in which both squares are pullbacks, where $\overline{F}$ is a categorical equivalence; we wish to show that F is also a categorical equivalence. Using Proposition 4.1.3.2, we can factor $\overline{G}$ as a composition $\mathcal{C}_0 \xrightarrow{\iota_0} \mathcal{C}_0^+ \xrightarrow{V_0} \mathcal{C}$, where ι_0 is inner anodyne and V_0 is an inner fibration. In particular, $\mathcal{C}_0^+$ is an ∞ -category. Replacing $\mathcal{C}$ by $\mathcal{C}_0^+$ (and U by the projection map $\mathcal{C}_0^+ \times_{\mathcal{C}} \mathcal{E} \rightarrow \mathcal{C}_0^+$), we can assume that $\overline{G}$ is inner anodyne. In this case, Corollary 8.7.5.7 guarantees that G is a categorical equivalence of simplicial sets. It will therefore suffice to show that the composition $(G \circ F) : \mathcal{E}_1 \rightarrow \mathcal{E}$ is a categorical equivalence. Applying Proposition 4.1.3.2 again, we can factor $\overline{G} \circ \overline{F}$ as a composition $\mathcal{C}_1 \xrightarrow{\iota_1} \mathcal{C}_1^+ \xrightarrow{V_1} \mathcal{C}$, where ι_1 is inner anodyne and V_1 is an inner fibration. Applying Corollary 8.7.5.7 again, we conclude that the inclusion map $\mathcal{E}_1 \hookrightarrow \mathcal{C}_1^+ \times_{\mathcal{C}} \mathcal{E}$ is a categorical equivalence of simplicial sets. We are therefore reduced to showing that the projection map $\mathcal{C}_1^+ \times_{\mathcal{C}} \mathcal{E} \rightarrow \mathcal{E}$ is an equivalence of ∞ -categories. Note that $\overline{F}$, $\overline{G}$, and ι_1 are categorical equivalences of simplicial sets, so the inner fibration V_1 is an equivalence of ∞ -categories. The desired result now follows from Corollary 4.5.2.30 (since U is an isofibration). $\square$

Warning 8.7.5.18. In the formulation of Proposition 8.7.5.17, the assumption that U is an 05N4 isofibration cannot be omitted. For example, let $\mathcal{C}$ be a contractible Kan complex containing two vertices C_0 and C_1 , let $\mathcal{D}_1$ be an ∞ -category which is the idempotent-completion of a full subcategory $\mathcal{D}_0 \subseteq \mathcal{D}_1$, and let $\mathcal{E} \subseteq \mathcal{C} \times \mathcal{D}_1$ be the full subcategory spanned by those objects (C_i, D) where D is contained in $\mathcal{D}_i$. It follows from Example 8.7.5.10 that the projection map $U : \mathcal{E} \rightarrow \mathcal{C}$ is a flat inner fibration. However, if $\mathcal{D}_0$ is not idempotent-complete, then U is not an isofibration.

Corollary 8.7.5.19. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. Then U is 05N5 flat if and only if, for every n -simplex $\sigma : \Delta^n \rightarrow \mathcal{C}$, the projection map $\Delta^n \times_{\mathcal{C}} \mathcal{E} \rightarrow \Delta^n$ is exponentiable. Moreover, it suffices to verify this condition in the case $n = 2$.*

Proof. Combine Proposition 8.7.5.17 with Example 4.4.1.6. $\square$

We now show that the counterexample of Warning 8.7.5.18 is essentially the only way that a flat inner fibration can fail to be exponentiable.

05N6 **Lemma 8.7.5.20.** *Suppose we are given a commutative diagram of ∞ -categories*

$$\begin{array}{ccc} \mathcal{E} & \xrightarrow{F} & \mathcal{E}' \\ & \searrow U & \swarrow U' \\ & \mathcal{C}, & \end{array}$$

where U is a flat inner fibration, U' is an inner fibration, and F is an equivalence of ∞ -categories. Then:

- (1) *For every object $C \in \mathcal{C}$, the induced map of fibers $F_C : \mathcal{E}_C \rightarrow \mathcal{E}'_C$ is a Morita equivalence.*
- (2) *The inner fibration U' is flat.*

Note that, in the statement of Lemma 8.7.5.20, we do *not* assume that F is an equivalence of inner fibrations over $\mathcal{C}$ (otherwise, there would be nothing to prove).

Proof of Lemma 8.7.5.20. We will prove (1); assertion (2) then follows from Example 8.7.5.10. Using Corollary 4.5.2.24, we can factor the inclusion map $\{C\} \hookrightarrow \mathcal{C}$ as a composition $\{C\} \hookrightarrow \tilde{\mathcal{C}} \xrightarrow{V} \mathcal{C}$, where V is an isofibration and $\tilde{\mathcal{C}}$ is a contractible Kan complex. Set $\tilde{\mathcal{E}} = \tilde{\mathcal{C}} \times_{\mathcal{C}} \mathcal{E}$ and $\tilde{\mathcal{E}}' = \tilde{\mathcal{C}} \times_{\mathcal{C}} \mathcal{E}'$, so that we have a commutative diagram of ∞ -categories

$$\begin{array}{ccc} \mathcal{E}_C & \xrightarrow{F_C} & \mathcal{E}'_C \\ \downarrow & & \downarrow \\ \tilde{\mathcal{E}} & \xrightarrow{\tilde{F}} & \tilde{\mathcal{E}}'. \end{array}$$

It follows from Theorem 8.7.5.6 that the vertical maps are Morita equivalences, and from Corollary 4.5.2.30 that $\tilde{F}$ is an equivalence of ∞ -categories. Applying Remark 8.5.6.6, we conclude that F_C is a Morita equivalence. $\square$

05N7 **Warning 8.7.5.21.** Suppose we are given a commutative diagram of ∞ -categories

$$\begin{array}{ccc} \mathcal{E} & \xrightarrow{F} & \mathcal{E}' \\ & \searrow U & \swarrow U' \\ & \mathcal{C}, & \end{array}$$

where U and U' are inner fibrations and F is an equivalence of ∞ -categories (but not necessarily an equivalence of inner fibrations over $\mathcal{C}$). Lemma 8.7.5.20 asserts that if U is flat, then U' is also flat. Beware that the converse generally does not hold: if U' is flat, then U need not be flat. For example, suppose that U' is an isomorphism and that $F : \mathcal{E} \hookrightarrow \mathcal{E}'$ is an isomorphism from $\mathcal{E}$ to a full subcategory of $\mathcal{E}'$. If F is essentially surjective, then it is an equivalence of ∞ -categories. In this case, the inner fibration $U = U' \circ F$ is flat if and only if F is an isomorphism.

Proposition 8.7.5.22. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a flat inner fibration of ∞ -categories. Then U 05N8 factors as a composition $\mathcal{E} \xrightarrow{F} \mathcal{E}' \xrightarrow{U'} \mathcal{C}$, where F is an equivalence of ∞ -categories and U' is a flat isofibration. Moreover, for each object $C \in \mathcal{C}$, the induced map $F_C : \mathcal{E}_C \rightarrow \mathcal{E}'_C$ is a Morita equivalence.*

Proof. Combine Corollary 4.5.2.24 with Lemma 8.7.5.20. □

Corollary 8.7.5.23. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a flat inner fibration of ∞ -categories. Assume that, 05N9 for each vertex $C \in \mathcal{C}$, the ∞ -category $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is idempotent-complete. Then U is an isofibration. In particular, U is exponentiable.*

Proof. Using Proposition 8.7.5.22, we can factor U as a composition $\mathcal{E} \xrightarrow{F} \mathcal{E}' \xrightarrow{U'} \mathcal{C}$, where F is an equivalence of ∞ -categories and U' is an isofibration. For each object $C \in \mathcal{C}$, Lemma 8.7.5.20 guarantees that the induced map $F_C : \mathcal{E}_C \rightarrow \mathcal{E}'_C$ is a Morita equivalence; in particular, every object of $\mathcal{E}'_C$ is a retract of $F(X)$, for some object $X \in \mathcal{E}_C$ (see Proposition 8.5.6.11). Since $\mathcal{E}_C$ is idempotent-complete, it follows that F_C is an equivalence of ∞ -categories. Applying Corollary 5.1.7.10, we conclude that F is an equivalence of inner fibrations over $\mathcal{C}$, so that U is also an isofibration (Proposition 5.1.7.14). □

We now extend some of the preceding results to the case of inner fibrations between simplicial sets.

Proposition 8.7.5.24. *Let $\mathcal{C}$ be a simplicial set, let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a simplicial subset which 05NA contains every vertex of $\mathcal{C}$, and let $U_0 : \mathcal{E}_0 \rightarrow \mathcal{C}_0$ be a flat inner fibration. If the inclusion map $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ is a categorical equivalence, then there exists a pullback diagram*

$$\begin{array}{ccc} \mathcal{E}_0 & \longrightarrow & \mathcal{E} \\ \downarrow U_0 & & \downarrow U \\ \mathcal{C}_0 & \longrightarrow & \mathcal{C}, \end{array}$$

where U is a flat inner fibration.

Proof. Choose an uncountable regular cardinal κ for which the inner fibration U_0 is essentially κ -small. Using Theorem 8.7.4.1, we can choose a commutative diagram

$$\begin{array}{ccc} \mathcal{E}_0 & \xrightarrow{H_0} & \widehat{\mathcal{E}}_0 \\ & \searrow U_0 & \swarrow \widehat{U}_0 \\ & \mathcal{C} & \end{array}$$

which exhibits $\widehat{\mathcal{E}}_0$ as a fiberwise κ -cocompletion of $\mathcal{E}_0$. Let $\mathcal{E}'_0$ be the full simplicial subset of $\widehat{\mathcal{E}}_0$ spanned by those vertices which belong to the image of H_0 . It follows from Remark 8.7.1.8 that H_0 induces an equivalence $\mathcal{E}_0 \rightarrow \mathcal{E}'_0$ of inner fibrations over $\mathcal{C}_0$. Using Lemma 5.6.7.1 (and Remark 8.7.5.3), we can replace $\mathcal{E}_0$ by $\mathcal{E}'_0$ and thereby reduce to the case where H_0 is an isomorphism from $\mathcal{E}_0$ onto a full simplicial subset of $\widehat{\mathcal{E}}_0$.

Since U_0 is flat, the morphism $\widehat{U}_0$ is a cartesian fibration (Proposition 8.7.5.9). Using Proposition 5.6.7.2, we can choose a pullback diagram

$$\begin{array}{ccc} \widehat{\mathcal{E}}_0 & \xrightarrow{\quad} & \widehat{\mathcal{E}} \\ \downarrow \widehat{U}_0 & & \downarrow \widehat{U} \\ \mathcal{C}_0 & \xrightarrow{\quad \iota \quad} & \mathcal{C} \end{array}$$

where $\widehat{U}$ is a cartesian fibration. Let $\mathrm{Tr}_{\widehat{\mathcal{E}}/\mathcal{C}} : \mathrm{h}\mathcal{C}^{\mathrm{op}} \rightarrow \mathrm{h}\mathcal{Q}\mathcal{C}$ be the homotopy transport representation of $\widehat{U}$. Since ι induces an isomorphism of homotopy categories $\mathrm{h}\mathcal{C}_0 \xrightarrow{\sim} \mathrm{h}\mathcal{C}$, Proposition 8.7.1.12 guarantees that the functor $\mathrm{Tr}_{\widehat{\mathcal{E}}/\mathcal{C}}$ carries each object of $\mathrm{h}\mathcal{C}$ to a κ -cocomplete ∞ -category and each morphism of $\mathrm{h}\mathcal{C}$ to a functor which preserves κ -small colimits.

Let $\mathcal{E} \subseteq \widehat{\mathcal{E}}$ be the full simplicial subset spanned by those vertices which belong to the image of $\mathcal{E}_0$, and set $U = \widehat{U}|_{\mathcal{E}}$. Applying the criterion of Proposition 8.7.1.12, we see that the diagram

$$\begin{array}{ccc} \mathcal{E} & \xrightarrow{\quad} & \widehat{\mathcal{E}} \\ & \searrow U & \swarrow \widehat{U} \\ & \mathcal{C} & \end{array}$$

exhibits $\widehat{\mathcal{E}}$ as a fiberwise κ -cocompletion of $\mathcal{E}$. Since $\widehat{U}$ is a cartesian fibration, Proposition 8.7.5.9 guarantees that the inner fibration U is flat. By construction, the isomorphism $\widehat{\mathcal{E}}_0 \xrightarrow{\sim} \mathcal{C}_0 \times_{\mathcal{C}} \widehat{\mathcal{E}}$ restricts to an isomorphism of $\mathcal{E}_0$ with the fiber product $\mathcal{C}_0 \times_{\mathcal{C}} \mathcal{E}$. $\square$

Exercise 8.7.5.25. In the special case $\mathcal{C} = \Delta^2$ and $\mathcal{C}_0 = \Lambda_1^2$, Proposition 8.7.5.24 reduces 05NB to the assertion that every inner fibration $U_0 : \mathcal{E}_0 \rightarrow \Lambda_1^2$ fits into a pullback diagram

$$\begin{array}{ccc} \mathcal{E}_0 & \xrightarrow{F} & \mathcal{E} \\ \downarrow U_0 & & \downarrow U \\ \Lambda_1^2 & \xrightarrow{\quad} & \Delta^2, \end{array}$$

where $\mathcal{E}$ is an ∞ -category and F is a categorical equivalence of simplicial sets (see Corollary 8.7.5.16). Use the small object argument to give a more direct proof of this statement.

Corollary 8.7.5.26. *Let $U_0 : \mathcal{E}_0 \rightarrow \mathcal{C}_0$ be a flat inner fibration of simplicial sets. Then 05NC there exists a pullback diagram*

$$\begin{array}{ccc} \mathcal{E}_0 & \xrightarrow{\quad} & \mathcal{E} \\ \downarrow U_0 & & \downarrow U \\ \mathcal{C}_0 & \xrightarrow{\iota} & \mathcal{C}, \end{array}$$

where U is a flat inner fibration of ∞ -categories. Moreover, we may assume that ι is inner anodyne.

Corollary 8.7.5.27. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a flat inner fibration of simplicial sets. Assume that, 05ND for each vertex $C \in \mathcal{C}$, the ∞ -category $\mathcal{E}_C$ is idempotent-complete. Then U is an isofibration.*

Proof. Combine Corollaries 8.7.5.26 and 8.7.5.23. □

Corollary 8.7.5.28. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a flat inner fibration of simplicial sets and suppose 05NE we are given a digram*

$$\begin{array}{ccc} \mathcal{E} & \xrightarrow{H} & \widehat{\mathcal{E}} \\ & \searrow U & \swarrow \widehat{U} \\ & \mathcal{C} & \end{array}$$

which exhibits $\widehat{\mathcal{E}}$ as a fiberwise idempotent-completion of $\mathcal{E}$. Then $\widehat{U}$ is a flat isofibration.

Proof. It follows from Example 8.7.5.10 that $\widehat{U}$ is a flat inner fibration. Since the fibers of $\widehat{U}$ are idempotent-complete, it is an isofibration (Corollary 8.7.5.27). □

05NF **Proposition 8.7.5.29.** *Let $U_0 : \mathcal{E}_0 \rightarrow \mathcal{C}_0$ be a flat isofibration of simplicial sets. Then there exists a pullback diagram*

$$\begin{array}{ccc} \mathcal{E}_0 & \longrightarrow & \mathcal{E} \\ \downarrow U_0 & & \downarrow U \\ \mathcal{C}_0 & \xrightarrow{\iota} & \mathcal{C}, \end{array}$$

where U is a flat isofibration of ∞ -categories. Moreover, we may assume that ι is inner anodyne.

Proof. Using Corollary 8.7.5.26, we can choose an inner anodyne map $\iota : \mathcal{C}_0 \hookrightarrow \mathcal{C}$ and a pullback diagram

$$\begin{array}{ccc} \mathcal{E}_0 & \longrightarrow & \mathcal{E}' \\ \downarrow U_0 & & \downarrow U' \\ \mathcal{C}_0 & \xrightarrow{\iota} & \mathcal{C}, \end{array}$$

where U' is a flat isofibration. Using Proposition 8.7.5.22, we can factor U' as a composition $\mathcal{E}' \xrightarrow{F} \mathcal{E}'' \xrightarrow{U''} \mathcal{C}$, where F is an equivalence of ∞ -categories and U'' is a flat isofibration. Set $\mathcal{E}_0'' = \mathcal{C}_0 \times_{\mathcal{C}} \mathcal{E}''$, so that we have a commutative diagram

$$\begin{array}{ccc} \mathcal{E}_0 & \longrightarrow & \mathcal{E}' \\ \downarrow F_0 & & \downarrow F \\ \mathcal{E}_0'' & \longrightarrow & \mathcal{E}'' . \end{array}$$

Since U' and U'' are flat, Proposition 8.7.5.6 guarantees that the horizontal maps are categorical equivalences. Since F is an equivalence of ∞ -categories, it follows that F_0 is a categorical equivalence of simplicial sets (Remark 4.5.3.5), and therefore an equivalence of isofibrations over $\mathcal{C}_0$ (Proposition 5.1.7.5). Applying Lemma 5.6.7.1, we conclude that there exists a commutative diagram

$$\begin{array}{ccccc} \mathcal{E}_0 & \longrightarrow & \mathcal{E} & \xrightarrow{G} & \mathcal{E}'' \\ \downarrow & & \downarrow U & & \downarrow U'' \\ \mathcal{C}_0 & \xrightarrow{\iota} & \mathcal{C} & \xrightarrow{\text{id}} & \mathcal{C}, \end{array}$$

where the left square is a pullback, the upper horizontal composition is F_0 , and G is an equivalence of inner fibrations over $\mathcal{C}$. Since U'' is a flat isofibration, it follows that U is also a flat isofibration (Remark 8.7.5.3 and Proposition 5.1.7.14). $\square$

Corollary 8.7.5.30. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a flat isofibration of simplicial sets. Then U is 05NG exponentiable.*

Proof. By virtue of Proposition 8.7.5.29, we may assume that $\mathcal{C}$ is an ∞ -category. In this case, the result follows from Proposition 8.7.5.17. $\square$

8.7.6 Flatness and Morphism Spaces

Let $\mathcal{E}$ be an ∞ -category. For each morphism $f : X \rightarrow Z$ of $\mathcal{E}$, we let $\mathcal{E}_{X/|Z}$ denote the 05NH ∞ -category whose objects are diagrams of the form

$$\begin{array}{ccc} & Y & \\ & \nearrow & \searrow \\ X & \xrightarrow{f} & Z \end{array}$$

(see Notation 4.6.6.1). Our goal in this section is to prove the following:

Theorem 8.7.6.1. *Let $U : \mathcal{E} \rightarrow \Delta^2$ be a functor of ∞ -categories. Then U is flat if and only 05NJ if, for every morphism $f : X \rightarrow Z$ in $\mathcal{E}$ satisfying $U(X) = 0$ and $U(Z) = 2$, the ∞ -category $\{1\} \times_{\Delta^2} \mathcal{E}_{X/|Z}$ is weakly contractible.*

Stated more informally, Theorem 8.7.6.1 asserts that a functor $U : \mathcal{E} \rightarrow \Delta^2$ is flat if every morphism from an object $X \in \mathcal{E}_0$ to an object $Z \in \mathcal{E}_2$ admits a factorization through an object $Y \in \mathcal{E}_1$, which is unique up to (weakly) contractible choice. To carry out the proof, it will be useful to work with another formulation of this condition.

