# The Eigenvalue Distribution of 

# Random Matrices with Distortions 

Kevin Hunt

April 2019

## 1. Introduction

Random matrix theory is often concerned with describing the limiting eigenvalue distribution of random matrix ensembles. For example, Wigner's semicircle law shows that the empirical distribution of eigenvalues for real symmetric matrices with independent, mean zero, and variance one random entries scaled by $\sqrt{N}$ converges weakly in probability to the semicircle law [1]. It has been shown that the eigenvalue distributions of Toeplitz and Hankel matrices with independent, mean zero, and variance one entries each converge almost surely to a unique distribution [3].

A natural next question is to study what happens to the limiting eigenvalue distribution when making slight changes to some of the entries of a matrix ensemble. The limiting distributions of matrix ensembles have been studied when the $(i, j)$ and $(j, i)$ entries are randomly multiplied by $\epsilon_{i, j}=\epsilon_{j, i} \in\{-1,1\}$ where $\mathbb{P}\left(\epsilon_{i, j}=1\right)=p$. For $p=1 / 2$, the limiting eigenvalue distribution is the semicircle law when each random variable occurs $O(N)$ times in each row; this result holds for Toeplitz and circulant matrix ensembles [1]. The k-checkerboard matrix has been defined and studied, where each entry on the kth diagonal is equal to some constant $w$, and all other entries are independent, mean zero, variance one random variables. It has been shown that the eigenvalue distribution of this random matrix ensemble converges weakly in probability to the semicircle law. This can be thought of as changing the kth diagonals of a Wigner matrix to $w$.

In this thesis we study what happens when some entries of a random matrix ensemble are changed to zero. We consider adding these zero distortions randomly, and we consider when the distortions are added in a specific non-random way. In general, we show that under certain conditions the limiting distributions of the eigenvalues are not changed, either in a random or structured way, if "not too many" of the entries in the matrix are changed to zero.

### 1.1. Background

Here we introduce some definitions and notations that will be useful for our results.
Definition 1.1: Given a real symmetric $N x N$ random matrix $A_{N}$, we can list its real eigenvalues as $\lambda_{i}^{N}$ with $\lambda_{1}^{N} \leq \lambda_{2}^{N} \leq \cdots \leq \lambda_{N}^{N}$. The empirical distribution of the eigenvalues of $A_{N}$ is then defined as the random probability measure on $\mathbb{R}$ given by

$$
L_{N}:=\frac{1}{N} \sum_{i=1}^{N} \delta_{\lambda_{i}^{N}} .
$$

Definition 1.2: $L_{N}$ converges weakly in probability to some distribution $\boldsymbol{\alpha}$ if for all functions $f \in C_{b}(\mathbb{R})$, the set of all bounded continuous functions on $\mathbb{R}$, and for all $\epsilon>0$

$$
\lim _{N \rightarrow \infty} \mathbb{P}\left(\left|\left\langle f, L_{N}\right\rangle-\langle f, \boldsymbol{\alpha}\rangle\right|>\epsilon\right)=0
$$

Definition 1.3: Given two real $N x N$ matrices $A_{N}$ and $B_{N}$, the Hadamard product matrix $H_{N}=A_{N} \circ B_{N}$ is the $N x N$ matrix whose $(i, j)^{t h}$ entry $H_{N}(i, j)=A_{N}(i, j) \circ B_{N}(i, j)$.

Definition 1.4: Given a real symmetric $N x N$ random matrix $A_{N}$ and a symmetric $N x N$ matrix $1_{N}$ whose entries are either 1 or 0 , we can list the real eigenvalues of $1_{N} \circ A_{N}$ as $\xi_{i}^{N}$ with $\xi_{1}^{N} \leq \xi_{2}^{N} \leq \cdots \leq \xi_{N}^{N}$. The empirical distribution of these eigenvalues is then defined as the random probability measure on $\mathbb{R}$ give by

$$
D_{N}:=\frac{1}{N} \sum_{i=1} \delta_{\xi_{i}^{N}} .
$$

Definition 1.5: Consider two sequences of i.i.d. random variables $\left\{Z_{i, j}\right\}_{1 \leq i<j}$ and $\left\{Y_{i}\right\}_{1 \leq i}$ with mean zero and variance one that satisfy $\max \left\{E Z_{1,2}^{k}, E Y_{1}^{k}\right\}<\infty$ for all $k \in \mathbb{N}$. Then a Wigner matrix is a real symmetric random matrix with entries

$$
X_{N}(i, j)=X_{N}(j, i)=\left\{\begin{array}{l}
\frac{Z_{i, j}}{\sqrt{N}} \text { if } i \neq j \\
\frac{Y_{i}}{\sqrt{N}} \text { if } i=j
\end{array} .\right.
$$

Definition 1.6: The semicircle law scaled by $p$ is the distribution with density

$$
\boldsymbol{\sigma}_{\boldsymbol{p}}(x):=\frac{1}{2 p \pi} \sqrt{4 p-x^{2}} \cdot 1_{|x|<2 \sqrt{p}} .
$$

Wigner's Semicircle Law: The empirical distribution of the eigenvalues of the Wigner matrix ensemble $\left\{X_{N}\right\}$ converges weakly in probability to $\boldsymbol{\sigma}_{\boldsymbol{1}}$.

Definition 1.6: For an NxN non-random symmetric matrix $1_{N}$ whose entries are zero or one, we define

$$
\theta(N):=\sum_{i, j=1}^{N} 1_{N}(i, j), \quad \text { and } \quad \theta_{i}(N):=\sum_{j=1}^{N} 1_{N}(i, j)=\sum_{j=1}^{N} 1_{N}(j, i)
$$

### 1.2 Results

The first result involves an ensemble of random matrices $\left\{A_{N}\right\}$ whose entries all have non-negative moments. That is, $E A_{N}(i, j)^{k} \geq 0$ for all $i, j, k, N \in \mathbb{N}$. The distorting matrix $1_{N}$ will have its entries be Bernoulli random variables.

