objects of  $Alg \mathcal{C}$ . Since  $\mathcal{C}$  is preadditive, for every object C' the hom-set hom(C, C') is an abelian group, and hom(C, -) factorizes as

 $\mathcal{C} \xrightarrow{\operatorname{Hom}(C,-)} Ab \xrightarrow{U} Set$ 

with  $\operatorname{Hom}(C, -) \colon \mathcal{C} \to Ab$  additive. Therefore,  $\widehat{U}(\operatorname{Hom}(C, -)) \simeq \operatorname{hom}(C, -)$ . Once again, the general case follows from the previous one by using the fact that any  $\mathcal{C}$ -algebra is a sifted colimit of representable  $\mathcal{C}$ -algebras and that  $\widehat{U}$  preserves sifted colimits.

Necessity. Let  $\mathcal{T}$  be an algebraic theory, and assume that  $Alg \mathcal{T}$  is abelian. Since  $\mathcal{T}^{op}$  embeds into  $Alg \mathcal{T}, \mathcal{T}$  is preadditive (with finite products), and then it is a small additive category. Following the first part of the proof,  $Alg \mathcal{T}$  is equivalent to  $Add [\mathcal{T}, Ab]$ .

**B.4 Corollary.** Abelian algebraic categories are precisely the additive cocomplete categories with a strong generator consisting of perfectly presentable objects.

In fact, this follows from 6.9 and B.3.

**B.5 Remark.** In B.3 the condition that C is additive can be weakened: preadditivity is enough. In fact, let C be a small preadditive category. We can construct the small and preadditive category Mat(C) of matrices over C as follows:

- Objects are finite (possibly empty) families  $(X_i)_{i \in I}$  of objects of C;
- Morphisms from  $(X_i)_{i \in I}$  to  $(Z_j)_{j \in J}$  are matrices  $M = (m_{i,j})_{(i,j) \in I \times J}$  of morphisms  $m_{i,j} \colon X_i \to Z_j$  in  $\mathcal{C}$ ;
- The matrix multiplication, the identity matrices, and matrix addition, as well known from Linear Algebra, define the composition, the identity morphisms and the preadditive structure, respectively.

This new category  $Mat(\mathcal{C})$  is additive. Indeed, it has a zero object given by the empty family, and biproducts  $\oplus$  given by disjoint unions. Let us check that the obvious embedding  $\mathcal{C} \to Mat(\mathcal{C})$  induces an equivalence between  $Add[Mat(\mathcal{C}), Ab]$  and  $Add[\mathcal{C}, Ab]$ . Indeed, given  $F \in Add[\mathcal{C}, Ab]$ , we get an extension  $F' \in Add[Mat(\mathcal{C}), Ab]$  in the following way: F'(M) is the unique morphism such that the following square

commutes for all  $(i, j) \in I \times J$ , where the vertical morphisms are injections in the coproduct and projections from the product, respectively. It is easy to verify that the functor  $F \mapsto F'$  is an equivalence from Add [C, Ab] to Add [Mat(C), Ab].

**B.6 Remark.** Observe that an object G of an additive, cocomplete category  $\mathcal{A}$  is perfectly presentable iff its enriched hom-functor  $\operatorname{Hom}(G, -): \mathcal{A} \to Ab$  preserves colimits. (Compare with the absolutely presentable objects of 5.8.) In fact, if G is perfectly presentable, then  $\operatorname{Hom}(G, -)$  preserves finite coproducts (because they are finite products) and reflexive coequalizers (because  $U: Ab \to Set$  reflects them). This implies that  $\operatorname{Hom}(G, -)$  preserves finite colimits. Indeed, given a parallel pair  $a, b: X \rightrightarrows Z$  in  $\mathcal{A}$ , its coequalizer is precisely the coequalizer of the reflexive pair  $(a, \operatorname{id}_Z), (b, \operatorname{id}_Z): X + Z \rightrightarrows Z$ . Finally,  $\operatorname{Hom}(G, -)$  preserves arbitrary colimits because they are filtered colimits of finite colimits.