Lemma 8.7.6.2. *Let κ be an uncountable regular cardinal, let $\mathcal{E}$ be an ∞ -category which is 05NK essentially κ -small, let X be an object of $\mathcal{E}$, and let $h_X : \mathcal{E} \rightarrow \mathcal{S}_{<\kappa}$ be a functor corepresented by X . Let $U : \mathcal{E} \rightarrow \Delta^2$ be an inner fibration of ∞ -categories, let $\mathcal{E}_{\geq 1}$ be the full subcategory of $\mathcal{E}$ spanned by those objects E satisfying $U(E) \geq 1$, and let $\mathcal{E}_1$ denote the full subcategory spanned by those objects satisfying $U(E) = 1$. If U is flat, then the functor $h_X|_{\mathcal{E}_{\geq 1}}$ is left Kan extended from $\mathcal{E}_1$.*

Proof. Choose a functor $\mathcal{F}_{\geq 1} : \mathcal{E}_{\geq 1} \rightarrow \mathcal{S}$, and set $\mathcal{F}_1 = \mathcal{F}_{\geq 1}|_{\mathcal{E}_1}$. By virtue of Corollary 7.3.6.13, it will suffice to show that the restriction map

$$\theta : \mathrm{Hom}_{\mathrm{Fun}(\mathcal{E}_{\geq 1}, \mathcal{S}_{<\kappa})}(h_X|_{\mathcal{E}_{\geq 1}}, \mathcal{F}_{\geq 1}) \rightarrow \mathrm{Hom}_{\mathrm{Fun}(\mathcal{E}_1, \mathcal{S}_{<\kappa})}(h_X|_{\mathcal{E}_1}, \mathcal{F}_1)$$

is a homotopy equivalence of Kan complexes. Let $\mathcal{E}_{\leq 1}$ be the full subcategory of $\mathcal{E}$ spanned by those objects E satisfying $U(E) \leq 1$, and choose a regular cardinal λ of exponential cofinality $\geq \kappa$. Then the ∞ -category $\mathcal{S}_{<\lambda}$ is κ -complete (Example 7.6.6.11). Since $\mathcal{E}_{\leq 1}$ is essentially κ -small, the functor $\mathcal{F}_1$ admits a right Kan extension $\mathcal{F}_{\leq 1} : \mathcal{E}_{\leq 1} \rightarrow \mathcal{S}_{<\lambda}$. Our assumption that U is flat guarantees that the restriction functor

$$T : \mathrm{Fun}(\mathcal{E}, \mathcal{S}_{<\lambda}) \rightarrow \mathrm{Fun}(\mathcal{E}_{\leq 1}, \mathcal{S}_{<\lambda}) \times_{\mathrm{Fun}(\mathcal{E}_1, \mathcal{S}_{<\lambda})} \mathrm{Fun}(\mathcal{E}_{\geq 1}, \mathcal{S}_{<\lambda})$$

is a trivial Kan fibration, so that we can choose a functor $\mathcal{F} : \mathcal{E} \rightarrow \mathcal{S}_{<\lambda}$ satisfying $\mathcal{F}|_{\mathcal{E}_{\leq 1}} = \mathcal{F}_{\leq 1}$ and $\mathcal{F}|_{\mathcal{E}_{\geq 1}} = \mathcal{F}_{\geq 1}$. Since T is a trivial Kan fibration, the diagram of Kan complexes

$$\begin{array}{ccc} \mathrm{Hom}_{\mathrm{Fun}(\mathcal{E}, \mathcal{S}_{<\lambda})}(h_X, \mathcal{F}) & \xrightarrow{\theta'} & \mathrm{Hom}_{\mathrm{Fun}(\mathcal{E}_{\leq 1}, \mathcal{S}_{<\lambda})}(h_X|_{\mathcal{E}_{\leq 1}}, \mathcal{F}_{\leq 1}) \\ \downarrow & & \downarrow \\ \mathrm{Hom}_{\mathrm{Fun}(\mathcal{E}_{\geq 1}, \mathcal{S}_{<\lambda})}(h_X|_{\mathcal{E}_{\geq 1}}, \mathcal{F}_{\geq 1}) & \xrightarrow{\theta} & \mathrm{Hom}_{\mathrm{Fun}(\mathcal{E}_1, \mathcal{S}_{<\lambda})}(h_X|_{\mathcal{E}_1}, \mathcal{F}_1). \end{array}$$

Our assumption that $\mathcal{F}_{\leq 1}$ is right Kan extended from $\mathcal{F}_1$ guarantees that the right vertical map is a homotopy equivalence (Corollary 7.3.6.13). Consequently, to show that θ is a homotopy equivalence, it will suffice to show that θ' is a homotopy equivalence. This follows from the ∞ -categorical version of Yoneda's lemma (Proposition 8.3.1.3): the source and target of θ' can both be identified with the Kan complex $\mathcal{F}(X)$. $\square$

The converse of Lemma 8.7.6.2 is also true:

05NL Lemma 8.7.6.3. *Let $U : \mathcal{E} \rightarrow \Delta^2$ and κ be as in Lemma 8.7.6.2. Suppose that, for every object $X \in \mathcal{E}$ satisfying $U(X) = 0$, the functor $h_X|_{\mathcal{E}_{\geq 1}}$ is left Kan extended from $\mathcal{E}_1$. Then U is flat.*

Proof. Using Proposition 8.7.5.24 (or Exercise 8.7.5.25), we can choose a flat inner fibration $U' : \mathcal{E}' \rightarrow \Delta^2$ and an isomorphism $F_0 : \Lambda_1^2 \times_{\Delta^2} \mathcal{E}' \xrightarrow{\sim} \Lambda_1^2 \times_{\Delta^2} \mathcal{E}$ of simplicial sets over Λ_1^2 . Since the inclusion map $\Lambda_1^2 \times_{\Delta^2} \mathcal{E}' \hookrightarrow \mathcal{E}'$ is a categorical equivalence of simplicial sets, we can extend F_0 to a functor of ∞ -categories $F : \mathcal{E}' \rightarrow \mathcal{E}$ (which automatically satisfies $U \circ F = U'$). To prove that U is flat, it will suffice to show that F is an equivalence of inner fibrations over Δ^2 (Remark 8.7.5.3).

By construction, F is bijective on objects. By virtue of Corollary 5.1.7.10, we are reduced to showing that F is fully faithful: that is, for every pair of objects $X', Y' \in \mathcal{E}'$ having images $X = F(X')$ and $Y = F(Y')$, the morphism $\overline{F}$ induces a homotopy equivalence of Kan complexes $\mathrm{Hom}_{\mathcal{E}'}(X', Y') \rightarrow \mathrm{Hom}_{\mathcal{E}}(X, Y)$. We may assume that $U(X) = 0$ (otherwise, the

result follows immediately from the fact that F is an isomorphism). Choose an uncountable regular cardinal κ such that $\mathcal{E}$ and $\mathcal{E}'$ are essentially κ -small, let $h_X : \mathcal{E} \rightarrow \mathcal{S}_{<\kappa}$ be the functor represented by X , and define $h_{X'} : \mathcal{E}' \rightarrow \mathcal{S}_{<\kappa}$ similarly. The functor F then induces a natural transformation $\alpha : h_{X'} \rightarrow h_X \circ F$, and we wish to show that α is an isomorphism. Let $\mathcal{E}'_{\leq 1}$ denote the full subcategory of $\mathcal{E}'$ spanned by those objects Y satisfying $U(Y) \leq 1$, and define $\mathcal{E}'_1$ and $\mathcal{E}'_{\geq 1}$ similarly. Since F_0 is an isomorphism, the natural transformation α is an isomorphism when restricted to $\mathcal{E}'_{\leq 1}$. It will therefore suffice to show that α is also an isomorphism when restricted to $\mathcal{E}'_{\geq 1}$. Our assumption (and the fact that F_0 is an isomorphism) guarantees that $(h_X \circ F)|_{\mathcal{E}'_{\geq 1}}$ is left Kan extended from $\mathcal{E}'_1$. Since U' is flat, Lemma 8.7.6.2 guarantees that the functor $h_{X'}|_{\mathcal{E}'_{\geq 1}}$ is also left Kan extended from $\mathcal{E}'_1$. The desired result now follows from the fact that α is an isomorphism when restricted to $\mathcal{E}'_1$. $\square$

Proposition 8.7.6.4. *Let $U : \mathcal{E} \rightarrow \Delta^2$ be a functor of ∞ -categories. Then U is flat if and only if, for every object $X \in \mathcal{E}$ satisfying $U(X) = 0$, the inclusion functor* 05NM

$$\iota_X : \{1\} \times_{\Delta^2} \mathcal{E}_{X/} \hookrightarrow N_{\bullet}(\{1 < 2\}) \times_{\Delta^2} \mathcal{E}_{X/}$$

is left cofinal.

Proof. Choose an uncountable regular cardinal κ such that $\mathcal{E}$ is essentially κ -small. Using Lemmas 8.7.6.2 and 8.7.6.3, we see that U is flat if and only if, for every object $X \in \mathcal{E}$ satisfying $U(X) = 0$, the corepresentable functor $h_X : \mathcal{E} \rightarrow \mathcal{S}_{<\kappa}$ has the property that $h_X|_{\mathcal{E}_{\geq 1}}$ is left Kan extended from $\mathcal{E}_1$. Since h_X is a covariant transport representation for the left fibration $\mathcal{E}_{X/} \rightarrow \mathcal{E}$, this is equivalent to the requirement that ι_X is left cofinal (see Corollary 7.4.3.15). $\square$

Proof of Theorem 8.7.6.1. Let $U : \mathcal{E} \rightarrow \Delta^2$ be a functor of ∞ -categories and let X be an object of $\mathcal{E}$ satisfying $U(X) = 0$. By virtue of Proposition 8.7.6.4, it will suffice to show that the following conditions are equivalent:

- (1) The inclusion functor

$$\iota_X : \{1\} \times_{\Delta^2} \mathcal{E}_{X/} \hookrightarrow N_{\bullet}(\{1 < 2\}) \times_{\Delta^2} \mathcal{E}_{X/}$$

is left cofinal.

- (2) For every morphism $f : X \rightarrow Z$ of $\mathcal{E}$ where $U(Z) = 2$, the ∞ -category $\{1\} \times_{\Delta^2} \mathcal{E}_{X//Z}$ is weakly contractible.

This follows from the cofinality criterion of Theorem 7.2.3.1. $\square$

8.7.7 Fiberwise Cocompletion via the Yoneda Embedding

05NN Recall that, if $\mathcal{E}$ is an essentially small ∞ -category, then the contravariant Yoneda embedding $h^\bullet : \mathcal{E}^{\text{op}} \rightarrow \text{Fun}(\mathcal{E}, \mathcal{S})$ exhibits the ∞ -category $\text{Fun}(\mathcal{E}, \mathcal{S})$ as a cocompletion of $\mathcal{E}$ (Theorem 8.4.0.3). Our goal in this section is to prove a relative version of this statement.

05NP **Proposition 8.7.7.1.** *Let κ be an uncountable regular cardinal and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a flat inner fibration of simplicial sets which is essentially κ -small. Then:*

- (1) *The projection map $V : \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa}) \rightarrow \mathcal{C}$ is a cocartesian fibration of simplicial sets (see Construction 4.5.9.1).*
- (2) *Let $V^\dagger : \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger \rightarrow \mathcal{C}^{\text{op}}$ be a cartesian conjugate of V (Definition 8.6.1.1). Then $V^\dagger$ is a fiberwise κ -cocompletion of $U^{\text{op}} : \mathcal{E}^{\text{op}} \rightarrow \mathcal{C}^{\text{op}}$.*

The first assertion of Proposition 8.7.7.1 is a special case of the following:

05NQ **Lemma 8.7.7.2.** *Let κ be an uncountable regular cardinal, let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets which is essentially κ -small, and let $\mathcal{D}$ be an ∞ -category which is κ -cocomplete. Then the projection map $V : \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{D}) \rightarrow \mathcal{C}$ is a cocartesian fibration. Moreover, for every edge $e : C \rightarrow C'$ of $\mathcal{C}$, the covariant transport functor*

$$\text{Fun}(\mathcal{E}_C, \mathcal{D}) = \{C\} \times_{\mathcal{C}} \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{D}) \rightarrow \{C'\} \times_{\mathcal{C}} \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{D}) = \text{Fun}(\mathcal{E}_{C'}, \mathcal{D})$$

preserves κ -small colimits.

Proof. To show that V is a cocartesian fibration, we may assume without loss of generality that $\mathcal{C} = \Delta^n$ is a standard simplex (Proposition 5.1.4.8). In this case, U is exponentiable (Corollary 8.7.5.19), so the desired result follows from Variant 8.6.5.11. To prove the second assertion, we may assume that $\mathcal{C} = \Delta^1$ with $C = 0$ and $C' = 1$. In this case, $\mathcal{E}_C$ and $\mathcal{E}_{C'}$ are full subcategories of $\mathcal{E}$, and determine restriction functors $R : \text{Fun}(\mathcal{E}, \mathcal{D}) \rightarrow \text{Fun}(\mathcal{E}_C, \mathcal{D})$ and $R' : \text{Fun}(\mathcal{E}, \mathcal{D}) \rightarrow \text{Fun}(\mathcal{E}_{C'}, \mathcal{D})$. The covariant transport functor $e_!$ can then be identified with the composition $R' \circ R^L$, where R^L is left adjoint to R (given by left Kan extension along the inclusion $\mathcal{E}_C \hookrightarrow \mathcal{E}$). Since the functor R^L preserves all colimits (Corollary 7.1.4.23), we are reduced to showing that the functor R' preserves κ -small colimits, which follows from the criterion of Proposition 7.1.8.3. $\square$

To prove Proposition 8.7.7.1, we may assume without loss of generality that $U : \mathcal{E} \rightarrow \mathcal{C}$ is a flat inner fibration of ∞ -categories (Corollary 8.7.5.26). In this case, the results of §8.6.2 provide an explicit example of a cartesian dual of the inner fibration V .

05NR **Construction 8.7.7.3.** Let κ be an uncountable regular cardinal, let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a flat inner fibration of ∞ -categories which is essentially κ -small, and let $V : \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa}) \rightarrow \mathcal{C}$

be the cocartesian fibration of Lemma 8.7.7.2. We let $\text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger$ denote the full subcategory

$$\text{Fun}_{/\mathcal{C}}^{\text{CCart}}(\text{Tw}(\mathcal{C}) / \mathcal{C}^{\text{op}}, \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})) \subseteq \text{Fun}_{/\mathcal{C}}(\text{Tw}(\mathcal{C}) / \mathcal{C}^{\text{op}}, \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa}))$$

introduced in Construction 8.6.2.2, and let $V^\dagger : \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger \rightarrow \mathcal{C}^{\text{op}}$ denote the projection map. It follows from Proposition 8.6.2.3 that the evaluation map

$$\text{ev} : \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \rightarrow \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})$$

exhibits $V^\dagger$ as a cartesian conjugate of V .

By virtue of Lemma 8.7.7.2 (and Corollary 8.7.5.26), Proposition 8.7.7.1 is a consequence of the following more precise assertion:

Theorem 8.7.7.4. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a flat inner fibration of ∞ -categories, let κ be an $\aleph_1$ -regular uncountable regular cardinal for which U is essentially κ -small, and let*

$$H : \mathcal{E}^{\text{op}} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \times_{\mathcal{C}} \mathcal{E} \rightarrow \mathcal{S}_{<\kappa}$$

be a relative Hom-functor for U (see Definition 8.6.6.8), so that H is classified by a map

$$h : \mathcal{E}^{\text{op}} \rightarrow \text{Fun}(\text{Tw}(\mathcal{C}) \times_{\mathcal{C}} \mathcal{E} / \mathcal{C}^{\text{op}}, \mathcal{S}_{<\kappa}) \simeq \text{Fun}_{/\mathcal{C}}(\text{Tw}(\mathcal{C}) / \mathcal{C}^{\text{op}}, \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})).$$

Then:

- (1) *The functor h factors through the full subcategory*

$$\text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger \subseteq \text{Fun}_{/\mathcal{C}}(\text{Tw}(\mathcal{C}) / \mathcal{C}^{\text{op}}, \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa}))$$

of Construction 8.7.7.3.

- (2) *The diagram*

$$\begin{array}{ccc} \mathcal{E}^{\text{op}} & \xrightarrow{h} & \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger \\ & \searrow U^{\text{op}} & \swarrow V^\dagger \\ & \mathcal{C}^{\text{op}} & \end{array}$$

exhibits $\text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger$ as a fiberwise κ -cocompletion of $\mathcal{E}^{\text{op}}$.

We will carry out the proof of Theorem 8.7.7.4 in several steps.

05NT **Remark 8.7.7.5.** Let κ be an uncountable regular cardinal and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a flat inner fibration of ∞ -categories which is essentially κ -small. Suppose we are given a commutative diagram of simplicial sets

$$\begin{array}{ccc} \mathcal{D}^{\text{op}} & \xrightarrow{h} & \text{Fun}/_{\mathcal{C}}(\text{Tw}(\mathcal{C})/\mathcal{C}^{\text{op}}, \text{Fun}(\mathcal{E}/\mathcal{C}, \mathcal{S}_{<\kappa})) \\ & \searrow & \swarrow \\ & \mathcal{C}^{\text{op}}, & \end{array}$$

which we identify with a morphism $H : \mathcal{D}^{\text{op}} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \times_{\mathcal{C}} \mathcal{E} \rightarrow \mathcal{S}_{<\kappa}$. Using the criterion of Variant 8.6.5.11, we see that h factors through $\text{Fun}(\mathcal{E}/\mathcal{C}, \mathcal{S}_{<\kappa})^{\dagger}$ if and only if H satisfies the following condition:

(*) Let X be a vertex of $\mathcal{D}$ having image $C \in \mathcal{C}$, let e be an edge of $\{C\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C})$, and let H_e denote the composition

$$\Delta^1 \times_{\mathcal{C}} \mathcal{E} \xrightarrow{e \times \text{id}} \{C\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \times_{\mathcal{C}} \mathcal{E} \hookrightarrow \mathcal{D}^{\text{op}} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \times_{\mathcal{C}} \mathcal{E} \xrightarrow{H} \mathcal{S}_{<\kappa}.$$

Then the functor H_e is left Kan extended from $\{0\} \times_{\mathcal{C}} \mathcal{E}$.

Moreover, it suffice to verify condition (*) under the additional assumption that e belongs to the image of the equivalence $\mathcal{C}_{C/} \rightarrow \{C\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C})$ (see Proposition 8.1.2.9).

We now prove the first assertion of Theorem 8.7.7.4:

05NU **Lemma 8.7.7.6.** *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a flat inner fibration of ∞ -categories, let κ be an uncountable regular cardinal for which U is essentially κ -small, and let $H : \mathcal{E}^{\text{op}} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \times_{\mathcal{C}} \mathcal{E} \rightarrow \mathcal{S}_{<\kappa}$ be a relative Hom-functor for U . Then H is classified by a functor $h : \mathcal{E}^{\text{op}} \rightarrow \text{Fun}(\mathcal{E}/\mathcal{C}, \mathcal{S}_{<\kappa})^{\dagger}$.*

Proof. Fix an object $X \in \mathcal{E}$ having image $C = U(X)$ and an edge e of the ∞ -category $\mathcal{C}_{C/}$, which we identify with a 2-simplex σ :

$$\begin{array}{ccc} & C' & \\ & \nearrow & \searrow \\ C & \xrightarrow{\quad} & C'' \end{array}$$

of $\mathcal{C}$, and let $H_e : \mathbf{N}_{\bullet}(\{C' < C''\}) \times_{\mathcal{C}} \mathcal{E} \rightarrow \mathcal{S}_{<\kappa}$ be as in condition (*) of Remark 8.7.7.5; we wish to show that the functor F_e is left Kan extended from the subcategory $\{C'\} \times_{\mathcal{C}} \mathcal{E}$.

Without loss of generality, we may assume that $\mathcal{C} = \Delta^2$ and that σ is the identity morphism. In this case, we can identify F_e with the composition

$$N_\bullet(\{1 < 2\}) \times_{\Delta^2} \mathcal{E} \hookrightarrow \mathcal{E} \xrightarrow{\mathcal{F}} \mathcal{S}_{<\kappa},$$

where $\mathcal{F}$ is corepresented by the object $X \in \mathcal{E}$. Since U is flat, the desired result is a reformulation of Lemma 8.7.6.2. $\square$

We now prove a special case of Theorem 8.7.7.4.

Lemma 8.7.7.7. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a flat inner fibration of ∞ -categories, let κ be an uncountable regular cardinal for which U is essentially κ -small, and let* 05NV

$$H : \mathcal{E}^{\text{op}} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \times_{\mathcal{C}} \mathcal{E} \rightarrow \mathcal{S}_{<\kappa}$$

be a relative Hom-functor for U . Then the induced map $h : \mathcal{E}^{\text{op}} \rightarrow \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger$ exhibits $\text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})$ as a fiberwise κ -cocompletion of $\mathcal{E}^{\text{op}}$ (relative to $\mathcal{C}^{\text{op}}$).

Proof. Let us identify H with a functor $F : \mathcal{E}^{\text{op}} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \rightarrow \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})$. If X an object of $\mathcal{E}$ having image $C = U(X)$ and $u : C \rightarrow D$ is a morphism of $\mathcal{C}$, our assumption that U is a cocartesian fibration guarantees that we can lift u to a U -cocartesian morphism $\tilde{u} : X \rightarrow Y$ of $\mathcal{E}$. In this case, we can identify $F(X, u)$ with a functor $\mathcal{E}_D \rightarrow \mathcal{S}_{<\kappa}$ which is corepresented by the object Y . It follows that F factors through the full subcategory $\text{Fun}^{\text{corep}}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa}) \subseteq \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})$ of Construction 8.6.5.6. Unwinding the definitions, we have a commutative diagram

$$\begin{array}{ccc} \mathcal{E}^{\text{op}} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) & \xrightarrow{F} & \text{Fun}^{\text{corep}}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa}) \\ \downarrow h \times \text{id} & & \downarrow \\ \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) & \xrightarrow{\text{ev}} & \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa}). \end{array} \quad \begin{array}{l} \text{05NW} \\ (8.95) \end{array}$$

Let $V : \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa}) \rightarrow \mathcal{C}$ and $V^\dagger : \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger \rightarrow \mathcal{C}^{\text{op}}$ denote the projection maps, and set $V^{\text{corep}} = V|_{\text{Fun}^{\text{corep}}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})}$. Then the lower horizontal map exhibits $V^\dagger$ as a cartesian conjugate of V (Proposition 8.6.2.3), and the upper horizontal map exhibits U^{op} as a cartesian conjugate of V^{corep} (Theorem 8.6.6.15). Moreover, the inclusion map $\text{Fun}^{\text{corep}}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa}) \subseteq \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})$ exhibits $\text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})$ as a fiberwise κ -cocompletion of $\text{Fun}^{\text{corep}}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})$ (Example 8.7.2.4). Applying Proposition 8.7.3.3, we conclude that h exhibits $\text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger$ as a fiberwise κ -cocompletion of $\mathcal{E}^{\text{op}}$. $\square$

To prove Theorem 8.7.7.4, we need the following relative version of Yoneda's lemma:

05NX **Lemma 8.7.7.8.** *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a flat inner fibration of ∞ -categories which is essentially κ -small. Then the functor $h : \mathcal{E}^{\text{op}} \rightarrow \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger$ of Lemma 8.7.7.6 is fully faithful.*

Proof. Using Theorem 8.7.4.1, we can choose a diagram

$$\begin{array}{ccc} \mathcal{E}^{\text{op}} & \xrightarrow{F^{\text{op}}} & \widehat{\mathcal{E}}^{\text{op}} \\ & \searrow U^{\text{op}} & \swarrow \widehat{U}^{\text{op}} \\ & \mathcal{C}^{\text{op}} & \end{array}$$

which exhibits $\widehat{\mathcal{E}}^{\text{op}}$ as a fiberwise κ -cocompletion of $\mathcal{E}^{\text{op}}$. Since U is flat, the inner fibration U^{op} is also flat (Remark 8.7.5.5). Applying the criterion of Proposition 8.7.5.9, we see that $\widehat{U}^{\text{op}}$ is a cartesian fibration. Let λ be a regular cardinal of exponential cofinality $\geq \kappa$ such that $\widehat{U}$ is essentially λ -small. Let h^+ denote the composition of h with the inclusion functor

$$\begin{aligned} \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger &\hookrightarrow \text{Fun}_{/\mathcal{C}}(\text{Tw}(\mathcal{C}) / \mathcal{C}^{\text{op}}, \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})) \\ &\hookrightarrow \text{Fun}_{/\mathcal{C}}(\text{Tw}(\mathcal{C}) / \mathcal{C}^{\text{op}}, \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\lambda})). \end{aligned}$$

We will complete the proof by showing that h^+ is fully faithful.