Theorem 1.1: Suppose $\left\{A_{N}\right\}$ is any ensemble of symmetric random matrices whose entries have non-negative moments. Suppose $\left\{1_{N}\right\}$ is an ensemble of symmetric random matrices composed of Bernoulli random variables with parameter $p(N) \in(0,1]$ and $\lim _{N \rightarrow \infty} p(N)=1$. If the empirical distribution of the eigenvalues of $A_{N}$ converges weakly in probability to some distribution $\boldsymbol{\alpha}$ which has bounded support, then the empirical distribution of the eigenvalues of $1_{N}{ }^{\circ} A_{N}$ converges to $\boldsymbol{\alpha}$ as well.

If $\lim _{N \rightarrow \infty} p(N)=p \in(0,1]$, then we can say something about the limiting distribution of the eigenvalues if we know the structure of the ensemble $A_{N}$. For example, suppose $\left\{A_{N}\right\}$ is an ensemble of Wigner matrices defined earlier, then $1_{N} \circ A_{N}$ has independent entries with mean zero and variance $p$. Then the matrix ensemble $B_{N}$ with each entry multiplied by the constant $\frac{1}{\sqrt{p}}$

$$
B_{N}=\frac{1}{\sqrt{p}} \cdot 1_{N} \circ A_{N}
$$

will have mean zero, variance one, independent entries. Because $B_{N}$ satisfies the conditions for Wigner's semicircle law, then the empirical distribution of the eigenvalues of $B_{N}$ converges to $\boldsymbol{\sigma}_{\mathbf{1}}$. This tells us that the eigenvalues of $1_{N} \circ A_{N}$ are just the eigenvalues of $B_{N}$ multiplied by $\sqrt{p}$, and thus, the limiting distribution of the eigenvalues of $1_{N} \circ A_{N}$ is $\sigma_{\sqrt{p}}$. Also, Wigner matrices can have negative moments beyond the second moment, so this result did not follow from Theorem 1.1 for $p=1$.

We now consider distortions added in a non-random way, specifically for the Wigner random matrix ensemble.

Theorem 1.2: Suppose $\left\{X_{N}\right\}$ is an ensemble of Wigner random matrices, and $\left\{1_{N}\right\}$ are nonrandom matrices with entries equal to zero or one, and for all $j, \theta_{j}\left(1_{N}\right)=p N$ with $p \in(0,1]$. Then the empirical distribution of the eigenvalues of $1_{N}{ }^{\circ} X_{N}$ converges to $\sigma_{\sqrt{p}}$.

Theorem 1.3: Suppose $\left\{X_{N}\right\}$ is an ensemble of Wigner random matrices, and $\left\{1_{N}\right\}$ are nonrandom symmetric matrices with entries equal to zero or one, and

$$
\lim _{N \rightarrow \infty} \frac{\theta\left(1_{N}\right)}{N^{2}}=0 .
$$

Then the empirical distribution of the eigenvalues of $1_{N}{ }^{\circ} X_{N}$ converges to $\boldsymbol{\sigma}_{\mathbf{1}}$.
Theorems 1.2 and 1.3 only cover a limited number of possible $1_{N}$ matrices. We have yet to find a general formula for the limiting eigenvalue distribution of $1_{N} \circ X_{N}$, but we do have equations for the first eight moments, and a process for finding all higher moments. We will discuss these topics in section 3.

## 2. Method of Moments

All our proofs will be done by the Method of Moments as described in [1], which is described in Theorem 2.1. The proof requires two conditions, we will proof in each of the previously discussed cases.

Theorem 2.1: Let $\left\{A_{N}\right\}$ be an ensemble of $N x N$ random matrices with empirical distribution of the eigenvalues $L_{N}$, and let $\boldsymbol{\alpha}$ be some distribution with bounded support [ $-M, M$ ]. Suppose that
(i) For all $k \in \mathbb{N}$,

$$
\lim _{N \rightarrow \infty} E\left\langle x^{k}, L_{N}\right\rangle=E\left\langle x^{k}, \boldsymbol{\alpha}\right\rangle
$$

(ii) For all $k \in \mathbb{N}$ and $\epsilon>0$,

$$
\lim _{N \rightarrow 0} \mathbb{P}\left(\left|\left\langle x^{k}, L_{N}\right\rangle-E\left\langle x^{k}, L_{N}\right\rangle\right|>\epsilon\right)=0 .
$$

Then the empirical measure of the eigenvalues $L_{N}$ converges weakly in probability, to the distribution $\boldsymbol{\alpha}$.

Assume that $L_{N}$ and $\boldsymbol{\alpha}$ satisfy conditions (i) and (ii). We need to show that for all continuous bounded functions $f$ and for all $\delta>0$ :

$$
\lim _{N \rightarrow \infty} \mathbb{P}\left(\left|\left\langle f, L_{N}\right\rangle-\langle f, \boldsymbol{\alpha}\rangle\right|>\delta\right)=0 .
$$

For such an $f$ by the Weirstrass Approximation Theorem, we can find a polynomial $Q_{\delta}(x):=\sum_{i=1}^{B} b_{i} x^{i}$ that satisfies:

$$
\sup _{x:|x| \leq R}\left|Q_{\delta}(x)-f(x)\right| \leq \frac{\delta}{8}
$$

where $R=(2 M)^{2}$. Note,

$$
\begin{gathered}
\mathbb{P}\left(\left|\left\langle f, L_{N}\right\rangle-\langle f, \boldsymbol{\alpha}\rangle\right|>\delta\right) \leq \\
\left.\mathbb{P}\left(\left|\left\langle f, L_{N}\right\rangle-\langle f, \boldsymbol{\alpha}\rangle\right| \cdot 1_{|x| \leq B}\right\rangle \delta\right)+\mathbb{P}\left(\left|\left\langle f, L_{N}\right\rangle-\langle f, \boldsymbol{\alpha}\rangle\right| \cdot 1_{|x|>B}>\delta\right) \leq \\
\mathbb{P}\left(\left|\left\langle f, L_{N}\right\rangle-E\left\langle f, L_{N}\right\rangle\right| \cdot 1_{|x| \leq B}>\frac{\delta}{2}\right)+\mathbb{P}\left(\left|E\left\langle f, L_{N}\right\rangle-\langle f, \boldsymbol{\alpha}\rangle\right| \cdot 1_{|x| \leq B}>\frac{\delta}{2}\right) \\
+\mathbb{P}\left(\left|\left\langle f, L_{N}\right\rangle\right| \cdot 1_{|x|>B}>\frac{\delta}{2}\right)+\mathbb{P}\left(|\langle f, \boldsymbol{\alpha}\rangle| \cdot 1_{|x|>B}>\frac{\delta}{2}\right)=: P_{1}+P_{2}+P_{3}+P_{4} .
\end{gathered}
$$

First, $P_{4}=0$ because $\boldsymbol{\alpha}$ is only supported on $[-M, M]$, but $B=2 M$.
By definition of $Q_{\delta}$,

$$
P_{1}=\mathbb{P}\left(\left|\left\langle f, L_{N}\right\rangle-E\left\langle f, L_{N}\right\rangle\right| \cdot 1_{|x| \leq B}>\frac{\delta}{2}\right) \leq \mathbb{P}\left(\left|\left\langle Q_{\delta}, L_{N}\right\rangle-E\left\langle Q_{\delta}, L_{N}\right\rangle\right|>\frac{\delta}{4}\right) \rightarrow 0
$$

by Lemma 2.2. Similarly,

$$
P_{2}=\mathbb{P}\left(\left|E\left\langle Q_{\delta}, L_{N}\right\rangle-\langle f, \alpha\rangle\right| \cdot 1_{|x| \leq B}>\frac{\delta}{2}\right) \leq \mathbb{P}\left(\left|E\left\langle Q_{\delta}, L_{N}\right\rangle-\left\langle Q_{\delta}, \alpha\right\rangle\right|>\frac{\delta}{4}\right) \rightarrow 0
$$

by Lemma 2.1.
Finally, by Chebyshev's inequality for all $\epsilon>0$ :

$$
\left.\left.\mathbb{P}\left(\left.\langle | x\right|^{k} 1_{|x|>B}, L_{N}\right\rangle>\epsilon\right) \leq\left.\frac{1}{\epsilon} E\langle | x\right|^{k} 1_{|x|>B}, L_{N}\right\rangle \leq \frac{\left.\left.E\langle | x\right|^{2 k}, L_{N}\right\rangle}{\epsilon B^{k}}
$$

Then by Lemma 2.1,

$$
\left.\limsup _{N \rightarrow \infty} \mathbb{P}\left(\left.\langle | x\right|^{k} 1_{|x|>B}, L_{N}\right\rangle>\epsilon\right) \leq \frac{m_{2 k}}{\epsilon B^{k}} \leq \frac{M^{2 k}}{\epsilon(2 M)^{2 k}} .
$$

The left-hand side of the above expression is increasing in $k$, but the right-hand side is decreasing in $k$, so

$$
\left.\limsup _{N \rightarrow \infty} \mathbb{P}\left(\left.\langle | x\right|^{k} 1_{|x|>B}, L_{N}\right\rangle>\epsilon\right)=0
$$

This implies that $P_{3} \rightarrow 0$ as $N \rightarrow \infty$ which completes the proof of Theorem 2.3.
[There is an upward pointing arrow here in your previous comments, but I don't know what that meant.]

### 2.1. Proof of Theorem 1.1

Here we consider an ensemble of real symmetric random matrices $A_{N}$ whose empirical distribution of eigenvalues $L_{N}$ converges weakly in probability to some distribution $\boldsymbol{\alpha}$ with compact support. The matrices $A_{N}$ also have entries with nonnegative moments, that is $E A_{N}^{k}(i, j) \geq 0 \forall i, j, k, N \in \mathbb{N}$. These matrices are then distorted by multiplying $1_{N} \circ A_{N}$, where $1_{N}$ is a symmetric random matrix composed of Bernoulli random variables with parameter $p(N) \rightarrow 1$ as $N \rightarrow \infty$. The empirical distribution of the eigenvalues of $1_{N} \circ A_{N}$ is $D_{N}$ defined earlier.
Proof of Condition (i): By the independence of entries in $1_{N}$ and $A_{N}$ :

$$
\begin{gathered}
E\left\langle x^{k}, D_{N}\right\rangle=\frac{1}{N} \operatorname{tr}\left(1_{N} \circ A_{N}\right)^{k}=\frac{1}{N} \sum_{i_{1}, i_{2}, \ldots, i_{k}=1}^{N} E 1_{N}\left(i_{1}, i_{2}\right) A_{N}\left(i_{1}, i_{2}\right) \ldots 1_{N}\left(i_{k}, i_{1}\right) A_{N}\left(i_{k}, i_{1}\right) \\
=\frac{1}{N} \sum_{i_{1}, i_{2}, \ldots, i_{k}=1}^{N} E\left[1_{N}\left(i_{1}, i_{2}\right) \ldots 1_{N}\left(i_{k}, i_{1}\right)\right] \cdot E\left[A_{N}\left(i_{1}, i_{2}\right) \ldots A_{N}\left(i_{k}, i_{1}\right)\right] .
\end{gathered}
$$

Remember that every moment of the Bernoulli random variable is equal to its parameter $p(N) \leq 1$. The $E\left[1_{N}\left(i_{1}, i_{2}\right) \ldots 1_{N}\left(i_{k}, i_{1}\right)\right]$ term is the expectation of at most $k$ independent Bernoulli random variables, which happens when none of the indices generate entries that are the same, and at least one Bernoulli random variable, which happens when the indices all generate the same entry. Therefore,

$$
p(N)^{k} \leq E\left[1_{N}\left(i_{1}, i_{2}\right) \ldots 1_{N}\left(i_{k}, i_{1}\right)\right] \leq p(N) .
$$