**B.7 Example.** The group  $\mathbb{Z}$  is perfectly presentable in *Ab*. Indeed,

$$\operatorname{Hom}(\mathbb{Z},-)\colon Ab \to Ab$$

is naturally isomorphic to the identity functor. Observe that  $\mathbb Z$  is of course not absolutely presentable.

**B.8 Corollary.** One-sorted abelian algebraic categories are precisely the categories equivalent to R-Mod for a unitary ring R.

**Proof.** Following B.3, a one-sorted abelian algebraic category  $\mathcal{A}$  is of the form  $Add [\mathcal{T}, Ab]$  for  $\mathcal{T}$  a one-sorted additive algebraic theory with objects  $T^n$   $(n \in \mathbb{N})$ . Any  $F \in Add [\mathcal{T}, Ab]$  restricts to an additive functor  $\mathcal{T}(T, T) \to Ab$ , where the ring  $\mathcal{T}(T, T)$  is seen as a preadditive category with a single object. Moreover, F is uniquely determined by such a restriction, because each object of  $\mathcal{T}$  is a finite product of T. Finally,  $Add [\mathcal{T}(T, T), Ab]$  is equivalent to  $\mathcal{T}(T, T)$ -Mod.  $\Box$ 

**B.9 Corollary.** Finitary localizations of abelian algebraic categories are precisely the abelian locally finitely presentable categories.

**Proof.** Let  $\mathcal{A}$  be an abelian, locally finitely presentable category. Following the proof of 18.10, we have that  $\mathcal{A} = Lex\mathcal{T}$  is a finitary localization of  $Alg\mathcal{T}$ , with  $\mathcal{T}$  an additive algebraic theory. Due to B.3,  $Alg\mathcal{T}$  is equivalent to  $Add[\mathcal{T}, Ab]$ .

### Appendix C

# More about dualities for one-sorted algebraic categories

Throughout our book we took the "strict view" of what a theory morphism or a concrete functor or a monadic functor etc. should be. That is, the condition put on the functor in question was formulated as equality between two functors. There is a completely natural "non-strict view" where the conditions are formulated as natural equivalences between functors. This has a number of advantages. For example, we can present a characterization of one-sorted algebraic categories (see Theorem C.6 below) for which we know no analogous result in the strict variant. Also the duality between one-sorted algebraic theories and uniquely transportable one-sorted algebraic categories can be directly derived from the non-strict version of the biduality 11.38 without using monads. In the present appendix we shortly mention the non-strict variants of some concepts in our book.

#### C.1 Definition.

- 1. Given concrete categories  $U: \mathcal{A} \to \mathcal{K}$  and  $V: \mathcal{B} \to \mathcal{K}$  by a *pseudo-concrete* functor between them we mean a functor  $F: \mathcal{A} \to \mathcal{B}$  such that  $V \cdot F$  is naturally isomorphic to U.
- 2. Given concrete categories  $U: \mathcal{A} \to \mathcal{K}$  and  $V: \mathcal{B} \to \mathcal{K}$  by a *pseudo-concrete* equivalence between them we mean a functor  $F: \mathcal{A} \to \mathcal{B}$  which is at the same time an equivalence and pseudo-concrete. (Note that any quasi-inverse of F is necessarily pseudo-concrete.) We then say that  $(\mathcal{A}, U)$  and  $(\mathcal{B}, V)$  are *pseudo-concretely equivalent*.

**C.2 Definition.** A concrete category  $(\mathcal{A}, U)$  on  $\mathcal{K}$  is *pseudo-monadic* if there exists a monad  $\mathbb{M}$  on  $\mathcal{K}$  and a pseudo-concrete equivalence  $\mathcal{A} \to \mathcal{K}^{\mathbb{M}}$ .

**C.3 Beck's Theorem.** (Characterization of pseudo-monadic categories) A concrete category  $(\mathcal{A}, U)$ , is pseudo-monadic if and only if

- (a) U has a left adjoint,
- (b) U is conservative,

and

(c)  $\mathcal{A}$  has coequalizers of all reflexive pairs f, g such that Uf, Ug have an absolute coequalizer, and U preserves these coequalizers.