Since λ has exponential cofinality $\geq \kappa$, the ∞ -category $\mathcal{S}_{<\lambda}$ admits κ -small limits (Example 7.6.6.11). Let $\text{Fun}(\widehat{\mathcal{E}} / \mathcal{C}, \mathcal{S}_{<\lambda})$ denote the relative exponential of Construction 4.5.9.1. By definition, objects of $\text{Fun}(\widehat{\mathcal{E}} / \mathcal{C}, \mathcal{S}_{<\lambda})$ can be identified with pairs $(C, \mathcal{G})$, where C is an object of $\mathcal{C}$ and $\mathcal{G} : \widehat{\mathcal{E}}_C \rightarrow \mathcal{S}_{<\lambda}$ is a functor. Let $\text{Fun}'(\widehat{\mathcal{E}} / \mathcal{C}, \mathcal{S}_{<\lambda})$ be the full subcategory spanned by those pairs $(C, \mathcal{F})$, where the functor $\mathcal{F}$ preserves κ -small limits. Let $\widehat{H} : \widehat{\mathcal{E}}^{\text{op}} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \times_{\mathcal{C}} \widehat{\mathcal{E}} \rightarrow \mathcal{S}_{<\lambda}$ be a relative Hom-functor for $\widehat{U}$, which we identify with a map

$$\widehat{h} : \widehat{\mathcal{E}}^{\text{op}} \rightarrow \text{Fun}_{/\mathcal{C}}(\text{Tw}(\mathcal{C}) / \mathcal{C}^{\text{op}}, \text{Fun}(\widehat{\mathcal{E}} / \mathcal{C}, \mathcal{S}_{<\lambda})).$$

Since corepresentable functors preserve limits (Corollary 7.4.1.19), the functor $\widehat{h}$ factors through the full subcategory $\text{Fun}_{/\mathcal{C}}(\text{Tw}(\mathcal{C}) / \mathcal{C}^{\text{op}}, \text{Fun}'(\widehat{\mathcal{E}} / \mathcal{C}, \mathcal{S}_{<\lambda}))$. Since F is fully faithful (Remark 8.7.1.7), the functor h^+ is isomorphic to the composition

$$\begin{aligned} \mathcal{E}^{\text{op}} &\xrightarrow{F^{\text{op}}} \widehat{\mathcal{E}}^{\text{op}} \\ &\xrightarrow{\widehat{h}} \text{Fun}_{/\mathcal{C}}(\text{Tw}(\mathcal{C}) / \mathcal{C}^{\text{op}}, \text{Fun}'(\widehat{\mathcal{E}} / \mathcal{C}, \mathcal{S}_{<\lambda})) \\ &\xrightarrow{T} \text{Fun}_{/\mathcal{C}}(\text{Tw}(\mathcal{C}) / \mathcal{C}^{\text{op}}, \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\lambda})), \end{aligned}$$

where T is given by precomposition with F . It follows from the universal property of Theorem 8.7.1.14 that precomposition with F induces an equivalence $\text{Fun}'(\widehat{\mathcal{E}} / \mathcal{C}, \mathcal{S}_{<\lambda}) \rightarrow \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\lambda})$ of inner fibrations over $\mathcal{C}$, so that T is an equivalence of ∞ -categories. To

complete the proof, it will suffice to show that the functor $\widehat{h}$ is fully faithful. In other words, we can replace U by $\widehat{U}$ (and κ by the cardinal λ) and thereby reduce to proving Lemma 8.7.7.8 under the assumption that U is a cocartesian fibration. In this case, the desired result follows from Lemma 8.7.7.7 (and Remark 8.7.1.7). $\square$

Proof of Theorem 8.7.7.4. Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a flat inner fibration of ∞ -categories which is essentially κ -small. It follows from Lemma 8.7.7.8 that a relative Hom-functor for U determines a fully faithful functor $h : \mathcal{E}^{\text{op}} \rightarrow \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger$. We wish to show that the diagram

$$\begin{array}{ccc} \mathcal{E}^{\text{op}} & \xrightarrow{h} & \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger \\ & \searrow U^{\text{op}} & \swarrow V^\dagger \\ & \mathcal{C}^{\text{op}} & \end{array}$$

exhibits $\text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger$ as a fiberwise κ -cocompletion of $\mathcal{E}^{\text{op}}$. By construction, $V^\dagger$ is a cartesian fibration which is conjugate to $V : \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa}) \rightarrow \mathcal{C}$. In particular, for every morphism $f : C \rightarrow C'$ of $\mathcal{C}$, the contravariant transport functor

$$\{C\} \times_{\mathcal{C}^{\text{op}}} \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger \rightarrow \{C'\} \times_{\mathcal{C}^{\text{op}}} \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger$$

for the cartesian fibration $V^\dagger$ can be identified with the covariant transport functor

$$\{C\} \times_{\mathcal{C}^{\text{op}}} \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa}) \rightarrow \{C'\} \times_{\mathcal{C}^{\text{op}}} \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})$$

for the cocartesian fibration V (see Proposition 8.6.1.5), and therefore preserves κ -small colimits (Lemma 8.7.7.2). By virtue of Proposition 8.7.1.12, it will suffice to show that for each object $C \in \mathcal{C}$, the map of fibers

$$h_C : \mathcal{E}_C^{\text{op}} \rightarrow \{C\} \times_{\mathcal{C}^{\text{op}}} \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger$$

exhibits $\{C\} \times_{\mathcal{C}^{\text{op}}} \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger$ as a κ -cocompletion of $\mathcal{E}_C^{\text{op}}$. Unwinding the definitions, we see that the composition of h_C with the equivalence

$$\{C\} \times_{\mathcal{C}^{\text{op}}} \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})^\dagger \simeq \{C\} \times_{\mathcal{C}} \text{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{S}_{<\kappa})$$

identifies with the contravariant Yoneda embedding for the ∞ -category $\mathcal{E}_C$. The desired result now follows from Theorem 8.4.3.2. $\square$

Chapter 9

Large ∞ -Categories

04KE 9.1 Filtered ∞ -Categories

05WY We begin by reviewing the classical notion of a filtered category.

02P9 **Definition 9.1.0.1.** Let $\mathcal{C}$ be a category. We say that $\mathcal{C}$ is *filtered* if it satisfies the following conditions:

- ($\ast_0$) The category $\mathcal{C}$ is nonempty.
- ($\ast_1$) For every pair of objects $X, Y \in \mathcal{C}$, there exists an object $Z \in \mathcal{C}$ and a pair of morphisms $u : X \rightarrow Z$ and $v : Y \rightarrow Z$.
- ($\ast_2$) For every pair of morphisms $f_0, f_1 : X \rightarrow Y$ in $\mathcal{C}$ having the same source and target, there exists a morphism $g : Y \rightarrow Z$ satisfying $g \circ f_0 = g \circ f_1$.

Our goal in this section is to formulate an ∞ -categorical counterpart of Definition 9.1.0.1. We say that an ∞ -category $\mathcal{C}$ is *filtered* if, for every finite simplicial set K , every diagram $f : K \rightarrow \mathcal{C}$ can be extended to the cone $K^\triangleright$ (Definition 9.1.1.1): that is, the coslice ∞ -category $\mathcal{C}_{f/}$ is nonempty. In §9.1.1, we show that if this property is satisfied for *every* finite diagram in $\mathcal{C}$, then we can say more: every such coslice ∞ -category $\mathcal{C}_{f/}$ is weakly contractible. It follows that $\mathcal{C}$ is filtered if and only if the diagonal map $\mathcal{C} \rightarrow \text{Fun}(K, \mathcal{C})$ is right cofinal for every finite simplicial set K (Proposition 9.1.1.18).

To verify that an ∞ -category $\mathcal{C}$ is filtered, it is not necessary to show that the coslice ∞ -category $\mathcal{C}_{f/}$ is nonempty for *every* finite diagram $f : K \rightarrow \mathcal{C}$. In §9.1.2, we show that it suffices to verify this condition in the special case where $K = \partial\Delta^n$ is the boundary of a standard simplex, for each $n \geq 0$ (Lemma 9.1.2.12). When $\mathcal{C} = N_\bullet(\mathcal{C}_0)$ is (the nerve of) an ordinary category $\mathcal{C}_0$, this condition is vacuous for $n > 2$, and reduces to condition ($\ast_n$) of Definition 9.1.0.1 for $n \leq 2$ (see Example 9.1.2.3 and Exercise 9.1.2.15). It follows that $\mathcal{C}_0$ is

a filtered category (in the sense of Definition 9.1.0.1) if and only if the nerve $\mathcal{C} = N_\bullet(\mathcal{C}_0)$ is a filtered ∞ -category.

Our primary interest in the notion of filtered ∞ -category stems from the exactness properties enjoyed by filtered colimits. Let $\mathcal{C}$ be a small ∞ -category, and let $\mathcal{S}$ denote the ∞ -category of spaces (Construction 5.5.1.1). In §9.1.5, we show that $\mathcal{C}$ is filtered if and only if the colimit functor $\varinjlim : \text{Fun}(\mathcal{C}, \mathcal{S}) \rightarrow \mathcal{S}$ preserves finite limits (Theorem 9.1.5.1). One implication is fairly straightforward: if the functor $\varinjlim$ preserves K -indexed limits, then the diagonal map $\mathcal{C} \rightarrow \text{Fun}(K^{\text{op}}, \mathcal{C})$ is right cofinal (Proposition 9.1.5.2). Allowing K to vary over all finite simplicial sets, we conclude that $\mathcal{C}$ is filtered. To prove the converse, we will need to work a bit harder. Assume that the ∞ -category $\mathcal{C}$ is filtered; we wish to show that the colimit functor $\varinjlim$ preserves finite limits. In §7.7.7, we show that this is equivalent to the following *a priori* weaker assertion (see Proposition 7.7.7.3):

- ($\star$) Let $\text{Fun}'(\mathcal{C}, \mathcal{S})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{S})$ spanned by those diagrams $\mathcal{F}$ for which the colimit $\varinjlim(\mathcal{F})$ is contractible. Then $\text{Fun}'(\mathcal{C}, \mathcal{S})$ is closed under finite limits.

To prove ($\star$), it will be convenient to work with another description of the subcategory $\text{Fun}'(\mathcal{C}, \mathcal{S})$. Recall that for any small diagram $\mathcal{F} : \mathcal{C} \rightarrow \mathcal{S}$, the colimit $\varinjlim(\mathcal{F})$ can be regarded as a fibrant replacement for the ∞ -category of elements $\int_{\mathcal{C}} \mathcal{F}$ (Corollary 7.4.3.3). In particular, the colimit $\varinjlim(\mathcal{F})$ is contractible if and only if the ∞ -category $\int_{\mathcal{C}} \mathcal{F}$ is weakly contractible. When $\mathcal{C}$ is filtered, we show in §9.1.3 that this is equivalent to the *a priori* stronger condition that the ∞ -category $\int_{\mathcal{C}} \mathcal{F}$ is also filtered (Corollary 9.1.3.4). In §9.1.5, we use this characterization to deduce ($\star$) (see Lemma 9.1.5.6) and thereby establish Theorem 9.1.5.1.

Let $U : \mathcal{D} \rightarrow \mathcal{C}$ be a functor of ∞ -categories. If U is right cofinal, then the colimit of any diagram $\mathcal{F} : \mathcal{C} \rightarrow \mathcal{S}$ can be identified with the colimit of the restriction $\mathcal{F} \circ U$. It follows that if the ∞ -category $\mathcal{D}$ is filtered, then the ∞ -category $\mathcal{C}$ is also filtered (Corollary 9.1.5.13). In §9.1.8, we establish a converse of this result: if $\mathcal{C}$ is a filtered ∞ -category, then there exists a filtered category $\mathcal{C}_0$ and a right cofinal functor $N_\bullet(\mathcal{C}_0) \rightarrow \mathcal{C}$. Moreover, we can even arrange that $\mathcal{C}_0$ is a partially ordered set (Theorem 9.1.8.1).

This book has already made extensive use of the theory of filtered colimits in the setting of ordinary categories, such as the category Set_Δ of simplicial sets. In this context, an essential feature of filtered colimits (not shared by colimits in general) is homotopy invariance: if $f : \{X_\alpha\} \rightarrow \{Y_\alpha\}$ is a levelwise homotopy equivalence between filtered diagrams of Kan complexes, then the colimit $\varinjlim(X_\alpha) \rightarrow \varinjlim(Y_\alpha)$ is also a homotopy equivalence (Proposition 3.2.8.3). In §9.1.6, we apply this observation to show that the inclusion functor $N_\bullet(\text{Kan}) \hookrightarrow N_\bullet^{\text{hc}}(\text{Kan}) = \mathcal{S}$ preserves filtered colimits (Variant 9.1.6.4). Consequently, questions about filtered colimits in the ∞ -category $\mathcal{S}$ can often be translated to concrete assertions about simplicial sets.

9.1.1 Filtered ∞ -Categories

02P8 Definition 9.1.0.1 has a counterpart in the setting of ∞ -categories.

02PB **Definition 9.1.1.1.** Let $\mathcal{C}$ be an ∞ -category. We say that $\mathcal{C}$ is *filtered* if, for every finite simplicial set K , every diagram $f : K \rightarrow \mathcal{C}$ admits an extension $\bar{f} : K^\triangleright \rightarrow \mathcal{C}$.

In §9.1.2, we will show that Definition 9.1.1.1 is a generalization of Definition 9.1.0.1: that is, a category $\mathcal{C}$ is filtered if and only if the ∞ -category $N_\bullet(\mathcal{C})$ is filtered (Corollary 9.1.2.8).

05WZ **Example 9.1.1.2.** Let $(A, \leq)$ be a partially ordered set. Then the ∞ -category $N_\bullet(A)$ is filtered if and only if $(A, \leq)$ is directed: that, every finite subset $A_0 \subseteq A$ has an upper bound.

02PC **Variant 9.1.1.3.** Let $\mathcal{C}$ be an ∞ -category. We say that $\mathcal{C}$ is *cofiltered* if, for every finite simplicial set K , every diagram $f : K \rightarrow \mathcal{C}$ admits an extension $\bar{f} : K^\triangleleft \rightarrow \mathcal{C}$. Equivalently, $\mathcal{C}$ is cofiltered if the opposite ∞ -category $\mathcal{C}^{\text{op}}$ is filtered.

It will sometimes be convenient to work with a generalization of Definition 9.1.1.1.

05X0 **Variant 9.1.1.4.** Let $\mathcal{C}$ be an ∞ -category and let κ be an infinite cardinal. We say that $\mathcal{C}$ is κ -*filtered* if, for every κ -small simplicial set K , every diagram $f : K \rightarrow \mathcal{C}$ admits an extension $\bar{f} : K^\triangleright \rightarrow \mathcal{C}$. We say that $\mathcal{C}$ is κ -*cofiltered* if the opposite ∞ -category $\mathcal{C}^{\text{op}}$ is κ -filtered.

05X1 **Example 9.1.1.5.** An ∞ -category $\mathcal{C}$ is filtered (in the sense of Definition 9.1.1.1) if and only if it is $\aleph_0$ -filtered (in the sense of Variant 9.1.1.4).

02PD **Example 9.1.1.6.** Let $\mathcal{C}$ be an ∞ -category which contains a final object X . Then every morphism of simplicial sets $f : K \rightarrow \mathcal{C}$ can be extended to a morphism $\bar{f} : K^\triangleright \rightarrow \mathcal{C}$ which carries the cone point of $K^\triangleright$ to the object X . In particular, the ∞ -category $\mathcal{C}$ is κ -filtered for every infinite cardinal κ . For a partial converse, see Proposition 9.1.8.11.

05X2 **Example 9.1.1.7.** Let $(A, \leq)$ be a partially ordered set and let κ be a cardinal. Then the ∞ -category $N_\bullet(A)$ is κ -filtered if and only if every κ -small subset $A_0 \subseteq A$ has an upper bound. If this condition is satisfied, we say that the partially ordered set $(A, \leq)$ is κ -*directed*.

06CE **Example 9.1.1.8.** Let $(A, \leq)$ be a nonempty linearly ordered set. Then the ∞ -category $N_\bullet(A)$ is automatically a filtered ∞ -category. If A has a largest element, then it is κ -filtered for every infinite cardinal κ . Otherwise, A is κ -filtered if and only if it has cofinality $\geq \kappa$ (see Definition 4.7.1.28).

In particular, if κ is a regular cardinal, then the ∞ -category $N_\bullet(\text{Ord}_{<\kappa})$ is κ -filtered (but not λ -filtered for $\lambda > \kappa$).

Example 9.1.1.9. Let $\mathbf{Idem}$ be the category introduced in Construction 8.5.2.7, comprised of a single object X and a single non-identity morphism $e : X \rightarrow X$ satisfying $e \circ e = e$. Then any diagram $f : K \rightarrow \mathbf{N}_\bullet(\mathbf{Idem})$ admits an extension $\bar{f} : K^\triangleright \rightarrow \mathbf{N}_\bullet(\mathbf{Idem})$, characterized by the requirement that for each vertex $k \in K$, the composition

$$\Delta^1 \simeq \{k\}^\triangleright \hookrightarrow K^\triangleright \xrightarrow{\bar{f}} \mathbf{N}_\bullet(\mathbf{Idem})$$

is the morphism e . It follows that the ∞ -category $\mathbf{N}_\bullet(\mathbf{Idem})$ is κ -filtered for every infinite cardinal κ (see Exercise 8.5.2.9).

Remark 9.1.1.10 (Monotonicity). Let $\mathcal{C}$ be an ∞ -category and let $\kappa \leq \lambda$ be infinite cardinals. If $\mathcal{C}$ is λ -filtered, then it is κ -filtered. In particular, if $\mathcal{C}$ is λ -filtered, then it is filtered.

Remark 9.1.1.11 (Products). Let κ be an infinite cardinal and let $\{\mathcal{C}_i\}_{i \in I}$ be a collection of κ -filtered ∞ -categories. Then the product $\mathcal{C} = \prod_{i \in I} \mathcal{C}_i$ is also a κ -filtered ∞ -category.

Remark 9.1.1.12. Let $\mathcal{C}$ be an ∞ -category and let κ be a singular cardinal. Then $\mathcal{C}$ is κ -filtered if and only if it is κ' -filtered, for every infinite cardinal $\kappa' < \kappa$. We will soon see that this is also equivalent to the requirement that $\mathcal{C}$ is κ^+ -filtered (Corollary 9.1.5.12). Consequently, there is generally no harm in restricting Variant 9.1.1.4 to the special case where κ is a regular cardinal.

Remark 9.1.1.13. Let $\mathcal{C}$ be an ∞ -category and let κ be an infinite cardinal. The following conditions are equivalent:

- (1) The ∞ -category $\mathcal{C}$ is κ -filtered.
- (2) For every κ -small simplicial set K and every diagram $f : K \rightarrow \mathcal{C}$, the coslice ∞ -category $\mathcal{C}_{f/}$ is nonempty.
- (3) For every κ -small simplicial set K and every diagram $f : K \rightarrow \mathcal{C}$, the oriented fiber product $\{f\} \tilde{\times}_{\mathbf{Fun}(K, \mathcal{C})} \mathcal{C}$ is nonempty.
- (4) For every κ -small simplicial set K and every diagram $f : K \rightarrow \mathcal{C}$, there exists a morphism $f \rightarrow f'$ in the ∞ -category $\mathbf{Fun}(K, \mathcal{C})$, where $f' : K \rightarrow \mathcal{C}$ is a constant diagram.