Since the moments of the entries in $A_{N}$ are non-negative, we can create bounds on $E\left\langle x^{k}, D_{N}\right\rangle$ as follows:

$$
\begin{aligned}
& p(N)^{k} \frac{1}{N} \sum_{i_{1}, i_{2}, \ldots, i_{k}=1}^{N} E A_{N}\left(i_{1}, i_{2}\right) \ldots A_{N}\left(i_{k}, i_{1}\right) \\
& \leq E\left\langle x^{k}, D_{N}\right\rangle \leq \\
& p(N) \frac{1}{N} \sum_{i_{1}, i_{2}, \ldots, i_{k}=1}^{N} E A_{N}\left(i_{1}, i_{2}\right) \ldots A_{N}\left(i_{k}, i_{1}\right)
\end{aligned}
$$

The summations in the upper and lower bounds are the kth moments of the eigenvalue distribution of $A_{N}$, so

$$
p(N)^{k} \cdot E\left\langle x^{k}, L_{N}\right\rangle \leq E\left\langle x^{k}, D_{N}\right\rangle \leq p(N) \cdot E\left\langle x^{k}, L_{N}\right\rangle
$$

By assumption, $p(N) \rightarrow 1$ and $E\left\langle x^{k}, L_{N}\right\rangle \rightarrow E\left\langle x^{k}, \alpha\right\rangle$. Then the above inequalities show that

$$
\lim _{N \rightarrow \infty} E\left\langle x^{k}, D_{N}\right\rangle=E\left\langle x^{k}, \boldsymbol{\alpha}\right\rangle .
$$

Proof of Condition (ii): By Markov's inequality,

$$
\mathbb{P}\left(\left|\left\langle x^{k}, D_{N}\right\rangle-E\left\langle x^{k}, D_{N}\right\rangle\right|>\epsilon\right) \leq \frac{1}{\epsilon} E\left|\left\langle x^{k}, D_{N}\right\rangle-E\left\langle x^{k}, D_{N}\right\rangle\right|
$$

$$
\begin{aligned}
\leq \frac{1}{\epsilon}\left(E\left|\left\langle x^{k}, D_{N}\right\rangle-\left\langle x^{k}, L_{N}\right\rangle\right|+\right. & \left.E\left|\left\langle x^{k}, L_{N}\right\rangle-E\left\langle x^{k}, \boldsymbol{\alpha}\right\rangle\right|+E\left|E\left\langle x^{k}, \boldsymbol{\alpha}\right\rangle-E\left\langle x^{k}, D_{N}\right\rangle\right|\right) \\
& =: \frac{1}{\epsilon}\left(T_{1}+T_{2}+T_{3}\right)
\end{aligned}
$$

First, $T_{2}$ goes to zero because $L_{N}$ converges weakly in probability to $\boldsymbol{\alpha}$. Also, $T_{3}$ goes to zero because $E\left[\left\langle x^{k}, D_{N}\right\rangle\right]$ converges to $E\left[\left\langle x^{k}, \boldsymbol{\alpha}\right\rangle\right]$. Finally,

$$
\begin{aligned}
T_{1}=\frac{1}{N} \operatorname{tr} A_{N}^{k}- & \operatorname{tr}\left(1_{N} \circ A_{N}\right)^{k} \\
& =\frac{1}{N} \sum_{i_{1}, \ldots i_{k}=1}^{N}\left(1-E 1_{N}\left(i_{1}, i_{2}\right) \ldots 1_{N}\left(i_{k}, i_{1}\right)\right) E A_{N}\left(i_{1}, i_{2}\right) \ldots A_{N}\left(i_{k}, i_{1}\right) .
\end{aligned}
$$

The $1-E 1_{N}\left(i_{1}, i_{2}\right) \ldots 1_{N}\left(i_{k}, i_{1}\right)$ term contains at most $k$ independent Bernoulli random variables, and at least one, so

$$
1-p(N) \leq 1-E 1_{N}\left(i_{1}, i_{2}\right) \ldots 1_{N}\left(i_{k}, i_{1}\right) \leq 1-p(N)^{k} .
$$

Therefore, $(1-p(N)) E\left[\left\langle x^{k}, L_{N}\right\rangle\right] \leq T_{1} \leq\left(1-p(N)^{k}\right) E\left[\left\langle x^{k}, L_{N}\right\rangle\right]$. Taking the limit as $N \rightarrow \infty$ in the above expression shows $T_{1} \rightarrow 0$. Therefore, $\lim _{N \rightarrow \infty} \mathbb{P}\left(\left|\left\langle x^{k}, D_{N}\right\rangle-E\left\langle x^{k}, D_{N}\right\rangle\right|>\epsilon\right)=0$.

Now that we have shown conditions (i) and (ii) to be true under the conditions of Theorem 1.1, we know that the theorem holds.

### 2.2. Proof of Theorem 1.2

Now we consider the ensemble of Wigner random matrices $X_{N}$ described in Definition 1.5 . The eigenvalue distribution of $X_{N}$ converges weakly in probability to the semicircle law $\sigma_{1}$ described before. A full proof of this can be found in [1], which shows Wigner's original argument. We consider Wigner matrices $X_{N}$ distorted by multiplying $1_{N}$ 。 $X_{N}$, where $1_{N}$ is symmetric and composed of entries equal to zero or one. Also, $\theta_{j}\left(1_{N}\right)=$ $p N$ for all $j$ with $p \in(0,1)$. With a slight change to the argument found in [1], we show the eigenvalue distribution of $1_{N} \circ X_{N}$ converges to the semicircle law scaled by $\sqrt{p}$, denoted by $\sigma_{\sqrt{p}}$.