A proof of C.3 can be found in [28], Chapter 4, Section 4. The reader needs just to observe that the parallel pairs of morphisms used in that proof are reflexive.

**C.4 Proposition.** For every one-sorted algebraic theory  $(\mathcal{T}, T)$ , the concrete category  $(Alg\mathcal{T}, AlgT)$  is pseudo-monadic.

**Proof.** The functor AlgT is algebraic and conservative (11.8), and algebraic functors are right adjoint and preserve reflexive coequalizers. Following C.3, (AlgT, AlgT) is pseudo-monadic.

**C.5 Definition.** A pseudo-one-sorted algebraic category is a concrete category over Set which is pseudo-concretely equivalent to  $AlgT: AlgT \rightarrow Set$  for a one-sorted algebraic theory  $(\mathcal{T}, T)$ .

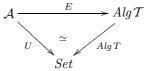

**C.6 Theorem.** (Characterization of pseudo-one-sorted algebraic categories) The following conditions on a concrete category  $(\mathcal{A}, U)$  over Set are equivalent:

- 1.  $(\mathcal{A}, U)$  is pseudo-one-sorted algebraic;
- 2. A is cocomplete and U is a conservative right adjoint preserving sifted colimits.

More detailed: let  $\mathcal{A}$  be a cocomplete category. Given a faithful functor

$$U \colon \mathcal{A} \to Set$$

with  $\mathcal{A}$  cocomplete, there exists a one-sorted algebraic theory  $(\mathcal{T}, T)$  and an equivalence functor

making the above diagram commutative up to natural isomorphism iff U is a conservative right adjoint preserving sifted colimits.

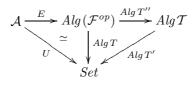

**Proof.** The conditions are necessary by 11.8. Let us prove that they are sufficient: let  $U: \mathcal{A} \to Set$  be as above, with F a left adjoint of U. The set  $\mathcal{F} = \{Fn : n \in \mathbb{N}\}$  is closed in  $\mathcal{A}$  under finite coproducts and, by 6.16, it is a

February 1, 2010 2

strong generator formed by perfectly presentable objects. Following the proof of 6.9 (implication  $3 \Rightarrow 1$ ), the functor

$$E: \mathcal{A} \to Alg(\mathcal{F}^{op}), \quad K \mapsto \mathcal{A}(-,K): \mathcal{F}^{op} \to Set$$

is an equivalence. Moreover, the codomain restriction  $T: \mathcal{N} \to \mathcal{F}^{op}$  of the functor  $F^{op} \cdot Y_{\mathcal{N}}: \mathcal{N} \to \mathcal{A}^{op}$  is a morphism of theories. Let us check that there exists a natural isomorphism  $AlgT \cdot E \simeq U$ : for every  $A \in \mathcal{A}$  and  $n \in \mathbb{N}$  the functor  $AlgT \cdot E(A)$  assigns to  $n \in \mathbb{N}$  the set  $\mathcal{A}(Tn, A)$ , and since  $Tn = F(Y_{\mathcal{N}}(n))$ , the adjunction  $F \dashv U$  clearly yields a natural isomorphism  $\mathcal{A}(Tn, A) \simeq UA(n)$ . Factorize T as a functor  $T': \mathcal{N} \to \mathcal{T}$  which is the identity on objects and equal to T on morphisms, followed by a functor  $T'': \mathcal{T} \to \mathcal{F}^{op}$  which is the identity on morphisms and equal to T on objects. Therefore, T'' is an equivalence (because T is surjective on objects) and  $(\mathcal{T}, T')$  is a one-sorted theory. The following diagram concludes the proof:

**C.7 Corollary.** Pseudo-one-sorted algebraic categories are up to pseudo-concrete equivalence precisely the categories  $Set^{\mathbb{M}}$  of Eilenberg-Moore algebras for finitary monads  $\mathbb{M}$  on Set.

In fact, this follows from C.4, C.6 and A.23.

It is easy to extend the biequivalence of Theorem 11.38 to pseudo-one-sorted algebraic categories.