The equivalences (1) $\Leftrightarrow$ (2) and (3) $\Leftrightarrow$ (4) follow immediately from the definitions, and the equivalence (2) $\Leftrightarrow$ (3) follows from Theorem 4.6.4.19.

Remark 9.1.1.14. In the situation of Remark 9.1.1.13, suppose that κ is uncountable. If $\mathcal{C}$ is κ -filtered, then it satisfies the following *a priori* stronger versions of conditions (2), (3), and (4):

- (2') For every essentially κ -small simplicial set K and every diagram $f : K \rightarrow \mathcal{C}$, the coslice ∞ -category $\mathcal{C}_{f/}$ is nonempty.
- (3') For every essentially κ -small simplicial set K and every diagram $f : K \rightarrow \mathcal{C}$, the oriented fiber product $\{f\} \tilde{\times}_{\mathrm{Fun}(K, \mathcal{C})} \mathcal{C}$ is nonempty.
- (4') For every essentially κ -small simplicial set K and every diagram $f : K \rightarrow \mathcal{C}$, there exists a morphism $f \rightarrow f'$ in the ∞ -category $\mathrm{Fun}(K, \mathcal{C})$, where $f' : K \rightarrow \mathcal{C}$ is a constant diagram.

The implication (4) $\Rightarrow$ (4') follows by choosing a categorical equivalence $K \rightarrow \mathcal{K}$, where $\mathcal{K}$ is a κ -small ∞ -category. The equivalence (3') $\Leftrightarrow$ (4') is immediate, and the equivalence (2') $\Leftrightarrow$ (3') follows from Theorem 4.6.4.19.

0618 Remark 9.1.1.15. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a Morita equivalence of ∞ -categories (Definition 8.5.6.1) and let κ be an infinite cardinal. If $\mathcal{D}$ is κ -filtered, then $\mathcal{C}$ is also κ -filtered. To prove this, we can replace $\mathcal{C}$ by its essential image and thereby reduce to the case where $\mathcal{C}$ is a full subcategory of $\mathcal{D}$. If $f : K \rightarrow \mathcal{C}$ is a κ -small diagram, then our assumption that $\mathcal{D}$ is κ -filtered guarantees that there exists a natural transformation $f \rightarrow \underline{Y}$, for some object $Y \in \mathcal{D}$. Since F is a Morita equivalence, the object Y is a retract of some object $X \in \mathcal{C}$. It follows that there is also a natural transformation from f to the constant diagram $\underline{X}$.

02PG Proposition 9.1.1.16 (Coslices of Filtered ∞ -Categories). *Let κ be an infinite cardinal, let $\mathcal{C}$ be a κ -filtered ∞ -category and let $f : K \rightarrow \mathcal{C}$ be a diagram, where K is a κ -small simplicial set. Then the ∞ -category $\mathcal{C}_{f/}$ is also κ -filtered.*

Proof. By virtue of Remark 9.1.1.13, it will suffice to show that for every κ -small simplicial set L and every morphism $g : L \rightarrow \mathcal{C}_{f/}$, the ∞ -category $(\mathcal{C}_{f/})_{g/}$ is nonempty. Unwinding the definitions, we can identify g with a morphism of simplicial sets $\bar{f} : K \star L \rightarrow \mathcal{C}$ satisfying $\bar{f}|_K = f$. This identification supplies an isomorphism $(\mathcal{C}_{f/})_{g/} \simeq \mathcal{C}_{\bar{f}/}$. We are therefore reduced to showing that the coslice ∞ -category $\mathcal{C}_{\bar{f}/}$ is nonempty. This follows from Remark 9.1.1.13, since the simplicial set $K \star L$ is κ -small (Corollary 4.7.4.13). $\square$

02PH Proposition 9.1.1.17. *Let $\mathcal{C}$ be a filtered ∞ -category. Then $\mathcal{C}$ is weakly contractible.*

Proof. By virtue of Proposition 3.1.7.1, there exists a functor $Q : \mathrm{Set}_\Delta \rightarrow \mathrm{Set}_\Delta$ and a natural transformation $u : \mathrm{id}_{\mathrm{Set}_\Delta} \rightarrow Q$ with the following properties:

- The functor Q commutes with filtered colimits.
- For every simplicial set X , the simplicial set $Q(X)$ is a Kan complex.
- For every simplicial set X , the morphism $u_X : X \rightarrow Q(X)$ is a weak homotopy equivalence.

To show that $\mathcal{C}$ is weakly contractible, it will suffice to show that the Kan complex $Q(\mathcal{C})$ is contractible: that is, for every integer $n \geq 0$, every morphism of simplicial sets $\sigma : \partial\Delta^n \rightarrow Q(\mathcal{C})$ is nullhomotopic (see Variant 3.2.4.12). Since the simplicial set $\partial\Delta^n$ is finite and the functor Q commutes with filtered colimits, the morphism σ factors as a composition $\partial\Delta^n \rightarrow Q(K) \xrightarrow{Q(\iota)} Q(\mathcal{C})$, where K is a finite simplicial subset of $\mathcal{C}$ and $\iota : K \hookrightarrow \mathcal{C}$ denotes the inclusion map. We will complete the proof by showing that $Q(\iota)$ is nullhomotopic. Since $u_K : K \rightarrow Q(K)$ is a weak homotopy equivalence, this is equivalent to assertion that the composite morphism $Q(\iota) \circ u_K = u_{\mathcal{C}} \circ \iota$ is nullhomotopic. This is clear: our assumption that $\mathcal{C}$ is filtered guarantees that there exists a natural transformation from ι to a constant diagram $K \rightarrow \mathcal{C}$ (Remark 9.1.1.13). $\square$

Proposition 9.1.1.18. *Let $\mathcal{C}$ be an ∞ -category and let κ be an infinite cardinal. The following conditions are equivalent:* 02PJ

- (1) *The ∞ -category $\mathcal{C}$ is κ -filtered.*
- (2) *For every κ -small simplicial set K and every morphism $f : K \rightarrow \mathcal{C}$, the ∞ -category $\mathcal{C}_{f/}$ is κ -filtered.*
- (3) *For every κ -small simplicial set K and every morphism $f : K \rightarrow \mathcal{C}$, the ∞ -category $\mathcal{C}_{f/}$ is filtered.*
- (4) *For every κ -small simplicial set and every morphism $f : K \rightarrow \mathcal{C}$, the ∞ -category $\mathcal{C}_{f/}$ is weakly contractible.*
- (5) *For every κ -small simplicial set K , the diagonal map $\delta : \mathcal{C} \rightarrow \text{Fun}(K, \mathcal{C})$ is right cofinal.*

Proof. The implication (1) $\Rightarrow$ (2) follows from Proposition 9.1.1.16, the implication (2) $\Rightarrow$ (3) from Remark 9.1.1.10, the implication (3) $\Rightarrow$ (4) Proposition 9.1.1.17, and the implication (4) $\Rightarrow$ (1) is immediate from the definitions (Remark 9.1.1.13). The equivalence (4) $\Leftrightarrow$ (5) is a special case of Corollary 7.2.3.9. $\square$

Corollary 9.1.1.19. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be an equivalence of ∞ -categories and let κ be an infinite cardinal. Then $\mathcal{C}$ is κ -filtered if and only if $\mathcal{D}$ is κ -filtered.* 02PK

Proof. By virtue of Proposition 9.1.1.18, it will suffice to show that for every (κ -small) simplicial set K , the diagonal map $\delta_{\mathcal{C}} : \mathcal{C} \rightarrow \text{Fun}(K, \mathcal{C})$ is right cofinal if and only if the diagonal map $\delta_{\mathcal{D}} : \mathcal{D} \rightarrow \text{Fun}(K, \mathcal{D})$ is right cofinal. This follows by applying Corollary

7.2.1.22 to the commutative diagram of ∞ -categories

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{\delta_{\mathcal{C}}} & \mathrm{Fun}(K, \mathcal{C}) \\ \downarrow F & & \downarrow F \circ \\ \mathcal{D} & \xrightarrow{\delta_{\mathcal{D}}} & \mathrm{Fun}(K, \mathcal{D}). \end{array}$$

□

02PL **Corollary 9.1.1.20.** *Let $\mathcal{C}$ be a Kan complex. Then $\mathcal{C}$ is filtered if and only if it is contractible.*

Proof. If $\mathcal{C}$ is a contractible Kan complex, then there exists a categorical equivalence $\mathcal{C} \rightarrow \Delta^0$, so that $\mathcal{C}$ is filtered by virtue of Corollary 9.1.1.19. The converse is a special case of Proposition 9.1.1.17. □

9.1.2 Local Characterization of Filtered ∞ -Categories

02PM Let $\mathcal{C}$ be an ∞ -category and let $\mathrm{h}\mathcal{C}$ denote the homotopy category of $\mathcal{C}$, which we view as enriched over the homotopy category hKan of Kan complexes (see Construction 4.6.9.13). In this section, we show that the condition that $\mathcal{C}$ is filtered can be formulated entirely in terms of $\mathrm{h}\mathcal{C}$, together with its hKan -enrichment (Theorem 9.1.2.5).

02PN **Definition 9.1.2.1.** Let hKan denote the homotopy category of Kan complexes (Construction 7.2.1.22), and let $\mathcal{C}$ be a category which is enriched over hKan . We will say that $\mathcal{C}$ is *homotopy filtered* if it is nonempty and satisfies the following condition for each $n \geq 1$:

($*_n$) For every pair of objects $X, Y \in \mathcal{C}$ and for every morphism of simplicial sets $\sigma : \partial\Delta^{n-1} \rightarrow \underline{\mathrm{Hom}}_{\mathcal{C}}(X, Y)$, there exists a morphism $v : Y \rightarrow Z$ for which the composite morphism

$$\partial\Delta^{n-1} \xrightarrow{\sigma} \underline{\mathrm{Hom}}_{\mathcal{C}}(X, Y) \xrightarrow{v \circ} \underline{\mathrm{Hom}}_{\mathcal{C}}(X, Z)$$

is nullhomotopic.

02PP **Warning 9.1.2.2.** In the formulation of condition ($*_n$) of Definition 9.1.2.1, postcomposition with v defines a map of Kan complexes $V : \underline{\mathrm{Hom}}_{\mathcal{C}}(X, Y) \rightarrow \underline{\mathrm{Hom}}_{\mathcal{C}}(X, Z)$ which is only well-defined up to homotopy. However, the condition that $V \circ \sigma$ is nullhomotopic depends only on the homotopy class of V .

02PQ **Example 9.1.2.3.** Let $\mathcal{C}$ be an ordinary category, which we regard as an hKan -enriched category in which each of the Kan complexes $\underline{\mathrm{Hom}}_{\mathcal{C}}(X, Y)$ is a constant simplicial set. In this case, condition ($*_n$) of Definition 9.1.2.1 is automatically satisfied for $n \geq 3$. Moreover, we can state conditions ($*_1$) and ($*_2$) more concretely as follows:

- ($\ast_1$) For every pair of objects $X, Y \in \mathcal{C}$, there exists an object $Z \in \mathcal{C}$ equipped with morphisms $u : X \rightarrow Z$ and $v : Y \rightarrow Z$.
- ($\ast_2$) For every pair of objects $X, Y \in \mathcal{C}$ and every pair of morphisms $f_0, f_1 : X \rightarrow Y$, there exists a morphism $v : Y \rightarrow Z$ satisfying $v \circ f_0 = v \circ f_1$.

It follows that $\mathcal{C}$ is homotopy filtered (in the sense of Definition 9.1.2.1) if and only if it is filtered (in the sense of Definition 9.1.0.1).

Remark 9.1.2.4. Let $\mathcal{C}$ be an hKan-enriched category. If $\mathcal{C}$ is homotopy filtered (in the sense of Definition 9.1.2.1), then it is filtered when regarded as an ordinary category (in the sense of Definition 9.1.0.1). Beware that the converse is false in general (see Warning 9.1.2.7).

We can now state the main result of this section:

Theorem 9.1.2.5. *Let $\mathcal{C}$ be an ∞ -category. Then $\mathcal{C}$ is filtered (in the sense of Definition 9.1.1.1) if and only if the homotopy category $\mathrm{h}\mathcal{C}$ is homotopy filtered (in the sense of Definition 9.1.2.1), when regarded as an hKan-enriched category (see Construction 4.6.9.13).*

Before giving the proof of Theorem 9.1.2.5, let us note some of its consequences.

Corollary 9.1.2.6. *Let $\mathcal{C}$ be a filtered ∞ -category (in the sense of Definition 9.1.1.1). Then $\mathrm{h}\mathcal{C}$ is a filtered category (in the sense of Definition 9.1.0.1).*

Proof. Combine Theorem 9.1.2.5 with Remark 9.1.2.4. □

Warning 9.1.2.7. The converse of Corollary 9.1.2.6 is false. For example, if $\mathcal{C}$ is a simply connected Kan complex, then the homotopy category $\mathrm{h}\mathcal{C}$ is automatically filtered. However, $\mathcal{C}$ is filtered if and only if it is contractible (Corollary 9.1.1.20).

Corollary 9.1.2.8. *A category $\mathcal{C}$ is filtered (in the sense of Definition 9.1.0.1) if and only if the ∞ -category $\mathrm{N}_\bullet(\mathcal{C})$ is filtered (in the sense of Definition 9.1.1.1).*

Proof. Combine Theorem 9.1.2.5 with Example 9.1.2.3. □

Corollary 9.1.2.9. *Let $\mathcal{C}$ be a locally Kan simplicial category. Then the ∞ -category $\mathrm{N}_\bullet^{\mathrm{hc}}(\mathcal{C})$ is filtered if and only if the homotopy category $\mathrm{h}\mathcal{C}$ is homotopy filtered, when regarded as an hKan-enriched category.*

Proof. Combine Theorem 9.1.2.5 with Corollary 4.6.9.20. □

Exercise 9.1.2.10. Let $\mathcal{C}$ be a $(2, 1)$ -category (Definition 2.2.8.5). Show that the Duskin nerve $\mathrm{N}_\bullet^{\mathrm{D}}(\mathcal{C})$ is a filtered ∞ -category if and only if $\mathcal{C}$ satisfies the following conditions:

- ($\ast_0$) The collection of objects $\text{Ob}(\mathcal{C})$ is nonempty.
- ($\ast_1$) For every pair of objects $X, Y \in \mathcal{C}$, there exists an object $Z \in \mathcal{C}$ and a pair of 1-morphisms $f : X \rightarrow Z$ and $g : Y \rightarrow Z$.
- ($\ast_2$) For every pair of objects $X, Y \in \mathcal{C}$ and every pair of 1-morphisms $f, g : X \rightarrow Y$, there exists a 1-morphism $h : Y \rightarrow Z$ such that the 1-morphisms $h \circ f$ and $h \circ g$ are isomorphic (when viewed as objects of the category $\underline{\text{Hom}}_{\mathcal{C}}(X, Z)$).
- ($\ast_3$) For every 1-morphism $f : X \rightarrow Y$ in $\mathcal{C}$ and every 2-morphism $\gamma : f \Rightarrow f$, there exists a 1-morphism $g : Y \rightarrow Z$ for which the horizontal composition $\text{id}_g \circ \gamma$ is equal to the identity 2-morphism $\text{id}_{g \circ f}$.

We now turn to the proof of Theorem 9.1.2.5. The easy part is to show that if $\mathcal{C}$ is a filtered ∞ -category, then the homotopy category $\text{h}\mathcal{C}$ is homotopy filtered. Condition ($\ast_n$) of Definition 9.1.2.1 is a special case of the following assertion:

02PZ **Lemma 9.1.2.11.** *Let κ be an infinite cardinal, let $\mathcal{C}$ be a κ -filtered ∞ -category containing objects X and Y , and let K be a κ -small simplicial set equipped with a morphism $f : K \rightarrow \text{Hom}_{\mathcal{C}}(X, Y)$. Then there exists a morphism $v : Y \rightarrow Z$ of $\mathcal{C}$ for which the composition $K \xrightarrow{f} \text{Hom}_{\mathcal{C}}(X, Y) \xrightarrow{v \circ} \text{Hom}_{\mathcal{C}}(X, Z)$ is nullhomotopic.*

Proof. Let $\Sigma(K)$ denote the iterated coproduct

$$\{x\} \coprod_{(\{0\} \times K)} (\Delta^1 \times K) \coprod_{(\{1\} \times K)} \{y\},$$

so that we can identify f with a morphism of simplicial sets $F : \Sigma(K) \rightarrow \mathcal{C}$ satisfying $F(x) = X$ and $F(y) = Y$. Note that $\Sigma(K)$ is κ -small, so our assumption that $\mathcal{C}$ is κ -filtered guarantees that we can extend F to a morphism of simplicial set $\overline{F} : \Sigma(K) \star \{z\} \rightarrow \mathcal{C}$. Set $Z = \overline{F}(z)$. Then $\overline{F}$ carries $\{x\} \star \{z\}$ and $\{y\} \star \{z\}$ to morphisms $u : X \rightarrow Z$ and $v : Y \rightarrow Z$ in $\mathcal{C}$. Moreover, the natural map $\Delta^1 \times K \rightarrow \Sigma(K)$ admits a unique extension $q : \Delta^2 \times K \rightarrow \Sigma(K) \star \{z\}$ carrying $\{2\} \times K$ to the vertex z , and the composition

$$\Delta^2 \times K \xrightarrow{q} \Sigma(K) \star \{z\} \xrightarrow{\overline{F}} \mathcal{C}$$

determines a morphism from K to the simplicial set $\text{Hom}_{\mathcal{C}}(X, Y, Z)$ of Construction 4.6.9.9.

Unwinding the definitions, we see that the diagram of simplicial sets

$$\begin{array}{ccc}
 K & \xrightarrow{(v,f)} & \mathrm{Hom}_{\mathcal{C}}(Y, Z) \times \mathrm{Hom}_{\mathcal{C}}(X, Y) \\
 & \searrow g & \uparrow \\
 & & \mathrm{Hom}_{\mathcal{C}}(X, Y, Z) \\
 & & \downarrow \\
 \Delta^0 & \xrightarrow{u} & \mathrm{Hom}_{\mathcal{C}}(X, Z)
 \end{array}$$

is strictly commutative, from which we immediately deduce (from the definition of the composition law on $\mathcal{C}$) that the composition $K \xrightarrow{f} \mathrm{Hom}_{\mathcal{C}}(X, Y) \xrightarrow{v \circ} \mathrm{Hom}_{\mathcal{C}}(X, Z)$ is homotopic to the constant map taking the value u . $\square$

The difficult half of Theorem 9.1.2.5 will require some further preliminaries. We first note that, to verify that an ∞ -category $\mathcal{C}$ is filtered, it suffices to verify the extension condition of Definition 9.1.1.1 in the special case where $K = \partial\Delta^n$ is the boundary of a simplex.

Lemma 9.1.2.12. *An ∞ -category $\mathcal{C}$ is filtered if and only if it satisfies the following condition for every integer $n \geq 0$:*

$(*_n')$ *Every morphism of simplicial sets $\partial\Delta^n \rightarrow \mathcal{C}$ can be extended to a morphism $(\partial\Delta^n)^\triangleright \rightarrow \mathcal{C}$.*

Proof. The necessity of condition $(*_n')$ is clear. For the converse, suppose that $\mathcal{C}$ satisfies $(*_n')$ for each $n \geq 0$. We wish to prove that $\mathcal{C}$ is filtered. Let $f : K \rightarrow \mathcal{C}$ be a diagram where K is a finite simplicial set; we wish to show that the ∞ -category $\mathcal{C}_{f/}$ is nonempty. If $K = \emptyset$, then this follows immediately from assumption $(*_0')$. Otherwise, the simplicial set K has dimension m for some integer $m \geq 0$. We proceed by induction on m and on the number of nondegenerate m -simplices of K . Choose a nondegenerate m -simplex $\sigma : \Delta^m \rightarrow K$. Using Proposition 1.1.4.12, we can choose a pushout diagram

$$\begin{array}{ccc}
 \partial\Delta^m & \longrightarrow & \Delta^m \\
 \downarrow & & \downarrow \sigma \\
 K' & \longrightarrow & K
 \end{array}$$

where $K' \subseteq K$ is a simplicial subset having a smaller number of nondegenerate m -simplices. Set $f' = f|_{K'}$, $f_0 = f \circ \sigma$, and $f'_0 = f'_0 \circ \sigma|_{\partial\Delta^m}$, so that we have a pullback diagram of

∞ -categories

$$\begin{array}{ccc} \mathcal{C}_{f/} & \longrightarrow & \mathcal{C}_{f'/} \\ \downarrow & & \downarrow \Phi \\ \mathcal{C}_{f_0/} & \xrightarrow{\Psi} & \mathcal{C}_{f'_0/} . \end{array}$$

Applying our inductive hypothesis, we deduce that the ∞ -category $\mathcal{C}_{f'/}$ is nonempty. Choose an object X of $\mathcal{C}_{f'/}$, so that $\Phi(X) \in \mathcal{C}_{f_{\partial\Delta}/}$ can be identified with a morphism of simplicial sets $g : (\partial\Delta^m)^{\triangleright} \rightarrow \mathcal{C}$. Amalgamating $f \circ \sigma$ with g , we obtain a morphism of simplicial sets

$$\bar{g} : \partial\Delta^{m+1} \simeq (\partial\Delta^m)^{\triangleright} \coprod_{\partial\Delta^m} \Delta^m \rightarrow \mathcal{C} .$$

Invoking $(*_m)$, we conclude that $\bar{g}$ can be extended to a morphism of simplicial sets $(\partial\Delta^{m+1})^{\triangleright} \rightarrow \mathcal{C}$. Unwinding the definitions, we see that this extension supplies an object $Y \in \mathcal{C}_{f_0/}$ together with a morphism $u : \Phi(X) \rightarrow \Psi(Y)$ in the ∞ -category $\mathcal{C}_{f'_0/}$.