First, we find the moments of $\sigma_{\sqrt{p}}$. Let $C_{n}$ denote the nth Catalan number for $n \in \mathbb{N}$, which is:

$$
C_{n}=\frac{1}{n+1}\binom{2 n}{n} .
$$

If $k$ is odd, then because $\boldsymbol{\sigma}_{\boldsymbol{p}}$ is an even function and $x^{k}$ is an odd function

$$
E\left\langle x^{k}, \boldsymbol{\sigma}_{\sqrt{p}}\right\rangle=\frac{1}{2 \sqrt{p} \pi} \int x^{k} \boldsymbol{\sigma}_{\sqrt{p}}(\boldsymbol{x}) 1_{|x| \leq p^{\frac{1}{4}}} d x=0 .
$$

For even moments,

$$
\begin{aligned}
E\left\langle x^{2 k}, \boldsymbol{\sigma}_{\sqrt{\boldsymbol{p}}}\right\rangle= & \frac{1}{2 \sqrt{p} \pi} \int x^{2 k} \boldsymbol{\sigma}_{\boldsymbol{p}}(\boldsymbol{x}) 1_{|x| \leq p^{\frac{1}{4}}} d x=\frac{2^{2 k+1} p^{k}}{\pi} \int \sin ^{2 k} \theta \cos ^{2} \theta d \theta \\
& =\frac{2^{2 k+1} p^{k}}{\pi} \int \sin ^{2 k} \theta d \theta-(2 k+1) E\left\langle x^{2 k}, \boldsymbol{\sigma}_{\sqrt{p}}\right\rangle .
\end{aligned}
$$

Therefore,

$$
E\left\langle x^{2 k}, \sigma_{\sqrt{p}}\right\rangle=\frac{2^{2 k+1} p^{k}}{\pi(2 k+2)} \int \sin ^{2 k} \theta d \theta=p^{k} \frac{4(2 k-1)}{2 k+2} m_{2 k-2},
$$

Using induction and starting with $E\left\langle x^{0}, \boldsymbol{\sigma}_{\sqrt{p}}\right\rangle=1$, we can see that $E\left\langle x^{2 k}, \sigma_{\sqrt{p}}\right\rangle=p^{k} C_{k}$.

Proof of Condition (i): Let $\widetilde{\mathrm{X}}_{N}(i, j)=1_{N}(i, j) \cdot X_{N}(i, j)$ and similarly for $\tilde{Y}_{i}$ and $\widetilde{Z}_{i, j}$. Then

$$
\mathrm{E}\left\langle x^{k}, D_{N}\right\rangle=\frac{1}{N} \operatorname{tr}\left(1_{N} \circ X_{N}\right)^{k}=\frac{1}{\mathrm{~N}} \sum_{i_{1}, \ldots, i_{k}=1} E \tilde{X}_{N}\left(i_{1}, i_{2}\right) \ldots \tilde{X}\left(i_{k}, i_{1}\right)=\frac{1}{\mathrm{~N}} \sum_{i} T_{i}^{N}
$$

where $\boldsymbol{i}=\left(i_{1}, i_{2}, \ldots i_{k}\right)$.
An $N$-word of length $m \geq 1$ is $w=a_{1} a_{2} . . a_{m}$ where $a_{j} \in\{1, \ldots, N\}$. The support of $w$ denoted $\operatorname{supp}(w)$ is the unique elements appearing in $w$, and the weight of $w$ denoted $\mathrm{wt}(w)=|\operatorname{supp}(w)|$. Each word $w$ generates an undirected graph $G_{w}$ with $m-1$ edges and $\mathrm{wt}(w)$ vertices. Denote the undirected edges of $G_{w}$ by $E_{w}=\left\{\left\{i_{s}, i_{s+1}\right\}: s=1,2, \ldots, m-1\right\}$, and the vertices of $G_{w}$ by $V_{w}=\operatorname{supp} w$. The self-edges of $w$ are $E_{w}^{s}=\left\{e \in E_{w}: e=\{b, b\}, b \in\right.$ $\operatorname{supp}(w)\}$, and the connecting edges of $w$ are $E_{w}^{c}=E_{w}-E_{w}^{s}$. The number of times the graph $G_{w}$ crosses edge $e$ is denoted by $N_{w}^{e}$. A word $w$ is closed if $a_{1}=a_{m}$.

With these definitions, we see that each $\boldsymbol{i}$ is a closed connected $N$-word of length $k+$ 1 where $w_{i}=i_{1} i_{2} \ldots i_{k} i_{1}$. Therefore,

$$
T_{i}^{N}=\frac{1}{N^{k / 2}} \prod_{e \in E_{w_{i}}^{c}} E \tilde{Z}_{1,2}^{N_{w_{i}}^{e}} \prod_{e \in E_{w_{i}}^{s}} E \tilde{Y}_{1,1}^{N_{w_{i}}^{e}} .
$$

If there is $e \in E_{w_{i}}$ with $N_{w_{i}}^{e}=1$, then $T_{i}=0$ because $E \tilde{Z}_{1,2}=E \tilde{Y}_{1,1}=0$. Thus, we only need to consider $\boldsymbol{i}$ where $N_{w_{i}}^{e} \geq 2$ for all $e \in E_{w_{i}}$. Because $w_{i}$ has $k$ edges and each vertex after the first accounts for two edges, $\mathrm{wt}\left(w_{i}\right) \leq k / 2+1$.