**C.8 Definition.** Given one-sorted algebraic theories  $(\mathcal{T}_1, \mathcal{T}_1)$  and  $(\mathcal{T}_2, \mathcal{T}_2)$ , a pseudo-morphism

$$M\colon (\mathcal{T}_1, T_1) \to (\mathcal{T}_2, T_2)$$

is a functor  $M: \mathcal{T}_1 \to \mathcal{T}_2$  with  $M \cdot T_1$  naturally isomorphic to  $T_2$ .

C.9 Remark. Pseudo-morphisms preserve finite products.

C.10 Theorem. (Non-strict one-sorted algebraic duality) The 2-category of

objects: one-sorted algebraic theories,

1-cells: pseudo-morphisms,

2-cells: natural transformations,

is dually biequivalent to the 2-category of

February 1, 2010 221

objects: pseudo-one-sorted algebraic categories,

1-cells: pseudo-concrete functors,

2-cells: natural transformations.

**Proof.** The proof is analogous to that of 11.38, just observe that from a pseudo-concrete functor

$$(G,\varphi)\colon (Alg \mathcal{T}_2, Alg \mathcal{T}_2) \to (Alg \mathcal{T}_1, Alg \mathcal{T}_1)$$

we get a natural isomorphism  $\psi: F_{T_1} \to F \cdot F_{T_2}$  between the left adjoints. The rest of the proof of 11.38 can now be repeated with no other changes.

**C.11 Remark.** In Appendix A we have obtained the duality between the category of one-sorted algebraic theories and the category of uniquely transportable one-sorted algebraic categories using finitary monads. We are going to derive such a duality from the biequivalence of Theorem C.10. In order to perform this we need several preliminary steps. We start by an observation explainin why when we restrict our attention to uniquely transportable one-sorted algebraic categories we do not need a non-strict version.

**C.12 Lemma.** Let  $(\mathcal{A}_1, U_1), (\mathcal{A}_2, U_2)$  be concrete categories over  $\mathcal{K}$ .

1. If  $(\mathcal{A}_2, U_2)$  is transportable, then for every pseudo-concrete functor

 $G\colon (\mathcal{A}_1, U_1) \to (\mathcal{A}_2, U_2)$ 

there exists a concrete functor  $H: (\mathcal{A}_1, U_1) \to (\mathcal{A}_2, U_2)$  naturally isomorphic to G.

2. If  $(A_1, U_1)$  and  $(A_2, U_2)$  are transportable, then they are pseudo-concretely equivalent if and only if they are concretely equivalent.

**Proof.** 1. Let  $\varphi: U_1 \to U_2 \cdot G$  be a natural isomorphism. For every object  $A \in \mathcal{A}_1$ , consider the isomorphism

$$\varphi_A \colon U_1 A \to U_2 G A$$
.

Since  $(\mathcal{A}_2, U_2)$  is transportable, there exists an object HA in  $\mathcal{A}_2$  and an isomorphism

$$\psi_A \colon HA \to GA$$

such that  $U_2\psi_A = \varphi_A$ . This gives a map on objects  $H: \mathcal{A}_1 \to \mathcal{A}_2$ . For  $f: A \to B$ in  $\mathcal{A}_1$ , put  $Hf = \psi_B^{-1} \cdot Gf \cdot \psi_A$ . In this way H is a functor such that  $U_2 \cdot H = U_1$ , and  $\psi: H \to G$  is a natural isomorphism. 2. follows immediately from 1.

**C.13 Corollary.** Every transportable pseudo-one-sorted algebraic category is one-sorted algebraic.

Recall from 11.35 the 2-categories  $Th^{1}$  of one-sorted algebraic theories, and  $ALG^1$  of one-sorted algebraic categories. In the remaining part of this appendix we consider  $Th^{1}$  and  $ALG^{1}$  as categories, that is, we forget the 2-cells. Explicitely:

#### C.14 Definition.

1. The category  $Th^{1}$  of one-sorted theories has

objects: one-sorted algebraic theories,

morphisms: morphisms of one-sorted algebraic theories.

2. The category  $ALG^1$  of one-sorted algebraic categories has

objects: one-sorted algebraic categories,

morphisms: concrete functors.