Note that the projection maps $\mathcal{C}_{f'/} \rightarrow \mathcal{C} \leftarrow \mathcal{C}_{f'_0/}$ are left fibrations (Proposition 4.3.6.1). Let $\bar{X}$ denote the image of X in the ∞ -category $\mathcal{C}$, so that Corollary 4.3.7.13 guarantees that the vertical maps in the diagram

$$\begin{array}{ccc} (\mathcal{C}_{f'/})_{X/} & \xrightarrow{\Phi_{X/}} & (\mathcal{C}_{f'_0/})_{U(X)/} \\ & \searrow & \swarrow \\ & \mathcal{C}_{\bar{X}/} & \end{array}$$

are trivial Kan fibrations. In particular, they are equivalences of ∞ -categories, so that the functor $\Phi_{X/}$ is also an equivalence of ∞ -categories. It follows that we can choose a morphism $w : X \rightarrow Z$ in the ∞ -category $\mathcal{C}_{f'/}$ and a 2-simplex

$$\begin{array}{ccc} & \Psi(Y) & \\ u \nearrow & & \searrow v \\ \Phi(X) & \xrightarrow{\Phi(w)} & \Phi(Z) \end{array}$$

in the ∞ -category $\mathcal{C}_{f'_0/}$, where v is an isomorphism. Since Ψ is a left fibration (Corollary 4.3.6.12), we can lift v to a morphism $\tilde{v} : Y \rightarrow \tilde{Z}$ of the ∞ -category $\mathcal{C}_{f_0/}$. The pair $(Z, \tilde{Z})$ can then be regarded as an object of the ∞ -category $\mathcal{C}_{f/} = \mathcal{C}_{f'/} \times_{\mathcal{C}_{f'_0/}} \mathcal{C}_{f_0/}$. $\square$

Remark 9.1.2.13. Let $\mathcal{C}$ be an ∞ -category and let $n \geq 0$ be a nonnegative integer. 02Q1 Condition $(*_n')$ of Lemma 9.1.2.12 is equivalent to the assertion that, for every morphism of simplicial sets $f : \partial\Delta^n \rightarrow \mathcal{C}$, the coslice ∞ -category $\mathcal{C}_{f/}$ is nonempty. By virtue of Theorem 4.6.4.19, this is equivalent to the requirement that the oriented fiber product $\{f\} \tilde{\times}_{\text{Fun}(\partial\Delta^n, \mathcal{C})} \mathcal{C}$ is nonempty. We can therefore reformulate $(*_n')$ as follows:

$(*_n')$ For every diagram $f : \partial\Delta^n \rightarrow \mathcal{C}$, there exists an object $C \in \mathcal{C}$ and a natural transformation $f \rightarrow \underline{C}$, where $\underline{C} : \partial\Delta^n \rightarrow \mathcal{C}$ is the constant morphism taking the value C .

For each integer $n \geq 1$, let us identify the standard simplex Δ^{n-1} with its image in $\partial\Delta^n \subset \Delta^n$ (given by the face opposite the n th vertex).

Lemma 9.1.2.14. Let $\mathcal{C}$ be an ∞ -category and let $n \geq 1$ be an integer. Then condition $(*_n')$ 02Q2 of Lemma 9.1.2.12 is equivalent to the following:

$(*_n'')$ Let $f : \partial\Delta^n \rightarrow \mathcal{C}$ be a morphism of simplicial sets for which the restriction $f|_{\Delta^{n-1}}$ is constant. Then f can be extended to a morphism $\bar{f} : (\partial\Delta^n)^\triangleright \rightarrow \mathcal{C}$.

Proof. The implication $(*_n') \Rightarrow (*_n'')$ is immediate. We will prove the converse. Assume that $(*_n'')$ is satisfied, and let $g : \partial\Delta^n \rightarrow \mathcal{C}$ be an arbitrary morphism of simplicial sets; we wish to show that g can be extended to a morphism $\bar{g} : (\partial\Delta^n)^\triangleright \rightarrow \mathcal{C}$. If $n = 1$, this follows immediately from $(*_n'')$; we will therefore assume that $n \geq 2$. Note that we can write $\partial\Delta^n$ as the union of Δ^{n-1} and the horn Λ_n^n , whose intersection is the simplicial subset $\partial\Delta^{n-1} \subset \Delta^{n-1}$. Set

$$g_- = g|_{\Delta^{n-1}} \quad g_\pm = g|_{\partial\Delta^{n-1}} \quad g_+ = g|_{\Lambda_n^n}.$$

Let $X = g(0)$ and $Y = g(n)$ and let $\pi : \mathcal{C}_{/Y} \rightarrow \mathcal{C}$ denote the projection map, so that we can identify g_+ with a morphism $\tilde{g}_\pm : \partial\Delta^{n-1} \rightarrow \mathcal{C}_{/Y}$ satisfying $\pi \circ \tilde{g}_\pm = g_\pm$.

Let $f_- : \Delta^{n-1} \rightarrow \mathcal{C}$ be the constant morphism taking the value X , and let $h_- : f_- \rightarrow g_-$ be the natural transformation given by the composite map

$$\Delta^1 \times \Delta^{n-1} \xrightarrow{(i,j) \mapsto ij} \Delta^{n-1} \xrightarrow{g_-} \mathcal{C}.$$

Set $f_\pm = f_-|_{\partial\Delta^{n-1}}$ and $h_\pm = h_-|_{\Delta^1 \times \partial\Delta^{n-1}}$, so that $h_\pm$ can be regarded as a natural transformation from $f_\pm$ to $g_\pm$. Since π is a right fibration, we can lift $h_\pm$ to a natural transformation $\tilde{h}_\pm : \tilde{f}_\pm \rightarrow \tilde{g}_\pm$ in the ∞ -category $\text{Fun}(\partial\Delta^{n-1}, \mathcal{C}_{/Y})$. Let us identify $\tilde{f}_\pm$ with a morphism of simplicial sets $f_+ : \Lambda_n^n \rightarrow \mathcal{C}$ satisfying $f_+(n) = Y$. Then $\tilde{h}_\pm$ determines a natural transformation $h_+ : f_+ \rightarrow g_+$, given by the composition

$$\Delta^1 \times \Lambda_n^n \simeq \Delta^1 \times (\partial\Delta^{n-1})^\triangleright \rightarrow (\Delta^1 \times \partial\Delta^{n-1})^\triangleright \xrightarrow{\tilde{h}_\pm} (\mathcal{C}_{/Y})^\triangleright \rightarrow \mathcal{C}.$$

Note that f_- and f_+ can be amalgamated to a morphism $f : \partial\Delta^n \rightarrow \mathcal{C}$, and that h_- and h_+ can be amalgamated to a natural transformation $h : f \rightarrow g$ in $\text{Fun}(\partial\Delta^n, \mathcal{C})$.

Invoking hypothesis $(*_n'')$, we see that f can be extended to a morphism $\bar{f} : (\partial\Delta^n)^\triangleright \rightarrow \mathcal{C}$. Let $Z \in \mathcal{C}$ denote the image under $\bar{f}$ of the cone point and let $\varphi : \mathcal{C}_{/Z} \rightarrow \mathcal{C}$ denote the projection map, so that $\bar{f}$ can be identified with a morphism of simplicial sets $f' : \partial\Delta^n \rightarrow \mathcal{C}_{/Z}$ satisfying $\varphi \circ f' = f$. Let us identify the vertex $f'(n) \in \mathcal{C}_{/Z}$ with a morphism $v : Y \rightarrow Z$ in the ∞ -category $\mathcal{C}$, so that we have a commutative diagram

$$\begin{array}{ccc} \mathcal{C}_{/v} & \xrightarrow{\varphi'} & \mathcal{C}_{/Y} \\ \downarrow \pi' & & \downarrow \pi \\ \mathcal{C}_{/Z} & \xrightarrow{\varphi} & \mathcal{C}. \end{array}$$

Set $f'_+ = f'|_{\Lambda_n^n}$ and $f'_\pm = f'|_{\partial\Delta^{n-1}}$, so that we can identify f'_+ with a morphism $\tilde{f}'_\pm : \partial\Delta^{n-1} \rightarrow \mathcal{C}_{/v}$ satisfying $\pi' \circ \tilde{f}'_\pm = f'_+$. Since the inclusion $\{0\} \hookrightarrow \Delta^1$ is left anodyne, the morphism $\varphi' : \mathcal{C}_{/v} \rightarrow \mathcal{C}_{/Y}$ is a trivial Kan fibration (Corollary 4.3.6.14). We can therefore lift $\tilde{h}_\pm$ to a natural transformation $\tilde{h}'_\pm : \tilde{f}'_\pm \rightarrow \tilde{g}'_\pm$ for some morphism $\tilde{g}'_\pm : \partial\Delta^{n-1} \rightarrow \mathcal{C}_{/v}$. Let us identify $\tilde{g}'_\pm$ with a morphism $g'_\pm : \Lambda_n^n \rightarrow \mathcal{C}_{/Z}$ satisfying $\varphi \circ g'_\pm = g_\pm$. Then $\tilde{h}'_\pm$ determines a natural transformation $h'_\pm : f'_\pm \rightarrow g'_\pm$, given by the composition

$$\Delta^1 \times \Lambda_n^n \simeq \Delta^1 \times (\partial\Delta^{n-1})^\triangleright \rightarrow (\Delta^1 \times \partial\Delta^{n-1})^\triangleright \xrightarrow{\tilde{h}'_\pm} (\mathcal{C}_{/v})^\triangleright \rightarrow \mathcal{C}_{/Z}.$$

Let e denote the restriction $h'_+|_{\Delta^1 \times \{0\}}$, which we regard as an edge of the simplicial set $\mathcal{C}_{/Z}$. By construction, $\varphi(e)$ is the degenerate edge id_X of $\mathcal{C}$. Since φ is a right fibration (Proposition 4.3.6.1), it follows that e is an isomorphism in $\mathcal{C}_{/Z}$ (Proposition 4.4.2.11). Applying Proposition 4.4.5.8, we deduce that the lifting problem

$$\begin{array}{ccc} (\Delta^1 \times \Lambda_n^n) \amalg_{(\{0\} \times \Lambda_n^n)} (\{0\} \times \partial\Delta^n) & \xrightarrow{(h'_+, f')} & \mathcal{C}_{/Z} \\ \downarrow & \nearrow h' & \downarrow \varphi \\ \Delta^1 \times \partial\Delta^n & \xrightarrow{h} & \mathcal{C} \end{array}$$

admits a solution. The morphism h' is then a natural transformation from f' to a morphism $g' : \partial\Delta^n \rightarrow \mathcal{C}_{/Z}$, which we can identify with a map $\bar{g} : (\partial\Delta^n)^\triangleright \rightarrow \mathcal{C}$ satisfying $\bar{g}|_{\partial\Delta^n} = g$. $\square$

Proof of Theorem 9.1.2.5. Let $\mathcal{C}$ be an ∞ -category and suppose that the homotopy category $\text{h}\mathcal{C}$ is homotopy filtered; we wish to show that $\mathcal{C}$ is filtered (the reverse implication follows

from Lemma 9.1.2.11). By virtue of Lemma 9.1.2.12, it will suffice to show that for every integer $n \geq 0$, every morphism of simplicial sets $f : \partial\Delta^n \rightarrow \mathcal{C}$ can be extended to a morphism $\bar{f} : (\partial\Delta^n)^\triangleright \rightarrow \mathcal{C}$. For $n = 0$, this follows from our assumption that $\mathbf{h}\mathcal{C}$ is nonempty. We will therefore assume that $n > 0$. By virtue of Lemma 9.1.2.14, we may assume without loss of generality that the restriction $f_- = f|_{\Delta^{n-1}}$ is the constant map taking the value X for some object $X \in \mathcal{C}$. Set $Y = f(n)$ and let $\mathrm{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y) = \{X\} \times_{\mathcal{C}} \mathcal{C}_{/Y}$ denote the right-pinch morphism space of Construction 4.6.5.1, so that we can identify $f|_{\Lambda_n^n}$ with a morphism of simplicial sets $g : \partial\Delta^{n-1} \rightarrow \mathrm{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)$. Invoking assumption $(*_n)$ of Definition 9.1.2.1, we deduce that there exists a morphism $v : Y \rightarrow Z$ in $\mathcal{C}$ for which the composite map

$$\partial\Delta^{n-1} \xrightarrow{g} \mathrm{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y) \hookrightarrow \mathrm{Hom}_{\mathcal{C}}(X, Y) \xrightarrow{[v] \circ} \mathrm{Hom}_{\mathcal{C}}(X, Z)$$

is nullhomotopic. Since the projection map $\mathcal{C}_{/f} \rightarrow \mathcal{C}_{/Y}$ is a trivial Kan fibration (Corollary 4.3.6.14), we can lift g to a morphism $\tilde{g} : \partial\Delta^{n-1} \rightarrow \{X\} \times_{\mathcal{C}} \mathcal{C}_{/f}$. Combining Propositions 5.2.8.7 and 4.6.9.16, we deduce that the diagram of Kan complexes

$$\begin{array}{ccccc} \{X\} \times_{\mathcal{C}} \mathcal{C}_{/Y} & \longleftarrow & \{X\} \times_{\mathcal{C}} \mathcal{C}_{/f} & \longrightarrow & \{X\} \times_{\mathcal{C}} \mathcal{C}_{/Z} \\ \downarrow \iota_{X,Y}^{\mathrm{R}} & & & & \downarrow \iota_{X,Z}^{\mathrm{R}} \\ \mathrm{Hom}_{\mathcal{C}}(X, Y) & \xrightarrow{[v] \circ} & & & \mathrm{Hom}_{\mathcal{C}}(X, Z) \end{array}$$

commutes up to homotopy, where $\iota_{X,Y}^{\mathrm{R}}$ and $\iota_{X,Z}^{\mathrm{R}}$ are the right-pinch inclusion morphisms of Construction 4.6.5.7. Since $\iota_{X,Z}^{\mathrm{R}}$ is a homotopy equivalence (Proposition 4.6.5.10), it follows that the composite map $\partial\Delta^{n-1} \xrightarrow{\tilde{g}} \{X\} \times_{\mathcal{C}} \mathcal{C}_{/f} \rightarrow \{X\} \times_{\mathcal{C}} \mathcal{C}_{/Z}$ is nullhomotopic, and can therefore be extended to an $(n-1)$ -simplex $g' : \Delta^{n-1} \rightarrow \{X\} \times_{\mathcal{C}} \mathcal{C}_{/Z}$ (Variant 3.2.4.12). Unwinding the definitions, we can identify $\tilde{g}$ and g' with morphisms $(\Lambda_n^n)^\triangleright \rightarrow \mathcal{C}$ and $(\Delta^{n-1})^\triangleright \rightarrow \mathcal{C}$, which can be amalgamated to a single morphism $\bar{f} : (\partial\Delta^n)^\triangleright \rightarrow \mathcal{C}$ extending f . $\square$

Exercise 9.1.2.15. Let $\mathcal{C}$ be an ∞ -category and let $n \geq 1$ be an integer. Show that the (hKan-enriched) homotopy category $\mathbf{h}\mathcal{C}$ satisfies condition $(*_n)$ of Definition 9.1.2.1 if and only if $\mathcal{C}$ satisfies condition $(*_n')$ of Lemma 9.1.2.12. 02Q3

9.1.3 Fibrations over Filtered ∞ -Categories

Let $\mathcal{C}$ be a filtered ∞ -category and suppose we are given a diagram $\mathcal{F} : \mathcal{C} \rightarrow \mathcal{S}$ in the ∞ -category of spaces. Our first goal in this section is to show that the colimit $\varinjlim(\mathcal{F})$ is contractible if and only if the ∞ -category of elements $\int_{\mathcal{C}} \mathcal{F}$ is filtered (Corollary 9.1.3.4). Our proof relies on the following elementary observation: 02Q4

05X6 **Lemma 9.1.3.1.** *Let κ be an infinite cardinal, let K be a κ -small simplicial set and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a cocartesian fibration. If $\mathcal{C}$ is κ -filtered, then every diagram $f : K \rightarrow \mathcal{E}$ admits a natural transformation $\beta : f \rightarrow f'$ where $U \circ f'$ is constant: that is, f' is a diagram in the ∞ -category $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$, for some object $C \in \mathcal{C}$.*

Proof. Since $\mathcal{C}$ is κ -filtered, we can choose an object $C \in \mathcal{C}$ and a morphism $\bar{\beta} : (U \circ e) \rightarrow \underline{C}$ in the ∞ -category $\text{Fun}(K, \mathcal{C})$. Using Theorem 5.2.1.1, we can lift $\bar{\beta}$ to a $(U$ -cocartesian) natural transformation $\beta : e \rightarrow e'$, where e' is a diagram in the ∞ -category $\mathcal{E}_C$. $\square$

02Q5 **Theorem 9.1.3.2.** *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a left fibration of ∞ -categories where the ∞ -category $\mathcal{C}$ is filtered. Then $\mathcal{E}$ is filtered if and only if it is weakly contractible.*

Proof. Assume that $\mathcal{E}$ is weakly contractible; we will show that $\mathcal{E}$ is filtered (the converse follows from Proposition 9.1.1.17). Suppose that we are given a diagram $e : K \rightarrow \mathcal{E}$, where K is a finite simplicial set. We wish to show that there exists a natural transformation from e to a constant diagram. Choose a monomorphism $K \hookrightarrow L$, where L is another finite simplicial set which is weakly contractible (for example, we can take $L = K^{\triangleright}$). Let $\text{Ex}^{\infty}(\mathcal{E})$ be the simplicial set given by Construction 3.3.6.1, so that $\text{Ex}^{\infty}(\mathcal{E})$ is a Kan complex (Proposition 3.3.6.9). Let $\rho^{\infty} : \mathcal{E} \rightarrow \text{Ex}^{\infty}(\mathcal{E})$ be the weak homotopy equivalence of Proposition 3.3.6.7. Since $\mathcal{E}$ is weakly contractible, the Kan complex $\text{Ex}^{\infty}(\mathcal{E})$ is contractible. It follows that the composite map $K \xrightarrow{e} \mathcal{E} \xrightarrow{\rho^{\infty}} \text{Ex}^{\infty}(\mathcal{E})$ can be extended to a map $e^+ : L \rightarrow \text{Ex}^{\infty}(\mathcal{E})$. Since the simplicial set L is finite, the morphism $\bar{e}$ factors through $\text{Ex}^m(\mathcal{E})$ for some $m \gg 0$ (see Proposition 3.6.1.9), and therefore corresponds to a diagram $f : \text{Sd}^m(L) \rightarrow \mathcal{E}$ such that $f|_{\text{Sd}^m(K)}$ is given by the composition $\text{Sd}^m(K) \twoheadrightarrow K \xrightarrow{e} \mathcal{E}$. Note that the quotient map $\text{Sd}^m(K) \twoheadrightarrow K$ is universally localizing (Proposition 6.3.6.2) and therefore right cofinal (Corollary 7.2.1.11). We may therefore replace K by $\text{Sd}^m(K)$ and L by $\text{Sd}^m(L)$, and thereby reduce to the case where $m = 0$: that is, the diagram e admits an extension $f : L \rightarrow \mathcal{E}$. Using Lemma 9.1.3.1, we can choose a natural transformation $\beta : f \rightarrow f'$, where $f' : L \rightarrow \mathcal{E}$ factors through the Kan complex $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ for some object $C \in \mathcal{C}$. Since L is weakly contractible, the morphism f' is nullhomotopic (when regarded as a diagram in the Kan complex $\mathcal{E}_C$). We may therefore assume without loss of generality that $f' = \underline{X}$ is the constant diagram associated to some object $X \in \mathcal{E}_C$. Restricting to the simplicial subset $K \subseteq L$, we obtain a natural transformation from $e = f|_K$ to the constant diagram $f'|_K$. $\square$

05X7 **Corollary 9.1.3.3.** *Let κ be an uncountable regular cardinal, let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a left fibration between essentially κ -small ∞ -categories, and let $\text{Tr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C} \rightarrow \mathcal{S}_{<\kappa}$ be a covariant transport representation for U (Definition 5.6.5.1). Suppose that $\mathcal{C}$ is filtered. Then $\mathcal{E}$ is filtered if and only if the colimit $\varinjlim (\text{Tr}_{\mathcal{E}/\mathcal{C}}) \in \mathcal{S}_{<\kappa}$ is contractible.*

Proof. By virtue of Proposition 7.4.3.1, the colimit $\varinjlim (\text{Tr}_{\mathcal{E}/\mathcal{C}})$ is contractible if and only if the ∞ -category $\mathcal{E}$ is weakly contractible. The desired result is therefore a reformulation of

Theorem 9.1.3.2. □

Corollary 9.1.3.4. *Let $\mathcal{C}$ be a small filtered ∞ -category and let $\mathcal{F} : \mathcal{C} \rightarrow \mathcal{S}$ be a $\mathcal{C}$ -indexed diagram of spaces. Then the colimit $\varinjlim(\mathcal{F}) \in \mathcal{S}$ is contractible if and only if the ∞ -category of elements $\int_{\mathcal{C}} \mathcal{F}$ is filtered.* 05X8