If there is a bijection from $w_{i}$ to $w_{j}$, these words are called equivalent and generate the same graph up to graph isomorphism, meaning that $T_{i}=T_{j}$. For an N -word $w_{i}$ with $\mathrm{wt}\left(w_{\boldsymbol{i}}\right)=u$, the number of words equivalent to $w_{\boldsymbol{i}}$ is given by $\psi_{N, u}$ where

$$
\begin{equation*}
N(p N-1) \ldots(p N-u+1) \leq \psi_{N, u} \leq(p N)^{\frac{k}{2}} \tag{2.2.1}
\end{equation*}
$$

Let $\mathbb{W}_{k, u}$ be the set of representatives for the equivalence classes of closed N -words $w_{i}$ of length $k+1$ and weight $u$. Then

$$
E\left\langle x^{k}, D_{N}\right\rangle=\sum_{u=1}^{\lfloor k / 2\rfloor+1} \frac{\psi_{N, u}}{N^{k / 2+1}} \sum_{w \in \mathbb{W}_{k, u}} \prod_{e \in E_{\mathbf{w}}^{c}} E \tilde{Z}_{1,2}^{N_{w}^{e}} \prod_{e \in E_{w}^{s}} E \tilde{Y}_{1,1}^{N_{w}^{e}}
$$

The moments of $Z_{1,2}$ and $Y_{1,1}$ are all finite by assumption. $\left|\mathbb{W}_{k, u}\right| \leq u^{k} \leq k^{k}$ because there are $u$ vertices for each of the $k$ edges to end at in the $N$-word of weight $u$ and length $k+1$. Also, $\psi_{N, u} \leq N^{u}$. From these inequalities if $k$ is odd, then $\lfloor k / 2\rfloor+1=k / 2-1 / 2$, so

$$
\lim _{N \rightarrow \infty} E\left\langle x^{k}, D_{N}\right\rangle=0
$$

For $k$ even, $\lfloor k / 2\rfloor+1=k / 2+1$, so

$$
\lim _{N \rightarrow \infty} E\left\langle x^{k}, D_{N}\right\rangle=p^{\frac{k}{2}} \sum_{w \in \mathbb{W}_{k, k / 2+1}} \prod_{e \in E_{\mathfrak{w}}^{c}} E \tilde{Z}_{1,2}^{N_{w}^{e}} \prod_{e \in E_{w}^{s}} E \tilde{Y}_{1,1}^{N_{w}^{e}} .
$$

Any $w \in \mathbb{W}_{k, k / 2+1}$ is connected and $\left|V_{w}\right|=k / 2+1$. This tells us that $\left|E_{w}\right| \geq k / 2$. Because $N_{e}^{w} \geq 2$ for all $e \in E_{w},\left|E_{w}\right| \leq k / 2$, which tells us that $\left|E_{w}\right|=k / 2$. This tells us that $\left|N_{e}^{w}\right|=$ 2 for all $e \in\left|V_{w}\right|$.

A tree is a connected graph with no cycles. Any graph $G$ with $\left|E_{G}\right|=\left|V_{G}\right|-1$ is a tree, so each $w \in \mathbb{W}_{k, k / 2+1}$ is a tree. Because these $w$ have no cycles, $E_{w}^{S}=\emptyset$. This tells us that for even $k$

$$
\lim _{N \rightarrow \infty} E\left\langle x^{k}, D_{N}\right\rangle=p^{\frac{k}{2}}\left|\mathbb{W}_{k, k / 2+1}\right| .
$$

A Bernoulli walk of length $\ell$ is an integer valued sequence $\left\{B_{n}\right\}_{n=1}^{\ell}$ with $\left|B_{i}-B_{i-1}\right|=1$. A Dyck path of length $\ell$ is a non-negative Bernoulli walk of length $\ell$ with $B_{1}=B_{\ell}=0$. To complete the proof and as shown in [1] on page 15, for $k$ even we construct a bijection between $\mathbb{W}_{k, k / 2+1}$ and the Dyck paths of length $k$. Also, shown in [1] on page 8 , there are $C_{\frac{k}{2}}$ Dyck paths of length $k$ for $k$ even. This completes the proof of condition (i)

Proof of Condition (ii): By Chebyshev's inequality,

$$
\mathbb{P}\left(\left|\left\langle x^{k}, D_{N}\right\rangle-E\left\langle x^{k}, D_{N}\right\rangle\right|>\epsilon\right) \leq \frac{1}{\epsilon^{2}}\left(E\left[\left\langle x^{k}, D_{N}\right\rangle^{2}\right]-E\left[\left\langle x^{k}, D_{N}\right\rangle\right]^{2}\right) .
$$

We will show that

$$
\lim _{N \rightarrow \infty} E\left(\left\langle x^{k}, D_{N}\right\rangle^{2}\right)-E\left(\left\langle x^{k}, D_{N}\right\rangle\right)^{2}=0 .
$$

Using the same definitions for $\boldsymbol{i}$ and $T_{\boldsymbol{i}}^{N}$ as in the proof of Lemma 2.1,

$$
E\left(\left\langle x^{k}, D_{N}\right\rangle^{2}\right)-E\left(\left\langle x^{k}, D_{N}\right\rangle\right)^{2}=\frac{1}{N^{2}} \sum_{i, i^{\prime}} E T_{i}^{N} T_{i^{\prime}}^{N}-E T_{\boldsymbol{i}}^{N} E T_{\boldsymbol{i}^{\prime}}^{N} .
$$

An N -sentence is a finite sequence of N -words $r=a_{1}, a_{s} \ldots, a_{n}$. The support of the sentence $\operatorname{supp} r=\cup_{j=1}^{n} \operatorname{supp}\left(a_{j}\right)$, and the weight $\operatorname{wt}(r)=|\operatorname{supp}(r)|$. Let each word $a_{i}=$ $b_{1}^{i} b_{2}^{i} \ldots b_{\ell\left(a_{i}\right)}^{i}$. Then the undirected graph generated by sentence $s G_{s}$ has vertices $V_{r}=$ $\operatorname{supp}(r)$ and edges $E_{r}=\left\{\left\{b_{k}^{i}, b_{k+1}^{i}\right\}: k=1,2, \ldots, \ell\left(a_{i}\right) ; i=1,2, \ldots, n\right\}$. The self edges of the graph generated by $r E_{r}^{s}=\left\{e \in E_{r}: e=\{u, u\}, u \in V_{r}\right\}$, and the connecting edges $E_{r}^{c}=E_{r}-$ $E_{r}^{s}$. Note that the graph need not be connected. Let $N_{r}^{e}$ be the number of times the graph $G_{r}$ crosses edge $e$.