3. The category  $ALG_u^1$  is the full subcategory of  $ALG^1$  of all uniquely transportable one-sorted algebraic categories.

C.15 Lemma. The category  $Th^1$  (seen as a 2-category with only identity 2cells) is biequivalent to the 2-category  $PsTh^1$  having

objects: one-sorted algebraic theories  $(\mathcal{T}, T)$ ,

1-cells from  $(\mathcal{T}_1, \mathcal{T}_1)$  to  $(\mathcal{T}_2, \mathcal{T}_2)$ : pairs  $(M, \mu)$  with  $M : \mathcal{T}_1 \to \mathcal{T}_2$  a pseudomorphism of one-sorted theories and  $\mu \colon M \cdot T_1 \to T_2$  a natural isomorphism,

2-cells from  $(M, \mu)$  to  $(N, \nu)$ : natural transformations  $\alpha \colon M \to N$  which are coherent, i.e., such that  $\nu \cdot \alpha T_1 = \mu$ .

(1) Let us start by observing that the coherence condition  $\nu \cdot \alpha T_1 = \mu$ Proof. on a 2-cell  $\alpha$  of  $PsTh^1$  immediately implies that  $\alpha$  is invertible and that between two parallel 1-cells of  $PsTh^1$  there is at most one 2-cell. (2) The inclusion  $Th^1 \to PsTh^1$  is a biequivalence: since  $Th^1$  and  $PsTh^1$  have

the same objects, we have to prove that the induced functor

$$Th^{1}((\mathcal{T}_{1}, T_{1}), (\mathcal{T}_{2}, T_{2})) \to PsTh^{1}((\mathcal{T}_{1}, T_{1}), (\mathcal{T}_{2}, T_{2}))$$

is full and essentially surjective (it is certainly faithful because  $Th^1$  has only identity 2-cells).

(2a) Full: let  $M, N: (\mathcal{T}_1, \mathcal{T}_1) \to (\mathcal{T}_2, \mathcal{T}_2)$  be 1-cells in  $Th^1$  and  $\alpha: (M, =) \to (N, =)$  a 2-cell in  $PsTh^1$ . The coherence condition gives  $\alpha_n =$  id for every  $n \in \mathcal{N}$ , and then M = N by naturality of  $\alpha$ .

(2b) Essentially surjective: consider a 1-cell  $(M,\mu): (\mathcal{T}_1,\mathcal{T}_1) \to (\mathcal{T}_2,\mathcal{T}_2)$  in  $PsTh^{1}$ . We define a functor

$$N: \mathcal{T}_1 \to \mathcal{T}_2, \ N(f: x \to y) = \mu_y \cdot Mf \cdot \mu_x^{-1}: x \to y.$$

It is easy to check that  $N \cdot T_1 = T_2$  and that  $\mu \colon (M, \mu) \to (N, =)$  is a 2-cell in  $PsTh^{1}$ .

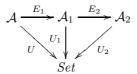

**C.16 Lemma.** The category  $ALG_u^1$  (seen as a 2-category with only identity 2-cells) is biequivalent to the 2-category  $PsALG^1$  having

objects: pseudo-one-sorted algebraic categories  $(\mathcal{A}, U)$ ,

1-cells from  $(\mathcal{A}_1, U_1)$  to  $(\mathcal{A}_2, U_2)$ : pseudo-concrete with  $G: \mathcal{A}_1 \to \mathcal{A}_2$  a functor and  $\varphi: U_1 \to U_2 \cdot G$  a natural isomorphism,

2-cells from  $(G, \varphi)$  to  $(H, \psi)$ : natural transformations  $\alpha \colon G \to H$  which are coherent, i.e., such that  $U_2 \alpha \cdot \varphi = \psi$ .