Theorem 9.1.3.2 has a counterpart for κ -filtered ∞ -categories. For this, we will need the following general observation:

Lemma 9.1.3.5. *Let κ be an uncountable cardinal and let $e : K \rightarrow X$ be a morphism of simplicial sets, where K is κ -small and X is weakly contractible. Then e factors through a simplicial subset $Y \subseteq X$, where Y is κ -small and weakly contractible.* 05X9

Proof. Without loss of generality, we may assume that κ is regular (and therefore of cofinality $> \aleph_0$). Let $Y_0 \subseteq X$ be the image of e . We will construct Y as the union of an increasing sequence of κ -small simplicial subsets

$$Y_0 \subseteq Y_1 \subseteq Y_2 \subseteq Y_3 \subseteq \cdots$$

Assume that Y_n has been defined for some $n \geq 0$. Since X is weakly contractible, the Kan complex $\mathrm{Ex}^\infty(X)$ is contractible. It follows that the inclusion $\mathrm{Ex}^\infty(Y_n) \hookrightarrow \mathrm{Ex}^\infty(X)$ is nullhomotopic: that is, it admits an extension $f_n : \mathrm{Ex}^\infty(Y_n)^\triangleright \rightarrow \mathrm{Ex}^\infty(X)$. Since $\mathrm{Ex}^\infty(Y_n)^\triangleright$ is κ -small (Corollary 4.7.4.16), we can choose a κ -small simplicial $Y_{n+1} \subseteq X$ containing Y_n such that f_n factors through $\mathrm{Ex}^\infty(Y_{n+1})$. To complete the proof, it will suffice to show that the union $Y = \bigcup_n Y_n$ is weakly contractible, or equivalently that the Kan complex $\mathrm{Ex}^\infty(Y)$ is contractible. This follows from Corollary 3.2.4.15, since $\mathrm{Ex}^\infty(Y)$ is the colimit of a diagram of nullhomotopic maps

$$\mathrm{Ex}^\infty(Y_0) \hookrightarrow \mathrm{Ex}^\infty(Y_1) \hookrightarrow \mathrm{Ex}^\infty(Y_2) \hookrightarrow \cdots$$

□

Variant 9.1.3.6. Let κ be an infinite cardinal and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a left fibration of ∞ -categories, where $\mathcal{C}$ is κ -filtered. Then $\mathcal{E}$ is κ -filtered if and only if it is weakly contractible. 05XA

Remark 9.1.3.7. Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a left fibration of ∞ -categories, where $\mathcal{C}$ is κ -filtered. Then $\mathcal{E}$ is κ -filtered if and only if it is filtered: by virtue of Variant 9.1.3.6 and Theorem 9.1.3.2, both conditions are equivalent to the requirement that $\mathcal{E}$ is weakly contractible. 05XB

Proof of Variant 9.1.3.6. Assume that $\mathcal{E}$ is weakly contractible; we will show that it is κ -filtered (the converse follows from Proposition 9.1.1.17). If $\kappa = \aleph_0$, this follows from Theorem 9.1.3.2. We may therefore assume without loss of generality that κ is uncountable. Fix a diagram $e : K \rightarrow \mathcal{E}$, where K is a κ -small simplicial set; we wish to show that there

exists a natural transformation from e to a constant diagram. Using Lemma 9.1.3.5, we can reduce to the case where K is weakly contractible. Using Lemma 9.1.3.1, we can reduce further to the situation where e factors through the Kan complex $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ for some object $C \in \mathcal{C}$. In this case, our assumption that K is weakly contractible guarantees that e is nullhomotopic (when regarded as a diagram $\mathcal{E}_C$), and therefore isomorphic to a constant diagram (when regarded as a diagram in $\mathcal{E}$). $\square$

We now record another consequence of Lemma 9.1.3.1, which will be useful in §9.1.5.

05XC Proposition 9.1.3.8. *Let κ be an infinite cardinal, let $\mathcal{C}$ be a κ -filtered ∞ -category, and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a cocartesian fibration of ∞ -categories. The following conditions are equivalent:*

- (1) *The ∞ -category $\mathcal{E}$ is κ -filtered.*
- (2) *For every object $C \in \mathcal{C}$ and every diagram $e : K \rightarrow \mathcal{E}_C$, where K is κ -small, there exists an object $Y \in \mathcal{E}$ and a natural transformation from e to the constant diagram $\underline{Y}$ (in the ∞ -category $\text{Fun}(K, \mathcal{E})$).*
- (3) *For every object $C \in \mathcal{C}$ and every diagram $e : K \rightarrow \mathcal{E}_C$, where K is κ -small, there exists a morphism $f : C \rightarrow D$ of $\mathcal{C}$ satisfying the following condition:*
 - (*) *There is an object $Y \in \mathcal{E}_D$ and a natural transformation $\alpha : e \rightarrow \underline{Y}$ (in the ∞ -category $\text{Fun}(K, \mathcal{E})$) such that $U(\alpha)$ is the constant natural transformation $\underline{f} : \underline{C} \rightarrow \underline{D}$ (in the ∞ -category $\text{Fun}(K, \mathcal{C})$).*

05XD Remark 9.1.3.9. In condition (3) of Proposition 9.1.3.8, let $f_! : \mathcal{E}_C \rightarrow \mathcal{E}_D$ be the functor given by covariant transport along f . Then condition (*) is equivalent to either of the following:

- (*)' *There exists an object $Y \in \mathcal{E}_D$ and a natural transformation $\beta : f_! \circ e \rightarrow \underline{Y}$ (in the ∞ -category $\text{Fun}(K, \mathcal{E}_D)$).*
- (*)'' *The diagram $(f_! \circ e) : K \rightarrow \mathcal{E}_D$ admits an extension to $K^{\triangleright}$.*

The equivalence $(*) \Leftrightarrow (*)'$ follows from Remark 5.1.3.8 (applied to the cocartesian fibration $\text{Fun}(K, \mathcal{E}) \rightarrow \text{Fun}(K, \mathcal{C})$), and the equivalence $(*)' \Leftrightarrow (*)''$ from Theorem 4.6.4.19. In the case where U is a left fibration, we can further reformulate conditions (*)'' as follows:

- (*)''' *The diagram $(f_! \circ e) : K \rightarrow \mathcal{E}_D$ is nullhomotopic.*

Proof of Proposition 9.1.3.8. The implications $(1) \Rightarrow (2)$ and $(3) \Rightarrow (2)$ are immediate from the definitions, and the implication $(2) \Rightarrow (1)$ follows from Lemma 9.1.3.1. We will complete the proof by showing that $(2) \Rightarrow (3)$. Let $C \in \mathcal{C}$ be an object and let $e : K \rightarrow \mathcal{E}_C$ be

a diagram, where K is a κ -small simplicial set. It follows from (2) that there exists an object $X \in \mathcal{E}$ and a natural transformation $\beta : e \rightarrow \underline{X}$ in the ∞ -category $\mathrm{Fun}(K, \mathcal{E})$. Set $C' = U(X)$ and form a pushout diagram of simplicial sets

$$\begin{array}{ccc} (\{0\} \times K) \amalg (\{1\} \times K) & \longrightarrow & \{C\} \amalg \{C'\} \\ \downarrow & & \downarrow \\ \Delta^1 \times K & \xrightarrow{q} & L. \end{array}$$

By construction, $U(\beta)$ corresponds to a diagram in $\mathcal{C}$ which factors as a composition

$$\Delta^1 \times K \xrightarrow{q} L \xrightarrow{s} \mathcal{C}.$$

Since L is κ -small and $\mathcal{C}$ is κ -filtered, the diagram s admits an extension $\bar{s} : L^\triangleright \rightarrow \mathcal{C}$. Let $D \in \mathcal{C}$ be the image under $\bar{s}$ of the cone point of $L^\triangleright$. Restricting $\bar{s}$ to the edges $\{C\}^\triangleright \subseteq L^\triangleright$ and $\{C'\}^\triangleright \subseteq L^\triangleright$, we obtain a pair of morphisms $f : C \rightarrow D$ and $g : C' \rightarrow D$. Note that q extends to a morphism $\bar{q} : \Delta^2 \times K \rightarrow L^\triangleright$, carrying $\{2\} \times K$ to the cone point of $L^\triangleright$. Let us identify the composition $\bar{s} \circ \bar{q}$ with a 2-simplex σ of the ∞ -category $\mathrm{Fun}(K, \mathcal{C})$, which we depict as a diagram

$$\begin{array}{ccc} & \underline{C'} & \\ \nearrow & & \searrow \\ \underline{C} & \xrightarrow{\underline{f}} & \underline{D}. \end{array}$$

Since U is a cocartesian fibration, we can write $g = U(\tilde{g})$ for some morphism $\tilde{g} : X \rightarrow Y$ of $\mathcal{E}$. Let $\gamma : \underline{X} \rightarrow \underline{Y}$ denote the image of $\tilde{g}$ under the diagonal map $\mathcal{E} \rightarrow \mathrm{Fun}(K, \mathcal{E})$. Using Corollary 4.1.4.2, we can lift σ to a 2-simplex

$$\begin{array}{ccc} & \underline{X} & \\ \nearrow \beta & & \searrow \gamma \\ e & \xrightarrow{\alpha} & \underline{Y} \end{array}$$

of the ∞ -category $\mathrm{Fun}(K, \mathcal{E})$. By construction, we have $U(\alpha) = \underline{f}$, so the morphism f satisfies condition (*). $\square$

Remark 9.1.3.10. In the situation of Proposition 9.1.3.8, suppose that $\kappa = \aleph_0$. In this case, it suffices to verify conditions (2) and (3) in the special case where K has the form $\partial\Delta^n$, for some integer $n \geq 0$. See Lemma 9.1.2.12. 05XE

05XF **Corollary 9.1.3.11.** *Let κ be an infinite cardinal, let $\mathcal{C}$ be a κ -filtered ∞ -category, and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a cocartesian fibration. Assume that, for each object $C \in \mathcal{C}$, the ∞ -category $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is κ -filtered. Then $\mathcal{E}$ is κ -filtered.*

06CG **Corollary 9.1.3.12.** *Let $\mathcal{C}$ be a filtered ∞ -category and suppose that we are given a collection of cocartesian fibrations $\{U_i : \mathcal{E}_i \rightarrow \mathcal{C}\}_{i \in I}$ indexed by a set I . Assume that each of the ∞ -categories $\mathcal{E}_i$ is filtered and that $\mathcal{C}$ satisfies the following condition:*

()_ For every object $C \in \mathcal{C}$ and every collection of morphisms $\{f_i : C \rightarrow D_i\}_{i \in I}$, there exists a morphism $f : C \rightarrow D$ of $\mathcal{C}$ which factors through each f_i .*

Then the ∞ -category $\mathcal{E} = \mathcal{C} \times_{\text{Fun}(I, \mathcal{C})} (\prod_{i \in I} \mathcal{E}_i)$ is filtered.

05XU **Remark 9.1.3.13.** In the situation of Corollary 9.1.3.12, condition $(*)_I$ asserts that every diagram $I^{\triangleleft} \rightarrow \mathcal{C}$ admits an extension to $(I^{\triangleleft})^{\triangleright}$. This condition is automatically satisfied if $\mathcal{C}$ is κ -filtered for some infinite cardinal κ larger than the cardinality of I . For a converse, see Proposition 9.1.5.10.

Proof of Corollary 9.1.3.12. Let $U : \mathcal{E} \rightarrow \mathcal{C}$ denote the projection onto the first factor. It follows from Remark 5.1.4.7 that U is a cocartesian fibration. We will show that U satisfies condition (3) of Proposition 9.1.3.8. Suppose we are given an object $C \in \mathcal{C}$ and a diagram $e : K \rightarrow \mathcal{E}_C$, where K is a finite simplicial set. For each $i \in I$, our assumption that $\mathcal{E}_i$ is κ -filtered guarantees that we can choose a morphism $f_i : C \rightarrow D_i$ of $\mathcal{C}$ for which the composite diagram

$$K \xrightarrow{e} \{C\} \times_{\mathcal{C}} \mathcal{E} \rightarrow \{C\} \times_{\mathcal{C}} \mathcal{E}_i \xrightarrow{f_i!} \{D_i\} \times_{\mathcal{C}} \mathcal{E}_i$$

admits an extension to $K^{\triangleright}$. Using condition $(*)_I$, we can choose a morphism $f : C \rightarrow D$ of $\mathcal{C}$ which factors through each of the morphisms f_i . Then the diagram

$$K \xrightarrow{e} \{C\} \times_{\mathcal{C}} \mathcal{E} \xrightarrow{f!} \{D\} \times_{\mathcal{C}} \mathcal{E}$$

admits an extension to $K^{\triangleright}$. □

06CH **Corollary 9.1.3.14.** *Let $U_0 : \mathcal{E}_0 \rightarrow \mathcal{C}$ and $U_1 : \mathcal{E}_1 \rightarrow \mathcal{C}$ be cocartesian fibrations of ∞ -categories. If $\mathcal{E}_0$, $\mathcal{E}_1$, and $\mathcal{C}$ are filtered, then the fiber product $\mathcal{E}_0 \times_{\mathcal{C}} \mathcal{E}_1$ is also filtered.*

Proof. Combine Corollary 9.1.3.12 and Remark 9.1.3.13. □

9.1.4 Cofinal Functors of Filtered ∞ -Categories

06CJ Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Recall that F is right cofinal if and only if, for every object $D \in \mathcal{D}$, the ∞ -category $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$ is weakly contractible (Theorem 7.2.3.1). Our first goal in this section is to show that, if the ∞ -categories $\mathcal{C}$ and $\mathcal{D}$ are filtered, then this criterion can be substantially simplified (Theorem 9.1.4.5). We begin by introducing some terminology.

Definition 9.1.4.1. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. We say that F is *weakly right cofinal* if, for every object $D \in \mathcal{D}$, there exists an object $C \in \mathcal{C}$ and a morphism $v : D \rightarrow F(C)$ in the ∞ -category $\mathcal{D}$. 06CK

Example 9.1.4.2. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Then: 06CL

- The functor F is weakly right cofinal if and only if, for each $D \in \mathcal{D}$, the ∞ -category $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$ is nonempty.
- The functor F is right cofinal if and only if, for each $D \in \mathcal{D}$, the ∞ -category $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$ is weakly contractible (Theorem 7.2.3.1).

In particular, if F is right cofinal, then it is weakly right cofinal.

Example 9.1.4.3. Recall that a functor of ∞ -categories $F : \mathcal{C} \rightarrow \mathcal{D}$ is *essentially surjective* if, for every object $D \in \mathcal{D}$, there exists an object $C \in \mathcal{C}$ and an isomorphism $v : D \xrightarrow{\sim} F(C)$ (Definition 4.6.2.12). It follows that every essentially surjective functor is weakly right cofinal. 06CM

Remark 9.1.4.4. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ and $G : \mathcal{D} \rightarrow \mathcal{E}$ be functors of ∞ -categories. If F and G are weakly right cofinal, then the composition $(G \circ F) : \mathcal{C} \rightarrow \mathcal{E}$ is weakly right cofinal. 06CN

Our first main result can be stated as follows:

Theorem 9.1.4.5. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, where $\mathcal{C}$ and $\mathcal{D}$ are filtered. Then F is right cofinal if and only if, for every object $C \in \mathcal{C}$, the induced functor $F_{C/} : \mathcal{C}_{C/} \rightarrow \mathcal{D}_{F(C)/}$ is weakly right cofinal. 06CP

Remark 9.1.4.6. Theorem 9.1.4.5 asserts that a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ between filtered ∞ -categories is right cofinal if and only if, for every object $C \in \mathcal{C}$ and every morphism $u : F(C) \rightarrow D$ in the ∞ -category $\mathcal{D}$, there exists a morphism $w : C \rightarrow C'$ of $\mathcal{C}$ and a 2-simplex 06CQ

$$\begin{array}{ccc}
 & D & \\
 u \nearrow & & \searrow v \\
 F(C) & \xrightarrow{F(w)} & F(C').
 \end{array}$$

of the ∞ -category $\mathcal{D}$. This is equivalent to the requirement that $F([w])$ factors through $[u] : F(C) \rightarrow D$ when regarded as a morphism in the homotopy category $\mathbf{h}\mathcal{D}$. In particular, the condition that F is right cofinal depends only on the induced functor of homotopy categories $\mathbf{h}F : \mathbf{h}\mathcal{C} \rightarrow \mathbf{h}\mathcal{D}$.

06CR **Corollary 9.1.4.7.** *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor between filtered ∞ -categories. Then F is right cofinal if and only if (the nerve of) the functor $hF : h\mathcal{C} \rightarrow h\mathcal{D}$ is right cofinal.*

06CS **Corollary 9.1.4.8.** *Let $\mathcal{C}$ be a filtered ∞ -category. Then the tautological map $\mathcal{C} \rightarrow N_{\bullet}(h\mathcal{C})$ is right cofinal.*

The following is a generalization of Corollary 7.2.3.4:

06CT **Corollary 9.1.4.9.** *Let $\mathcal{C}$ be a filtered ∞ -category, let $(Q, \leq)$ be a directed partially ordered set, and let $F : \mathcal{C} \rightarrow N_{\bullet}(Q)$ be a functor. Then F is right cofinal if and only if it is weakly right cofinal.*

Proof. Assume that F is weakly right cofinal; we will show that F satisfies the criterion of Remark 9.1.4.6, and is therefore right cofinal (the converse follows from Example 9.1.4.2). Fix an object $X \in \mathcal{C}$ and an element $q \in Q$ satisfying $F(X) \leq q$. We wish to show that there exists a morphism $f : X \rightarrow Z$ of $\mathcal{C}$ such that $q \leq F(Z)$. Applying our assumption that F is weakly right cofinal, we can choose an object $Y \in \mathcal{C}$ satisfying $q \leq F(Y)$. We complete the proof by observing that there is another object $Z \in \mathcal{C}$ with morphisms $f : X \rightarrow Z$ and $g : Y \rightarrow Z$, by virtue of our assumption that $\mathcal{C}$ is filtered. $\square$

06CU **Example 9.1.4.10.** Let $(P, \leq)$ and $(Q, \leq)$ be directed partially ordered sets and let $f : P \rightarrow Q$ be a nondecreasing function. Corollary 9.1.4.9 implies that the functor $N_{\bullet}(f) : N_{\bullet}(P) \rightarrow N_{\bullet}(Q)$ is right cofinal if and only if, for each $q \in Q$, there exists $p \in P$ satisfying $q \leq f(p)$.

06CV **Warning 9.1.4.11.** Let $\mathcal{C}$ and $\mathcal{D}$ be filtered ∞ -categories. In general, a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ which is weakly right cofinal need not be right cofinal (Exercise 9.1.4.12). That is, the coslice construction appearing in the formulation of Theorem 9.1.4.5 cannot be omitted.

06CW **Exercise 9.1.4.12.** Let $\mathcal{C}$ be the category described as follows:

- The set of objects $\text{Ob}(\mathcal{C})$ is given by $\{X_n\}_{n \in \mathbf{Z}}$.
- Morphisms in $\mathcal{C}$ are given by

$$\text{Hom}_{\mathcal{C}}(X_m, X_n) = \begin{cases} \{0, 1\} & \text{if } m \leq n \\ \emptyset & \text{otherwise,} \end{cases}$$

with composition given by multiplication on the set $\{0, 1\}$.

Then the diagram

$$\cdots \rightarrow X_{-2} \xrightarrow{1} X_{-1} \xrightarrow{1} X_0 \xrightarrow{1} X_1 \xrightarrow{1} X_2 \xrightarrow{1} \cdots$$

determines a functor of ∞ -categories $F : N_{\bullet}(\mathbf{Z}, \leq) \rightarrow N_{\bullet}(\mathcal{C})$ which is essentially surjective, and therefore weakly right cofinal (Example 9.1.4.3). Show the ∞ -category $N_{\bullet}(\mathcal{C})$ filtered but F is not right cofinal.