With these definitions and notation, we denote by $r_{i, i}$ the two-word $N$-sentence $w_{i}, w_{i^{\prime}}$. Then

$$
\begin{aligned}
& E T_{i}^{N} T_{i^{\prime}}^{N}-E T_{i}^{N} T_{i^{\prime}}^{N} \\
&=\frac{1}{N^{k}}\left[\prod_{e \in E_{r_{i, i^{\prime}}^{c}}^{c}} E \tilde{Z}_{1,2}^{N_{r i, i}^{e}} \prod_{e \in E_{r_{i, i}}^{s}} E \tilde{Y}_{1,1}^{N_{i, i}} e^{e}\right. \\
&\left.-\prod_{e \in E_{w_{i}}^{c}} E \tilde{Z}_{1,2}^{N_{w_{i}}^{e}} \prod_{e \in E_{w_{i}}^{s}} E \tilde{Y}_{1,1}^{N_{w_{i}}^{e}} \prod_{e \in E_{w_{i^{\prime}}}^{c}} E \tilde{Z}_{1,2}^{N_{w_{i}}^{e}} \prod_{e \in E_{w_{i^{\prime}}}^{e}} E \tilde{Y}_{1,1}^{N_{w_{i^{\prime}}}^{e}}\right] .
\end{aligned}
$$

If $N_{r_{i, i}}^{e}=1$ for any $e \in E_{r_{i, i}}$, then $E T_{i}^{N} T_{i^{\prime}}^{N}-E T_{i}^{N} T_{i^{\prime}}^{N}=0$. If $E_{w_{i}} \cap E_{w_{i^{\prime}}}=\emptyset$, then $E T_{i}^{N} T_{i^{\prime}}^{N}-$ $E T_{\boldsymbol{i}}^{N} T_{\boldsymbol{i}^{\prime}}^{N}=0$. Then we only need to consider $r_{i, i^{\prime}}$ where $N_{r_{i, i^{\prime}}}^{e} \geq 2$ for all $e \in E_{r_{i, i^{\prime}}}$ and $E_{w_{i}} \cap E_{w_{i^{\prime}}} \neq \emptyset$.

Two sentences $r_{i, i^{\prime}}$ and $r_{j, j^{\prime}}$ are equivalent if there is a bijection from one to the other. Therefore, they generate the same graph, and

$$
E T_{\boldsymbol{j}}^{N} T_{\boldsymbol{j}^{\prime}}^{N}-E T_{\boldsymbol{j}}^{N} T_{\boldsymbol{j}^{\prime}}^{N}=E T_{\boldsymbol{j}}^{N} T_{\boldsymbol{j}^{\prime}}^{N}-E T_{\boldsymbol{j}}^{N} T_{\boldsymbol{j}^{\prime}}^{N}
$$

There are exactly $\psi_{N, u} \mathrm{~N}$-sentences equivalent to any given N -sentences of weight $u$. Let $\mathbb{W}_{k, u}^{2}$ be the set of representatives for the equivalence classes of N -sentences $r$ of weight
$u$ consisting of two closed N -words $w_{1}, w_{2}$ of length $k+1$ with $N_{r}^{e} \geq 2$ for all $e \in E_{r}$ and $E_{w_{1}} \cap E_{w_{2}} \neq \emptyset$. Then

$$
\begin{aligned}
E\left(\left\langle x^{k}, D_{N}\right\rangle^{2}\right)- & E\left(\left\langle x^{k}, D_{N}\right\rangle\right)^{2} \\
& =\sum_{u=1}^{2 k} \frac{\psi_{N, u}}{N^{k+2}} \sum_{r=\left(w_{1}, w_{2}\right) \in W_{k, u}}^{2}\left[\prod_{e \in E_{r_{i, i^{\prime}}}^{c}} E \tilde{Z}_{1,2}^{N_{r}^{e}} \prod_{e \in E_{r_{i, i^{\prime}}^{s}}^{s}} E \tilde{Y}_{1,1}^{N_{i}^{e}}\right. \\
& \left.-\prod_{e \in E_{w_{i}}^{c}} E \tilde{Z}_{1,2}^{N_{w_{i}}^{e}} \prod_{e \in E_{w_{i}}^{s}} E \tilde{Y}_{1,1}^{N_{w_{i}}^{e}} \prod_{e \in E_{w_{i^{\prime}}}^{e}} E \tilde{Z}_{1,2}^{N_{w_{i}}^{e}} \prod_{e \in E_{w_{i^{\prime}}}^{e}} E \tilde{Y}_{1,1}^{N_{w_{i^{\prime}}}^{e}}\right] .
\end{aligned}
$$

$\frac{\psi_{N, u}}{N^{k+2}} \leq N^{u-k-2}$. In the limit we only need to consider $u \geq k+2$. For each $r \in \mathbb{W}_{k, u}^{2}$ $E_{w_{1}} \cap E_{w_{2}} \neq \emptyset$, so the graph $G_{r}$ is a connected graph with $u$ vertices. The graph has at most $k$ edges since $N_{r}^{e} \geq 2$. It is clearly impossible to have a connect graph with $u \geq k+2$ vertices and at most $k$ edges, so $\mathbb{W}_{k, u}^{2}=\emptyset$. Thus,

$$
\lim _{n \rightarrow \infty} E\left(\left\langle x^{k}, D_{N}\right\rangle^{2}\right)-E\left(\left\langle x^{k}, D_{N}\right\rangle\right)^{2}=0
$$