**Proof.** (1) Let us start by observing that, since  $U_2$  is conservative, the coherence condition  $U_2 \alpha \cdot \varphi = \psi$  implies that  $\alpha$  is invertible and, since  $U_2$  is faithful, it implies that between two parallel 1-cells of  $PsALG^1$  there is at most one 2-cell. (2) The inclusion  $ALG_u^1 \rightarrow PsALG^1$  is essentially surjective (in the sense of the 2-category  $PsALG^1$ ): let  $(\mathcal{A}, U)$  be an object in  $PsALG^1$ . We are going to construct the diagram

where  $E_1$  and  $E_2$  are pseudo-concrete equivalences,  $(\mathcal{A}_1, U_1)$  is transportable, and  $(\mathcal{A}_2, U_2)$  is uniquely transportable. Therefore,  $(\mathcal{A}_2, U_2)$  is a uniquely transportable pseudo-one-sorted algebraic category. By Corollary C.13 we conclude that  $(\mathcal{A}_2, U_2)$  is an object of  $ALG_u^1$ .

(2a) Objects in  $\mathcal{A}_1$  are triples  $(A, \pi_{A,X} \colon UA \to X, X)$  with  $A \in \mathcal{A}, X$  a set and  $\pi_{A,X}$  an isomorphism. A morphism from  $(A, \pi_{A,X}, X)$  to  $(A', \pi_{A',X'}, X')$ is a pair of morphism  $a \colon A \to A', x \colon X \to X'$  such that  $x \cdot \pi_{A,X} = \pi_{A',X'} \cdot Ua$ . Clearly the forgetful functor

$$U_1: \mathcal{A}_1 \to Set, \ U_1(A, \pi_{A,X}, X) = X$$

is transportable. Moreover, we have an equivalence

$$E_1: \mathcal{A} \to \mathcal{A}_1$$
,  $E_1 \mathcal{A} = (\mathcal{A}, \mathrm{id}_{U\mathcal{A}}, U\mathcal{A})$ 

with quasi-inverse the forgetful functor

$$E'_1: \mathcal{A}_1 \to \mathcal{A}, \quad E'_1(A, \pi_{A,X}, X) = A$$

Note that  $E_1$  is a concrete functor, whereas  $E'_1$  is pseudo-concrete: a natural isomorphism  $\pi: U \cdot E'_1 \to U_1$  is given by

$$\pi_{(A,\pi_{A,X},X)} = \pi_{A,X} \,.$$

(2b) Consider any concrete category  $U_1: \mathcal{A}_1 \to Set$ . Objects of  $\mathcal{A}_2$  are equivalence classes of objects of  $\mathcal{A}_1$ , with X equivalent to X' if there exists a  $U_1$ -identity  $i: X \to X'$ , that is, an isomorphism i such that  $U_1 i = \operatorname{id}_{U_1 X}$ . We denote by

February 1, 2010

224

[X] the equivalence classe of X. The hom-set  $\mathcal{A}_2([X][Z])$  is the quotient of the disjoint union of the  $\mathcal{A}_1(X', Z')$  for  $X' \in [X], Z' \in [Z]$ , with  $f: X \to Z$  equivalent to  $f': X' \to Z'$  if there exist  $U_1$ -identites  $i: X \to X'$  and  $j: Z \to Z'$  and  $U_1f = U_1f'$ . The composition of  $[f]: [X] \to [Z]$  and  $[g]: [Z] \to [W]$  is  $[gjf]: [X] \to [W]$ , where  $j: Z \to Z'$  is any  $U_1$ -identity. The functors  $E_2$  and  $U_2$  are defined by

$$E_2: \mathcal{A}_1 \to \mathcal{A}_2, \ E_2(f: X \to Z) = [f]: [X] \to [Z],$$

$$U_2: \mathcal{A}_2 \to Set, \ U_2([f]: [X] \to [Z]) = Ff: FX \to FZ.$$

Clearly,  $U_2 \cdot E_2 = U_1$  and  $E_2$  is full and surjective on objects, so that it is an equivalence (because  $U_1$  is faithful). Finally, it is easy to check that  $U_2$  is amnestic if  $U_1$  is conservative, and that  $U_2$  is transportable if  $U_1$  is transportable. (3) The induced functor

$$ALG^{1}_{u}((\mathcal{A}_{1}, U_{1}), (\mathcal{A}_{2}, U_{2})) \rightarrow PsALG^{1}((\mathcal{A}_{1}, U_{1}), (\mathcal{A}_{2}, U_{2}))$$

is an equivalence:

(3a) Full: let  $G, H: (\mathcal{A}_1, U_1) \to (\mathcal{A}_2, U_2)$  be 1-cells in  $ALG_u^1$  and  $\alpha: (G, =) \to (H, =)$  a 2-cell in  $PsALG^1$ . The coherence condition gives  $U_2(\alpha_A) = \text{id}$  for every  $A \in \mathcal{A}$ . Since  $U_2$  is amnestic,  $\alpha_A$  is the identity.