We now turn to the proof of Theorem 9.1.4.5. We begin by considering the special case where $F : \mathcal{C} \rightarrow \mathcal{D}$ is a cocartesian fibration of ∞ -categories. Then, for every object $C \in \mathcal{C}$ and every morphism $u : F(C) \rightarrow D$ in the ∞ -category $\mathcal{D}$, we can choose a F -cocartesian morphism $\tilde{u} : C \rightarrow \tilde{D}$ of $\mathcal{C}$ satisfying $F(\tilde{u}) = u$. It follows that the map of coslice ∞ -categories $F_{/C} : \mathcal{C}_{C/} \rightarrow \mathcal{D}_{F(C)/}$ is essentially surjective, and therefore automatically weakly right cofinal (Example 9.1.4.3). In this case, Theorem 9.1.4.5 reduces to the following:

Proposition 9.1.4.13. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a cocartesian fibration of ∞ -categories. If $\mathcal{C}$ and $\mathcal{D}$ are filtered, then F is right cofinal.* 06CX

Proof. For each object $D \in \mathcal{D}$, the ∞ -category $\mathcal{D}_{D/}$ is filtered (Proposition 9.1.1.16) and the projection map $\mathcal{D}_{D/} \rightarrow \mathcal{D}$ is a cocartesian fibration (Proposition 4.3.6.1). Applying Corollary 9.1.3.14, we conclude that the fiber product $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$ is a filtered ∞ -category, and is therefore weakly contractible (Proposition 9.1.1.17). Allowing the object D to vary, we conclude that the functor F is right cofinal (Theorem 7.2.3.1). $\square$

Corollary 9.1.4.14. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a left fibration of ∞ -categories, where the ∞ -category $\mathcal{D}$ is filtered. The following conditions are equivalent:* 06CY

- (1) *The ∞ -category $\mathcal{C}$ is filtered.*
- (2) *The functor F is right cofinal.*
- (3) *The ∞ -category $\mathcal{C}$ is weakly contractible.*

Proof. The equivalence (1) $\Leftrightarrow$ (3) is Theorem 9.1.3.2 and the implication (1) $\Rightarrow$ (2) follows from Corollary 9.1.4.13. The implication (2) $\Rightarrow$ (3) follows from the weak contractibility of the filtered ∞ -category $\mathcal{D}$ (Proposition 9.1.1.17), since every right cofinal functor is a weak homotopy equivalence (Proposition 7.2.1.5). $\square$

Corollary 9.1.4.15. *Let κ be a regular cardinal and let $\mathcal{C}$ be a κ -filtered ∞ -category. For every κ -small diagram $q : K \rightarrow \mathcal{C}$, the forgetful functor $U : \mathcal{C}_{q/} \rightarrow \mathcal{C}$ is right cofinal.* 06CZ

Proof. It follows from Proposition 9.1.1.16 that the coslice ∞ -category $\mathcal{C}_{q/}$ is κ -filtered, so that U is right cofinal by virtue of Corollary 9.1.4.14. $\square$

Corollary 9.1.4.16. *Let $\mathcal{C}$ be a filtered ∞ -category. For every object $C \in \mathcal{C}$, the forgetful functor $\mathcal{C}_{C/} \rightarrow \mathcal{C}$ is right cofinal.* 06D0

Proof. Apply Corollary 9.1.4.15 in the special case $\kappa = \aleph_0$ and $K = \Delta^0$. $\square$

Proposition 9.1.4.17. *Let $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ be filtered ∞ -categories. Suppose we are given functors $F : \mathcal{C} \rightarrow \mathcal{D}$ and $G : \mathcal{D} \rightarrow \mathcal{E}$, where G is a left fibration. Then F is right cofinal if and only if $(G \circ F) : \mathcal{C} \rightarrow \mathcal{E}$ is right cofinal.* 06D1

Proof. Assume that $G \circ F$ is right cofinal; we will prove that F is right cofinal (the converse follows from Proposition 7.2.1.6, since G is right cofinal by virtue of Corollary 9.1.4.14). Note that F factors as a composition

$$\mathcal{C} \xrightarrow{F'} \mathcal{C} \times_{\mathcal{E}} \mathcal{D} \xrightarrow{V} \mathcal{D},$$

where F' is given by the pair of functors $(\mathrm{id}_{\mathcal{C}}, F)$ and V is given by projection onto the second factor. Here V is the pullback of the right cofinal functor $(G \circ F)$ along the left fibration G , and is therefore right cofinal by virtue of Proposition 7.2.3.12. It will therefore suffice to show that F' is right cofinal (Proposition 7.2.1.6).

Note that V is a weak homotopy equivalence (Proposition 7.2.1.5). Since $\mathcal{D}$ is weakly contractible (Proposition 9.1.1.17), it follows that $\mathcal{C} \times_{\mathcal{E}} \mathcal{D}$ is also weakly contractible. Let $G' : \mathcal{C} \times_{\mathcal{E}} \mathcal{D} \rightarrow \mathcal{C}$ be the projection map onto the second factor. Then G' is a pullback of G , and is therefore a left fibration. Applying Corollary 9.1.4.14, we conclude that G' is right cofinal. Since the composition $G' \circ F' = \mathrm{id}_{\mathcal{C}}$ is also right cofinal, Proposition 7.2.1.6 guarantees that F' is right cofinal as desired. $\square$

06D2 Corollary 9.1.4.18. *Let κ be a regular cardinal, let $\mathcal{C}$ and $\mathcal{D}$ be κ -filtered ∞ -categories, and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a right cofinal functor. Then, for every κ -small diagram $q : K \rightarrow \mathcal{C}$, the functor of coslice ∞ -categories $F_{q/} : \mathcal{C}_{q/} \rightarrow \mathcal{D}_{(F \circ q)/}$ is also right cofinal.*

Proof. Let $U : \mathcal{C}_{q/} \rightarrow \mathcal{C}$ and $V : \mathcal{D}_{(F \circ q)/} \rightarrow \mathcal{D}$ be the forgetful functors. Since $\mathcal{C}$ is κ -filtered, the left fibration U is right cofinal (Corollary 9.1.4.15). Applying Proposition 9.1.4.17, we conclude that $F \circ U = V \circ F_{q/}$ is also right cofinal. Since V is also left fibration, Proposition 9.1.4.17 guarantees that $F_{q/}$ is right cofinal. $\square$

06D3 Corollary 9.1.4.19. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a right cofinal functor between filtered ∞ -categories. Then, for every object $C \in \mathcal{C}$, the induced map of coslice ∞ -categories $F_{C/} : \mathcal{C}_{C/} \rightarrow \mathcal{D}_{F(C)/}$ is right cofinal.*

Proof. Apply Corollary 9.1.4.18 in the special case $\kappa = \aleph_0$ and $K = \Delta^0$. $\square$

06D4 Warning 9.1.4.20. In the statement of Corollary 9.1.4.19, the hypothesis that $\mathcal{C}$ is filtered cannot be omitted. For example, let $\mathcal{C}$ denote the ∞ -category given by the left cone $(\partial\Delta^1)^{\triangleleft}$. The inclusion map $\partial\Delta^1 \hookrightarrow \Delta^1$ then extends uniquely to a functor $F : \mathcal{C} \rightarrow \Delta^1$, carrying the cone point of $\mathcal{C}$ to the vertex $0 \in \Delta^1$. The functor F is right cofinal, but the induced map $F_{0/} : \mathcal{C}_{0/} \rightarrow (\Delta^1)_{0/} \simeq \Delta^1$ is not.

Proof of Theorem 9.1.4.5. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor between filtered ∞ -categories. Assume that, for every object $C \in \mathcal{C}$, the functor $F_{C/} : \mathcal{C}_{C/} \rightarrow \mathcal{D}_{F(C)/}$ is weakly right cofinal; we wish to show that F is right cofinal (the converse follows Corollary 9.1.4.19 and Example 9.1.4.2). By virtue of Theorem 7.2.3.1, it will suffice to show that for each object $X \in \mathcal{D}$,

the ∞ -category $\tilde{\mathcal{C}} = \mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{X/}$ is weakly contractible. Let $U : \tilde{\mathcal{C}} \rightarrow \mathcal{C}$ be given by projection onto the first factor. We will complete the proof by showing that the left fibration U satisfies the criterion of Proposition 9.1.3.8, so that $\tilde{\mathcal{C}}$ is filtered. Fix an object $C \in \mathcal{C}$ and a finite diagram $f : K \rightarrow \{C\} \times_{\mathcal{C}} \tilde{\mathcal{C}}$. We wish to show that there is a morphism $w : C \rightarrow C'$ of $\mathcal{C}$ such that the composite map

$$K \xrightarrow{f} \{C\} \times_{\mathcal{C}} \tilde{\mathcal{C}} \xrightarrow{w_!} \{C'\} \times_{\mathcal{C}} \tilde{\mathcal{C}}$$

is nullhomotopic, where $w_!$ is the covariant transport functor associated to the left fibration U . Note that, since the ∞ -category $\mathcal{D}_{X/}$ is filtered (Proposition 9.1.1.16), the analogous condition is satisfied for the left fibration $V : \mathcal{D}_{X/} \rightarrow \mathcal{D}$; that is, we can choose a morphism $u : F(C) \rightarrow D$ in $\mathcal{D}$ for which the composite map

$$K \xrightarrow{f} \{F(C)\} \times_{\mathcal{D}} \mathcal{D}_{X/} \xrightarrow{u_!} \{D\} \times_{\mathcal{D}} \mathcal{D}_{X/}.$$

We now complete the proof by taking $w : C \rightarrow C'$ to be any morphism of $\mathcal{C}$ having the property that $F(w)$ factors through u (the existence of which is guaranteed by our assumption that $F_{C/}$ is weakly right cofinal; see Remark 9.1.4.6). $\square$

9.1.5 Filtered Colimits of Spaces

Our goal in this section is to establish the following characterization of filtered ∞ -categories:

Theorem 9.1.5.1. *Let $\mathcal{C}$ be a small ∞ -category. Then $\mathcal{C}$ is filtered if and only if $\mathcal{C}$ -indexed colimits commute with finite limits in the ∞ -category of spaces $\mathcal{S}$ (see Definition 7.7.7.2).*

Recall that an ∞ -category $\mathcal{C}$ is filtered if and only if, for every finite simplicial set K , the diagonal map $\mathcal{C} \rightarrow \text{Fun}(K, \mathcal{C})$ is right cofinal (Proposition 9.1.1.18). One direction of Theorem 9.1.5.1 is a consequence of the following general result:

Proposition 9.1.5.2. *Let $\mathcal{C}$ be a small ∞ -category and let K be a small simplicial set. If $\mathcal{C}$ -indexed colimits commute with K^{op} -indexed limits in the ∞ -category $\mathcal{S}$, then the diagonal map $\mathcal{C} \rightarrow \text{Fun}(K, \mathcal{C})$ is right cofinal.*

Warning 9.1.5.3. The converse of Proposition 9.1.5.2 is false in general. For example, suppose that $\mathcal{C}$ is the nerve of the linearly ordered set $\{0 < 1 < 2 < \cdots\}$, and let K be a connected Kan complex. Then the diagonal map $\mathcal{C} \rightarrow \text{Fun}(K, \mathcal{C})$ is an isomorphism (in particular, it is right cofinal). But it is generally not true that sequential colimits commute with K^{op} -indexed limits in the ∞ -category $\mathcal{S}$.

Following the convention of Remark 4.7.0.5, we can regard Proposition 9.1.5.2 as a special case of a more precise assertion:

05XP **Variant 9.1.5.4.** Let κ , λ , and μ be infinite cardinals. Assume that κ is uncountable and that μ has cofinality $\geq \kappa$ and exponential cofinality $\geq \lambda$. Let $\mathcal{C}$ be a κ -small ∞ -category and let K be a λ -small simplicial set. If $\mathcal{C}$ -indexed colimits commute with K^{op} -indexed limits in the ∞ -category $\mathcal{S}_{<\mu}$, then the diagonal map $\mathcal{C} \rightarrow \text{Fun}(K, \mathcal{C})$ is right cofinal.

Proof. By virtue of Corollary 7.2.3.9, it will suffice to show that for every diagram $f : K \rightarrow \mathcal{C}$, the coslice ∞ -category $\mathcal{C}_{f/}$ is weakly contractible. Let $h^\bullet : \mathcal{C}^{\text{op}} \rightarrow \text{Fun}(\mathcal{C}, \mathcal{S}_{<\mu})$ be a contravariant Yoneda embedding for $\mathcal{C}$. Since the ∞ -category $\mathcal{S}_{<\mu}$ admits K^{op} -indexed limits, the composite diagram

$$K^{\text{op}} \xrightarrow{f^{\text{op}}} \mathcal{C}^{\text{op}} \xrightarrow{h^\bullet} \text{Fun}(\mathcal{C}, \mathcal{S}_{<\mu})$$

admits a limit $\mathcal{F} \in \text{Fun}(K^{\text{op}}, \mathcal{S}_{<\mu})$. It follows from Corollary 8.4.2.8 that $\mathcal{F}$ is a covariant transport representation for the left fibration $\mathcal{C}_{f/} \rightarrow \mathcal{C}$. Consequently, the ∞ -category $\mathcal{C}_{f/}$ is weakly contractible if and only if the colimit $\varinjlim(\mathcal{F})$ is contractible (Proposition 7.4.3.1). Invoking our assumption that $\mathcal{C}$ -indexed colimits commute with K^{op} -indexed limits, we are reduced to proving that for each vertex $v \in K$, the corepresentable functor $\text{Hom}_{\mathcal{C}}(f(v), \bullet)$ has contractible colimit, which follows from Example 7.4.3.7. $\square$

05XQ **Remark 9.1.5.5.** Let $\mathcal{C}$ be a small ∞ -category and let K be a small simplicial set. It follows from the proof of Variant 9.1.5.4 that the diagonal functor $\mathcal{C} \rightarrow \text{Fun}(K, \mathcal{C})$ is right cofinal if and only if the following condition is satisfied:

($\ast_0$) If $\mathcal{F} \in \text{Fun}(\mathcal{C}, \mathcal{S})$ can be written as an K^{op} -indexed limit of corepresentable functors, then the colimit $\varinjlim(\mathcal{F})$ is contractible.

Compare with condition ($\ast$) of Proposition 7.7.7.3.

05XV **Lemma 9.1.5.6.** *Let $\mathcal{C}$ be a filtered ∞ -category. Suppose we are given left fibrations of ∞ -categories $U : \tilde{\mathcal{C}} \rightarrow \mathcal{C}$, $V_0 : \tilde{\mathcal{C}}_0 \rightarrow \tilde{\mathcal{C}}$, and $V_1 : \tilde{\mathcal{C}}_1 \rightarrow \tilde{\mathcal{C}}$. If $\tilde{\mathcal{C}}$, $\tilde{\mathcal{C}}_0$, and $\tilde{\mathcal{C}}_1$ are weakly contractible, then the fiber product $\tilde{\mathcal{C}}_0 \times_{\tilde{\mathcal{C}}} \tilde{\mathcal{C}}_1$ is also weakly contractible.*

Proof. It follows from Theorem 9.1.3.2 that the ∞ -categories $\tilde{\mathcal{C}}$, $\tilde{\mathcal{C}}_0$, and $\tilde{\mathcal{C}}_1$ are filtered. Applying Corollary 9.1.3.12, we conclude that the ∞ -category $\tilde{\mathcal{C}}_0 \times_{\tilde{\mathcal{C}}} \tilde{\mathcal{C}}_1$ is also filtered, and therefore weakly contractible (Proposition 9.1.1.17). $\square$

Theorem 9.1.5.1 is a consequence of the following more precise result:

05XW **Proposition 9.1.5.7.** *Let $\mathcal{C}$ be an ∞ -category. The following conditions are equivalent:*

- (1) *The ∞ -category $\mathcal{C}$ is filtered.*
- (2) *For every finite simplicial set K , the diagonal map $\mathcal{C} \rightarrow \text{Fun}(K, \mathcal{C})$ is right cofinal.*

- (3) *There exists an uncountable regular cardinal λ such that $\mathcal{C}$ is essentially λ -small and $\mathcal{C}$ -indexed colimits commute with finite limits in the ∞ -category $\mathcal{S}_{<\lambda}$.*
- (4) *For every uncountable regular cardinal λ , if $\mathcal{C}$ is essentially λ -small, then $\mathcal{C}$ -indexed colimits commute with finite limits in the ∞ -category $\mathcal{S}_{<\lambda}$.*

Proof. The implication (4) $\Rightarrow$ (3) is trivial, the implication (3) $\Rightarrow$ (2) follows from Variant 9.1.5.4, and the equivalence (2) $\Leftrightarrow$ (1) is a special case of Proposition 9.1.1.18. We will complete the proof by showing that (1) implies (4). Assume that $\mathcal{C}$ is filtered and fix an uncountable regular cardinal λ such that $\mathcal{C}$ is essentially λ -small; we wish to show that the colimit functor $\varinjlim : \text{Fun}(\mathcal{C}, \mathcal{S}_{<\lambda}) \rightarrow \mathcal{S}_{<\lambda}$ preserves finite limits. We first note that $\varinjlim$ preserves final objects: if $\mathcal{F}$ is a final object of the ∞ -category $\text{Fun}(\mathcal{C}, \mathcal{S}_{<\lambda})$, then the Kan complex $\varinjlim(\mathcal{F})$ is weakly homotopy equivalent to $\mathcal{C}$ (Example 7.1.2.9) and is therefore contractible (Proposition 9.1.1.17). It will therefore suffice to show that the functor $\varinjlim$ preserves pullbacks (Corollary 7.6.2.30). Using Variant 7.7.7.4, we can reformulate this statement as follows:

(*) Suppose we are given a (levelwise) pullback diagram σ :

$$\begin{array}{ccc} \mathcal{F}_{01} & \longrightarrow & \mathcal{F}_0 \\ \downarrow & & \downarrow \\ \mathcal{F}_1 & \longrightarrow & \mathcal{F} \end{array} \quad \begin{array}{l} 05XX \\ (9.1) \end{array}$$

in the ∞ -category $\text{Fun}(\mathcal{C}, \mathcal{S}_{<\lambda})$. If the colimits $\varinjlim(\mathcal{F})$, $\varinjlim(\mathcal{F}_0)$, and $\varinjlim(\mathcal{F}_1)$ are contractible, then the colimit $\varinjlim(\mathcal{F}_{01})$ is also contractible.

Let us identify σ with a functor $\Delta^1 \times \Delta^1 \times \mathcal{C} \rightarrow \mathcal{S}_{<\lambda}$. By virtue of Corollary 5.6.0.6, this functor arises as the covariant transport representation of a left fibration $U : \mathcal{D} \rightarrow \Delta^1 \times \Delta^1 \times \mathcal{C}$ (which is uniquely determined up to equivalence). For $(i, j) \in \Delta^1 \times \Delta^1$, let $\mathcal{D}_{ij}$ denote the fiber product $\{(i, j)\} \times_{\Delta^1 \times \Delta^1} \mathcal{D}$. Then U restricts to a left fibration $U_{ij} : \mathcal{D}_{ij} \rightarrow \mathcal{C}$ with covariant transport representation $\mathcal{F}_{ij}$. The hypotheses of (*) guarantee that the ∞ -categories $\mathcal{D}_{11}$, $\mathcal{D}_{01}$, and $\mathcal{D}_{10}$ are weakly contractible (Proposition 7.4.3.6), and we wish to show that the ∞ -category $\mathcal{D}_{00}$ is also weakly contractible.

For $(i, j) \in \Delta^1 \times \Delta^1$, let K_{ij} denote the full subcategory of $\Delta^1 \times \Delta^1$ spanned by those vertices (i', j') satisfying $i' \geq i$ and $j' \geq j$. Let $\mathcal{E}_{ij}$ denote the fiber product

$$\mathcal{C} \times_{\text{Fun}(K_{ij}, \mathcal{C})} \text{Fun}/_{\Delta^1 \times \Delta^1}(K_{ij} \times \mathcal{C}, \mathcal{E}).$$

The inclusion maps $\{(i, j)\} \hookrightarrow K_{ij}$ are left anodyne (Example 4.3.7.11), and therefore induce trivial Kan fibrations $\mathcal{E}_{ij} \rightarrow \mathcal{D}_{ij}$ (Proposition 4.2.5.4). It follows that the ∞ -categories

$\mathcal{E}_{11}$, $\mathcal{E}_{01}$, and $\mathcal{E}_{10}$ are weakly contractible, and we wish to show that $\mathcal{E}_{00}$ is also weakly contractible. Since U is a left fibration, each of the projection maps $\mathcal{E}_{ij} \rightarrow \mathcal{C}$ is a left fibration (Proposition 4.2.5.1), and the restriction maps

05XY

$$\begin{array}{ccc} \mathcal{E}_{00} & \longrightarrow & \mathcal{E}_{01} \\ \downarrow & & \downarrow \\ \mathcal{E}_{10} & \longrightarrow & \mathcal{E}_{11} \end{array} \quad (9.2)$$

are also left fibrations. Since $\mathcal{C}$ is filtered, Lemma 9.1.5.6 guarantees that the fiber product $\mathcal{E}_{01} \times_{\mathcal{E}_{11}} \mathcal{E}_{10}$ is also weakly contractible. To complete the proof, it will suffice to show that the diagram (9.2) induces an equivalence $\theta : \mathcal{E}_{00} \rightarrow \mathcal{E}_{01} \times_{\mathcal{E}_{11}} \mathcal{E}_{10}$ of left fibrations over $\mathcal{C}$. By Corollary 5.1.7.16, this is equivalent to the requirement that for each object $C \in \mathcal{C}$, θ restricts to a homotopy equivalence of fibers

$$\theta_C : \{C\} \times_{\mathcal{C}} \mathcal{E}_{00} \rightarrow \{C\} \times_{\mathcal{C}} (\mathcal{E}_{01} \times_{\mathcal{E}_{11}} \mathcal{E}_{10}).$$

This is a reformulation of our assumption that (9.1) is a levelwise pullback square (see Proposition 7.4.1.16). $\square$

05XZ **Remark 9.1.5.8.** Let $\mathcal{C}$ be an ∞ -category. It follows from the proof of Proposition 9.1.5.7 that $\mathcal{C}$ is filtered if and only if it is weakly contractible and satisfies the conclusion of Lemma 9.1.5.6.

We now prove an infinitary version of Theorem 9.1.5.1.