### 2.3. Proof of Theorem 1.3

The proof of condition (ii) in for Theorem 1.2 in Section 2.2 still applies in this situation. For the proof of Lemma 1.2 , we know that if $k$ is odd, then

$$
\lim _{N \rightarrow \infty} E\left\langle x^{k}, D_{N}\right\rangle=0
$$

For $k$ even, we see that,

$$
\lim _{N \rightarrow \infty}\left|E\left\langle x^{k}, D_{N}\right\rangle-E\left\langle x^{k}, \boldsymbol{\sigma}_{\mathbf{1}}\right\rangle\right| \leq \lim _{N \rightarrow \infty}\left|E\left\langle x^{k}, L_{N}\right\rangle-E\left\langle x^{k}, D_{N}\right\rangle\right|+\lim _{N \rightarrow \infty}\left|E\left\langle x^{k}, L_{N}\right\rangle-E\left\langle x^{k}, \boldsymbol{\sigma}_{\mathbf{1}}\right\rangle\right| .
$$

The second term on the right-hand side goes to zero by Wigner's Semicircle Law. Then we only need to consider the first term.

$$
\left|E\left\langle x^{k}, L_{N}\right\rangle-E\left\langle x^{k}, D_{N}\right\rangle\right|=\left|\frac{1}{N^{k / 2+1}} \sum_{i_{1}, \ldots, i_{k}=1}\left[1-1_{N}\left(i_{1}, i_{2}\right) \ldots 1_{N}\left(i_{k}, i_{1}\right)\right] E X_{N}\left(i_{1}, i_{2}\right) \ldots X_{N}\left(i_{k}, i_{1}\right)\right|
$$

By the proof presented in Section 2.3, when ignoring the $\left[1-1_{N}\left(i_{1}, i_{2}\right) \ldots 1_{N}\left(i_{k}, i_{1}\right)\right]$ part of each term, we know that there are an order $C_{\frac{k}{2}} N^{k / 2+1}$ terms $E X_{N}\left(i_{1}, i_{2}\right) \ldots X_{N}\left(i_{k}, i_{1}\right)$ in the summation that survive when $N$ goes to $\infty$, and they are all equal to 1 . For each term we refer to the $X\left(i_{j}, i_{j+1}\right)$ as slot $j$, with $X\left(i_{k}, i_{1}\right)$ being slot k . Then entry $X_{N}(s, t)$ appears each slot $j$ an order of $C_{\frac{k}{2}} N^{k / 2-1}$ times. Then each entry appears in at most $k \cdot C_{\frac{k}{2}} \cdot N^{k / 2-1}$.

We see that $\left[1-1_{N}\left(i_{1}, i_{2}\right) \ldots 1_{N}\left(i_{k}, i_{1}\right)\right]=1$ whenever at least one of the $1_{N}\left(i_{j} i_{j+1}\right)$ is equal to zero. These are the distortions, and there are $\theta_{j}\left(1_{N}\right)$ of them. Because the $\theta_{j}\left(1_{N}\right)$ distortions appear in at most $k \cdot C_{\frac{k}{2}} \cdot N^{k / 2-1}$ terms,

$$
\left|E\left\langle x^{k}, L_{N}\right\rangle-E\left\langle x^{k}, D_{N}\right\rangle\right| \leq \theta\left(1_{N}\right) \cdot k \cdot C_{\frac{k}{2}} \cdot \frac{N^{k / 2-1}}{N^{k / 2+1}}=\frac{\theta_{j}\left(1_{N}\right)}{N^{2}} \rightarrow 0 .
$$

This completes the proof of conditions (i), so Theorem 1.3 holds.

## 3. The General Case of Theorem 1.2

Theorem 1.2 assumes that $\theta_{j}\left(1_{N}\right)=p N$ for all $j \in \mathbb{N}$. We have also studied when this is not the case, and $\theta_{j}\left(1_{N}\right)$ can be anything for each $j$. We are unable to prove any strong theorems in this case but are able to find some moments for the distribution of the eigenvalues. By the proof of Theorem 1.2, we still know that the odd moments are zero when taking the limit as $N$ goes to infinity. For the even moments we know that

$$
\begin{gathered}
\lim _{N \rightarrow \infty} E\left\langle x^{2}, D_{N}\right\rangle=\lim _{N \rightarrow \infty} \sum_{i_{1}, i_{2}=1}^{N} 1_{N}\left(i_{1}, i_{2}\right) . \\
\lim _{N \rightarrow \infty} E\left\langle x^{4}, D_{N}\right\rangle=\lim _{N \rightarrow \infty} 2 \sum_{i_{1}, i_{2}, i_{3}=1}^{N} 1_{N}\left(i_{1}, i_{2}\right) 1_{N}\left(i_{2}, i_{3}\right)=\sum_{j=1}^{N} \theta_{j}^{2} .
\end{gathered}
$$

$$
\begin{aligned}
\lim _{N \rightarrow \infty} E\left\langle x^{6}, D_{N}\right\rangle & =\lim _{N \rightarrow \infty}\left[2 \sum_{i_{1}, i_{2}, i_{3}=1}^{N} 1_{N}\left(i_{1}, i_{2}\right) 1_{N}\left(i_{2}, i_{3}\right) 1_{N}\left(i_{2}, i_{4}\right)\right. \\
& \left.+3 \sum_{i_{1}, i_{2}, i_{3}, i_{4}=1}^{N} 1_{N}\left(i_{1}, i_{2}\right) 1_{N}\left(i_{2}, i_{3}\right) 1_{N}\left(i_{3}, i_{4}\right)\right] \\
& =\lim _{N \rightarrow \infty}\left[2 \sum_{j=1}^{N} \theta_{j}^{2}+3 \sum_{i, j,=1}^{N} \theta_{i} 1_{N}(i, j) \theta_{j}\right] .
\end{aligned}
$$

We can find similar expressions for higher moments. We find these expressions by writing out all the possible graphs of closed words length $\frac{k}{2}+1$ where each edge in the graph are crossed twice, and then counting how many times each graph can be generated by a word. From the proof of Theorem 1.2, these are the only terms that are contribute to the sum in the limit. The graphs and counts for the for the moment equations shown above are listed on the next page.