(3b) Faithful: obvious because  $ALG^1$  has only identity 2-cells.

(3c) Essentially surjective: let  $(\mathcal{A}_1, U_1)$ ,  $(\mathcal{A}_2, U_2)$  be objects in  $ALG_u^1$  and  $(G, \varphi): (\mathcal{A}_1, U_1) \to (\mathcal{A}_2, U_2)$  a 1-cell in  $PsALG^1$ . As in the proof of C.12 we get a concrete functor  $H: (\mathcal{A}_1, U_1) \to (\mathcal{A}_2, U_2)$  and a natural isomorphism  $\psi: H \to G$ . To end the proof observe that  $\psi: (H, =) \to (G, \varphi)$  is a 2-cell in  $PsALG^1$ . Indeed, the condition  $U_2(\psi_A) = \varphi_A$  is precisely the coherence condition on  $\psi$ .

Recall the 2-functor  $Alg^1: (Th^1)^{op} \to ALG^1$  from 11.37. There is an obvious version of this 2-functor in the present context: all we need to observe is that given a coherent natural transformation  $\alpha$  in  $PsTh^1$ , then  $Alg\alpha$  is also coherent. By a slight abuse of notation we denote this 2-functor by  $Alg^1$  again:

C.17 Notation. We denote by

$$Alg^1: (PsTh^1)^{op} \to PsALG^1$$

the 2-functor assigning to every one-sorted theory  $(\mathcal{T}, T)$  the one-sorted algebraic category  $(Alg\mathcal{T}, AlgT)$ , to every 1-cell  $(M, \mu): (\mathcal{T}_1, \mathcal{T}_1) \to (\mathcal{T}_2, \mathcal{T}_2)$  the 1-cell  $(AlgM, Alg\mu^{-1})$ , and to every 2-cell  $\alpha: (M, \mu) \to (N, \nu)$  the 2-cell  $Alg\alpha$  whose component at a  $\mathcal{T}_2$ -algebra A is  $A \cdot \alpha: A \cdot M \to A \cdot N$ .

**C.18 Theorem.** (One-sorted algebraic duality) The category  $ALG_u^1$  of uniquely transportable one-sorted algebraic categories is equivalent to the dual of the category  $Th^1$  of one-sorted algebraic theories. In fact, the 2-functor

$$Alg^1: (PsTh^1)^{op} \to PsALG^1$$

is a biequivalence.

**Proof.** (1) The 2-functor  $Alg^1$  is well-defined by 11.8. (2) The 2-functor  $Alg^1$  is essentially surjective (in the sense of the 2-category  $PsALG^1$ ): following C.6, for every object  $(\mathcal{A}, U)$  of  $PsALG^1$  there exists a pseudo-concrete equivalence  $E: \mathcal{A} \to Alg \mathcal{T}$  with natural isomorphism

$$\varphi \colon AlgT \cdot E \to U$$

Recall from 0.3 that it is possible to choose a quasi-inverse  $E' \colon Alg \mathcal{T} \to \mathcal{A}$  and natural isomorphisms

$$\eta \colon \operatorname{Id}_{Alg \mathcal{T}} \to E \cdot E' \text{ and } \varepsilon \colon E' \cdot E \to \operatorname{Id}_{\mathcal{A}}$$

such that

$$E\varepsilon \cdot \eta E = E$$
 and  $\varepsilon E' \cdot E' \eta = E'$ 

We get a natural isomorphism

$$\psi = \varphi^{-1} E' \cdot Alg T \eta \colon Alg T \to U \cdot E' \,.$$

It follows that

$$\eta \colon (\mathrm{Id}_{Alg\,\mathcal{T}},=) \to (E \cdot E', \varphi E' \cdot \psi) \text{ and } \varepsilon \colon (E' \cdot E, \psi E \cdot \varphi) \to (\mathrm{Id}_{\mathcal{A}},=)$$

are 2-cells in  $PsALG^1$ . Indeed, the coherence condition on  $\eta$  is just the definition of  $\psi$ , and the coherence condition on  $\varepsilon$  follows from the equation  $E\varepsilon \cdot \eta E = E$ :

$$U\varepsilon\cdot\psi E\cdot\varphi = U\varepsilon\cdot\varphi^{-1}E'E\cdot AlgT\eta E\cdot\varphi = \varphi^{-1}\cdot AlgTE\varepsilon\cdot AlgT\eta E\cdot\varphi = \varphi^{-1}\cdot\varphi = U.$$

We conclude that  $(\mathcal{A}, U)$  and  $(Alg \mathcal{T}, Alg \mathcal{T})$  are equivalent objects in  $PsALG^1$ . (3) We will prove that for two one-sorted algebraic theories  $(\mathcal{T}_1, \mathcal{T}_1)$  and  $(\mathcal{T}_2, \mathcal{T}_2)$ the functor

$$PsTh^{1}((\mathcal{T}_{1},T_{1}),(\mathcal{T}_{2},T_{2})) \xrightarrow{Alg^{1}(\mathcal{T}_{1},\mathcal{T}_{1}),(\mathcal{T}_{2},T_{2})} PsALG^{1}((Alg\mathcal{T}_{2},Alg\mathcal{T}_{2}),(Alg\mathcal{T}_{1},Alg\mathcal{T}_{1}))$$

is an equivalence of categories.

(3a) Full and faithful: the proof as in Theorem 9.15, indeed  $\alpha \colon M \to N$  is coherent iff  $Alg \alpha \colon Alg M \to Alg N$  is coherent.

(3b) Essentially surjective: we follow the proof of 11.38. Let

$$(G,\varphi)\colon (Alg\,\mathcal{T}_2,Alg\,\mathcal{T}_2)\to (Alg\,\mathcal{T}_1,Alg\,\mathcal{T}_1)$$

be a 1-cell in  $PsALG^1$  and  $\psi \colon F_{T_2} \to F \cdot F_{T_1}$  the induced natural isomorphism on the adjoint functors. As in 11.38 we get a 1-cell

$$(M,=)\colon (\mathcal{T}_1,\mathcal{T}_1)\to (\mathcal{T}_2,\mathcal{T}_2)$$

in  $PsTh^{1}$  and we have to construct a 2-cell

$$\alpha \colon (Alg M, =) \to (G, \varphi)$$

in  $PsALG^1$ . Since  $AlgT_1 \cdot AlgM = AlgT_2$ , there exists a natural isomorphism  $i: F_{T_2} \to M^* \cdot F_{T_1}$ . Let

$$\psi_{|}: Y_{\mathcal{T}_{2}} \cdot M^{op} \to F \cdot Y_{\mathcal{T}_{1}}, \ i_{|}: Y_{\mathcal{T}_{2}} \cdot M^{op} \to M^{*} \cdot Y_{\mathcal{T}_{1}}$$

be the restrictions of  $\psi$  and i to  $\mathcal{T}_1$ . By 9.3, there exists a natural isomorphism  $\alpha^* \colon M^* \to F$ . Moreover,  $\alpha^*$  is unique with the condition  $\alpha^* Y_{\mathcal{T}_1} \cdot i_{|} = \psi_{|}$  (apply 4.11 to  $Y_{\mathcal{T}_1}$ ). Since  $F_{\mathcal{T}_2}$  and  $F \cdot F_{\mathcal{T}_1}$  preserve colimits, the previous equation gives  $\alpha^* F_{\mathcal{T}_1} \cdot i = \psi$  (apply 4.11 to  $Y_{\mathcal{N}}$ ). Passing to the right adjoints, we get a natural isomorphism  $\alpha \colon Alg M \to G$  such that  $(Alg \mathcal{T}_1)\alpha = \varphi$ , as required.  $\Box$