05Y0 **Theorem 9.1.5.9.** *Let $\mathcal{C}$ be a small ∞ -category and let κ be a small infinite cardinal. Then $\mathcal{C}$ is κ -filtered if and only if $\mathcal{C}$ -indexed colimits commute with κ -small limits in the ∞ -category of spaces $\mathcal{S}$.*

As above, we can regard Theorem 9.1.5.9 as a consequence of a more general statement:

05Y1 **Proposition 9.1.5.10.** *Let $\mathcal{C}$ be an ∞ -category and let κ be an infinite cardinal. The following conditions are equivalent:*

- (1) *The ∞ -category $\mathcal{C}$ is κ -filtered.*
- (2) *For every κ -small simplicial set K , the diagonal map $\mathcal{C} \rightarrow \mathrm{Fun}(K, \mathcal{C})$ is right cofinal.*
- (3) *There exists an uncountable regular cardinal λ of exponential cofinality $\geq \kappa$ such that $\mathcal{C}$ is essentially λ -small and the colimit functor $\varinjlim : \mathrm{Fun}(\mathcal{C}, \mathcal{S}_{<\lambda}) \rightarrow \mathcal{S}_{<\lambda}$ is κ -continuous.*

- (4) If λ is any uncountable regular cardinal of exponential cofinality $\geq \kappa$ such that $\mathcal{C}$ is essentially λ -small, then the colimit functor $\varinjlim : \text{Fun}(\mathcal{C}, \mathcal{S}_{<\lambda}) \rightarrow \mathcal{S}_{<\lambda}$ is κ -continuous.
- (5) The ∞ -category $\mathcal{C}$ is filtered and satisfies condition $(*_I)$ of Corollary 9.1.3.12, for every κ -small set I .

Proof. As in the proof of Proposition 9.1.5.7, the implications $(4) \Rightarrow (3) \Rightarrow (2) \Leftrightarrow (1)$ follow from Variant 9.1.5.4 and Proposition 9.1.1.18. The implication $(1) \Rightarrow (5)$ follows from Remarks 9.1.1.10 and 9.1.3.13. We will complete the proof by showing that $(5) \Rightarrow (4)$. Assume that condition (5) is satisfied and fix uncountable regular cardinal λ of exponential cofinality $\geq \kappa$ such that $\mathcal{C}$ is essentially λ -small; we wish to show that the colimit functor $\varinjlim : \text{Fun}(\mathcal{C}, \mathcal{S}_{<\lambda}) \rightarrow \text{Fun}(\mathcal{C}, \mathcal{S}_{<\lambda})$ is κ -continuous. Since $\mathcal{C}$ is filtered, the functor $\varinjlim$ preserves finite limits (Proposition 9.1.5.7). It will therefore suffice to show that $\varinjlim$ reserves I -indexed products, for every κ -small set I (Exercise 7.6.6.16). Using Variant 7.7.7.4, we can reformulate this statement as follows:

- (*) Let $\{\mathcal{F}_i : \mathcal{C} \rightarrow \mathcal{S}_{<\lambda}\}_{i \in I}$ be an I -indexed collection of functors from $\mathcal{C}$ to $\mathcal{S}_{<\lambda}$, and let $\mathcal{F} = \prod_{i \in I} \mathcal{F}_i$ be their product. If each colimit $\varinjlim(\mathcal{F}_i)$ is contractible, then $\varinjlim(\mathcal{F})$ is also contractible.

For each $i \in I$, we can assume that $\mathcal{F}_i$ arises as the covariant transport representation of a left fibration $U_i : \mathcal{E}_i \rightarrow \mathcal{C}$. Our assumption that $\varinjlim(\mathcal{F}_i)$ is contractible then guarantees that the ∞ -category $\mathcal{E}_i$ is weakly contractible (Proposition 7.4.3.6) and therefore filtered (Theorem 9.1.3.2). Applying Corollary 9.1.3.12, we conclude that the ∞ -category $\mathcal{E} = \mathcal{C} \times_{\text{Fun}(I, \mathcal{C})} (\prod_{i \in I} \mathcal{E}_i)$ is also filtered, and therefore weakly contractible (Proposition 9.1.1.17). Since $\mathcal{F}$ is a covariant transport representation for the projection map $U : \mathcal{E} \rightarrow \mathcal{C}$, this is equivalent to the contractibility of $\varinjlim(\mathcal{F})$ (Proposition 7.4.3.6). $\square$

Remark 9.1.5.11. Let $\mathcal{C}$ be a filtered ∞ -category. For every set I , condition $(*_I)$ of Corollary 9.1.3.12 depends only on the homotopy category $\text{h}\mathcal{C}$. Applying Proposition 9.1.5.10, we deduce that $\mathcal{C}$ is κ -filtered if and only if the homotopy category $\text{h}\mathcal{C}$ is κ -filtered. 05Y3

Corollary 9.1.5.12. Let $\mathcal{C}$ be an ∞ -category and let κ be a singular cardinal. Then $\mathcal{C}$ is κ -filtered if and only if it is κ^+ -filtered. 05Y2

Proof. Fix an uncountable regular cardinal λ of exponential cofinality $\geq \kappa^+$ such that $\mathcal{C}$ is essentially λ -small. It follows from Proposition 9.1.5.10 that the colimit functor $\varinjlim : \text{Fun}(\mathcal{C}, \mathcal{S}_{<\lambda}) \rightarrow \mathcal{S}_{<\lambda}$ is κ -continuous, and we wish to show that it is κ^+ -continuous. By virtue of Corollary 7.6.6.16, it will suffice to show that if I is set of cardinality κ , then $\varinjlim$ preserves I -indexed products. Our assumption that κ is singular guarantees that we can decompose I as a disjoint union $\coprod_{j \in J} I_j$, where J is κ -small and each I_j is κ -small. The desired result now follows from Corollary 7.6.1.22. $\square$

0619 Corollary 9.1.5.13. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories and let κ be an infinite cardinal. If $\mathcal{C}$ is κ -filtered and F is right cofinal, then $\mathcal{D}$ is also κ -filtered.*

Proof. Let λ be a regular cardinal of exponential cofinality $\geq \kappa$ such that $\mathcal{C}$ and $\mathcal{D}$ are essentially λ -small. It follows from Proposition 9.1.5.10 (together with Proposition 7.7.7.1) that $\mathcal{D}$ is κ -filtered if and only if, for every κ -small simplicial set K , the limit functor $\varprojlim : \text{Fun}(K, \mathcal{S}_{<\lambda}) \rightarrow \mathcal{S}_{<\lambda}$ preserves $\mathcal{D}$ -indexed colimits. Since F is right cofinal, it will suffice to show that $\varprojlim$ preserves $\mathcal{C}$ -indexed colimits (Corollary 7.2.2.8), which follows from our assumption that $\mathcal{C}$ is κ -filtered. $\square$

06D6 Corollary 9.1.5.14. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a left fibration of ∞ -categories. Any two of the following conditions imply the third:*

- *The ∞ -category $\mathcal{C}$ is filtered.*
- *The ∞ -category $\mathcal{D}$ is filtered.*
- *The functor F is right cofinal.*

Proof. Combine Corollaries 9.1.4.14 and 9.1.5.13. $\square$

061A Corollary 9.1.5.15. *Let κ be an infinite cardinal and let $\mathcal{C}$ be a κ -filtered ∞ -category. Then, for any collection of morphisms W of $\mathcal{C}$, the localization $\mathcal{C}[W^{-1}]$ is κ -filtered.*

Proof. Let $F : \mathcal{C} \rightarrow \mathcal{C}[W^{-1}]$ be a functor which exhibits $\mathcal{C}[W^{-1}]$ as a localization of $\mathcal{C}$ with respect to W (Definition 6.3.1.9). Since F is right cofinal (Proposition 7.2.1.10), Corollary 9.1.5.13 guarantees that $\mathcal{C}[W^{-1}]$ is a κ -filtered ∞ -category. $\square$

061B Corollary 9.1.5.16. *Let κ be an infinite cardinal and let $\mathcal{C}$ be a small κ -filtered ∞ -category. Suppose we are given a diagram $\mathcal{F} : \mathcal{C} \rightarrow \mathcal{QC}$ which carries each object $C \in \mathcal{C}$ to a κ -filtered ∞ -category $\mathcal{F}(C)$. Then the colimit $\varinjlim(\mathcal{F})$ is also a κ -filtered ∞ -category.*

Proof. Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a cocartesian fibration with covariant transport representation $\mathcal{F}$. It follows from Corollary 9.1.3.11 that $\mathcal{E}$ is a κ -filtered ∞ -category. Let W be the collection of all U -cocartesian morphisms of $\mathcal{E}$. By virtue of Proposition 7.4.5.1, the colimit $\varinjlim(\mathcal{F})$ can be identified with the localization $\mathcal{E}[W^{-1}]$, which is κ -filtered by virtue of Corollary 9.1.5.15. $\square$

06D7 Corollary 9.1.5.17. *Let κ be an infinite cardinal, let $\mathcal{D}$ be an ∞ -category, and let $\mathcal{C} \subseteq \mathcal{D}$ be a nonempty full subcategory. Assume that, for every object $C \in \mathcal{C}$ and every morphism $f : C \rightarrow D$ in $\mathcal{D}$, the object D also belongs to $\mathcal{C}$. Then $\mathcal{D}$ is κ -filtered if and only if $\mathcal{C}$ is κ -filtered and the inclusion $\iota : \mathcal{C} \hookrightarrow \mathcal{D}$ is right cofinal.*

Proof. Assume that $\mathcal{D}$ is κ -filtered; we will show that $\mathcal{C}$ is κ -filtered and that ι is right cofinal (the reverse implication is a special case of Corollary 9.1.5.13). We first show that $\mathcal{C}$ is κ -filtered. Let K be a κ -small simplicial set and let $f : K \rightarrow \mathcal{C}$ be a diagram; we wish to show that f can be extended to a map $\bar{f} : K^\triangleright \rightarrow \mathcal{C}$. If $K = \emptyset$, this follows from our assumption that $\mathcal{C}$ is nonempty. Otherwise, our assumption that $\mathcal{D}$ is κ -filtered guarantees that we can extend f to a diagram $\bar{f} : K^\triangleright \rightarrow \mathcal{D}$, which automatically factors through the full subcategory $\mathcal{C} \subseteq \mathcal{D}$.

To complete the proof, we must show that ι is right cofinal. Using the criterion of Theorem 9.1.4.5, we are reduced to showing that for each object $C \in \mathcal{C}$, the functor $\iota_{C/} : \mathcal{C}_{C/} \hookrightarrow \mathcal{D}_{C/}$ is weakly right cofinal. This is clear: our assumption on $\mathcal{C}$ guarantees that $\iota_{C/}$ is an isomorphism. $\square$

Corollary 9.1.5.16 admits the following partial converse:

Proposition 9.1.5.18. *Let $\mathcal{C}$ be a small ∞ -category and let κ be a small infinite cardinal. 02QC The following conditions are equivalent:*

- (1) *The ∞ -category $\mathcal{C}$ is κ -filtered.*
- (2) *The ∞ -category $\mathcal{C}$ can be realized as the colimit of a small diagram $\mathcal{F} : \mathcal{K} \rightarrow \mathcal{QC}$, where $\mathcal{K}$ is κ -filtered and each of the ∞ -categories $\mathcal{F}(k)$ is κ -filtered.*
- (3) *The ∞ -category $\mathcal{C}$ can be realized as the colimit of a small diagram $\mathcal{F} : \mathcal{K} \rightarrow \mathcal{QC}$, where the ∞ -category $\mathcal{K}$ is κ -filtered and each of the ∞ -categories $\mathcal{F}(k)$ has a final object.*

Proof. For any (small) ∞ -category $\mathcal{C}$, the evaluation functor $\text{ev}_1 : \text{Fun}(\Delta^1, \mathcal{C}) \rightarrow \mathcal{C}$ is a cocartesian fibration, whose covariant transport representation

$$\mathcal{C} \rightarrow \mathcal{QC} \quad C \mapsto \mathcal{C} \tilde{\times}_C \{C\}$$

carries each $C \in \mathcal{C}$ to an ∞ -category containing a final object (Proposition 4.6.7.23). Moreover, the ∞ -category $\mathcal{C}$ is a colimit of this diagram (Example 7.4.5.7). This proves the implication (1) $\Rightarrow$ (3). The implication (2) $\Rightarrow$ (1) from Corollary 9.1.5.16 and the implication (3) $\Rightarrow$ (2) from Example 9.1.1.6. $\square$

Remark 9.1.5.19. The proof of Proposition 9.1.5.18 shows that every κ -filtered ∞ -category 061C $\mathcal{C}$ admits a (canonical) presentation as the colimit of a κ -filtered diagram

$$\mathcal{K} \rightarrow \mathcal{QC} \quad (k \in \mathcal{K}) \mapsto \mathcal{C}_k,$$

where each of the ∞ -categories $\mathcal{C}_k$ admits a final object. In §9.1.8, we will prove a more refined version of this statement:

- We can arrange that $\mathcal{K}$ is (the nerve of) a κ -directed partially ordered set.
- We can arrange that each of the ∞ -categories $\mathcal{C}_k$ has the form $\mathcal{D}^{\triangleright}$, for some ∞ -category $\mathcal{D}$.
- The sizes of the ∞ -category $\mathcal{K}$ and $\mathcal{C}_k$ can be controlled in terms of the size of $\mathcal{C}$.

See Proposition 9.1.8.5. Beware that this more refined presentation is not canonical.

9.1.6 Filtered Colimits of Simplicial Sets

03DD Let $\mathcal{C}$ be a small filtered category, let $\mathcal{F} : \mathcal{C} \rightarrow \mathbf{Set}_\Delta$ be a diagram, and let $\mathcal{E} = \varinjlim(\mathcal{F})$ denote the colimit of $\mathcal{F}$ in the category of simplicial sets. If each of the simplicial sets $\mathcal{F}(C)$ is an ∞ -category, then the simplicial set $\mathcal{E}$ is also an ∞ -category (Remark 1.4.0.9). Our goal in this section is to show that, in this case, we can also regard $\mathcal{E}$ as a colimit of the diagram $N_\bullet^{\mathrm{hc}}(\mathcal{F}) : N_\bullet(\mathcal{C}) \rightarrow \mathcal{QC}$. This is a consequence of the following more general result:

03DE **Proposition 9.1.6.1.** *Let $\mathcal{C}$ be a small filtered category and let $\overline{\mathcal{F}} : \mathcal{C}^\triangleright \rightarrow \mathbf{Set}_\Delta$ be a colimit diagram in the category of simplicial sets. Then $\overline{\mathcal{F}}$ is a categorical colimit diagram (see Definition 7.5.8.2).*

03DF **Remark 9.1.6.2.** Let $\mathcal{F} : \mathcal{C} \rightarrow \mathbf{Set}_\Delta$ be a diagram of simplicial sets and let W denote the collection of horizontal edges of the homotopy colimit $\varinjlim(\mathcal{F})$. Proposition 9.1.6.1 asserts that, if the category $\mathcal{C}$ is filtered, then the comparison map $\theta : \varinjlim(\mathcal{F}) \rightarrow \varinjlim(\mathcal{F})$ exhibits $\varinjlim(\mathcal{F})$ as a localization of $\varinjlim(\mathcal{F})$ with respect to W . In particular, θ is a weak homotopy equivalence.

Before giving the proof of Proposition 9.1.6.1, let us record some consequences.

03DG **Corollary 9.1.6.3.** *The inclusion functor $\iota : N_\bullet(\mathbf{QCat}) \hookrightarrow N_\bullet^{\mathrm{hc}}(\mathbf{QCat}) = \mathcal{QC}$ preserves colimits indexed by small filtered categories.*

Proof. Let $\mathcal{C}$ be a small filtered category and suppose we are given a colimit diagram $\overline{\mathcal{F}} : \mathcal{C}^\triangleright \rightarrow \mathbf{QCat}$ in the ordinary category $\mathbf{QCat}$. We wish to show that the induced map $N_\bullet^{\mathrm{hc}}(\overline{\mathcal{F}}) : N_\bullet(\mathcal{C}) \rightarrow \mathcal{QC}$ is a colimit diagram in the ∞ -category $\mathcal{QC}$. By virtue of Corollary 7.5.8.9, this is equivalent to the requirement that $\overline{\mathcal{F}}$ is a categorical colimit diagram, which follows from Proposition 9.1.6.1. $\square$

03DH **Variant 9.1.6.4.** The inclusion functor $N_\bullet(\mathbf{Kan}) \hookrightarrow N_\bullet^{\mathrm{hc}}(\mathbf{Kan}) = \mathcal{S}$ preserves colimits indexed by small filtered categories.

061D **Remark 9.1.6.5.** We will see later that Corollary 9.1.6.3 and Variant 9.1.6.4 imply the *a priori* stronger assertion that the functors

$$N_\bullet(\mathbf{QCat}) \hookrightarrow \mathcal{QC} \quad N_\bullet(\mathbf{Kan}) \hookrightarrow \mathcal{S}$$

preserve colimits indexed by small filtered ∞ -categories (see Examples 9.2.2.20 and 9.2.2.18).

Corollary 9.1.6.6. *Let $\mathcal{C}$ be a small filtered category and let $\mathcal{F} : \mathcal{C} \rightarrow \mathbf{Set}_\Delta$ be a diagram of simplicial sets having colimit $K = \varinjlim(\mathcal{F})$. Let $\mathcal{D}$ be an ∞ -category which admits $N_\bullet(\mathcal{C})$ -indexed colimits and which admits $\mathcal{F}(C)$ -indexed colimits, for each $C \in \mathcal{C}$. Then $\mathcal{D}$ also admits K -indexed colimits. Moreover, if $G : \mathcal{D} \rightarrow \mathcal{E}$ is a functor which preserves both $N_\bullet(\mathcal{C})$ -indexed colimits and $\mathcal{F}(C)$ -indexed colimits for each $C \in \mathcal{C}$, then G also preserves K -indexed colimits.*

Proof. Combine Proposition 9.1.6.1 with Corollary 7.5.8.13. $\square$

Our proof of Proposition 9.1.6.1 will require a brief digression. Let $\mathcal{C}$ be a small category and let $\mathcal{G} : \mathcal{C} \rightarrow \mathbf{Set}_\Delta$ be a diagram of simplicial sets. In §7.5.6, we showed that there exists a projectively cofibrant diagram $\mathcal{F} : \mathcal{C} \rightarrow \mathbf{Set}_\Delta$ equipped with a levelwise weak homotopy equivalence $\alpha : \mathcal{F} \rightarrow \mathcal{G}$ (Proposition 7.5.6.9). Using a somewhat less explicit construction, we can obtain a better approximation to $\mathcal{G}$:

Proposition 9.1.6.7. *Let $\mathcal{C}$ be a small category and let $\mathcal{G} : \mathcal{C} \rightarrow \mathbf{Set}_\Delta$ be a diagram of simplicial sets. Then there exists a projectively cofibrant diagram $\mathcal{F} : \mathcal{C} \rightarrow \mathbf{Set}_\Delta$ and a levelwise trivial Kan fibration $\alpha : \mathcal{F} \rightarrow \mathcal{G}$.*

Proof of Proposition 9.1.6.1 from Proposition 9.1.6.7. Let $\mathcal{C}$ be a small filtered category and let $\overline{\mathcal{F}} : \mathcal{C}^\triangleright \rightarrow \mathbf{Set}_\Delta$ be a colimit diagram in the category of simplicial sets; we wish to show that $\overline{\mathcal{F}}$ is a categorical colimit diagram. Set $\mathcal{F} = \overline{\mathcal{F}}|_{\mathcal{C}}$. Using Proposition 9.1.6.7, we can choose a levelwise categorical equivalence $\alpha : \mathcal{E} \rightarrow \mathcal{F}$, where $\mathcal{E} : \mathcal{C} \rightarrow \mathbf{Set}_\Delta$ is projectively cofibrant. Let $\overline{\mathcal{E}} : \mathcal{C}^\triangleright \rightarrow \mathbf{Set}_\Delta$ be a colimit diagram extending $\mathcal{E}$, so that α extends uniquely to a natural transformation $\overline{\alpha} : \overline{\mathcal{E}} \rightarrow \overline{\mathcal{F}}$. Applying Corollary 4.5.7.2, we deduce that $\overline{\alpha}$ is also a levelwise categorical equivalence. Consequently, to show that $\overline{\mathcal{F}}$ is a categorical colimit diagram, it will suffice to show that $\overline{\mathcal{E}}$ is a categorical colimit diagram (Corollary 7.5.8.6). This follows from Corollary 7.5.8.7, since $\mathcal{E}$ is projectively cofibrant. $\square$

It will be useful to formulate a slightly stronger version of Proposition 9.1.6.7. First, we need some terminology.

Definition 9.1.6.8. Let $\mathcal{C}$ be a small category and let $\alpha : \mathcal{F}' \rightarrow \mathcal{F}$ be a natural transformation between diagrams $\mathcal{F}, \mathcal{F}' : \mathcal{C} \rightarrow \mathbf{Set}_\Delta$. We say that α is a *projective cofibration* if it is left semiorthogonal to all levelwise trivial Kan fibrations (see Remark 4.5.6.2). That is, α is a projective cofibration if every lifting problem

$$\begin{array}{ccc}
 \mathcal{F}' & \xrightarrow{\quad} & \mathcal{G}' \\
 \downarrow \alpha & \nearrow & \downarrow \beta \\
 \mathcal{F} & \xrightarrow{\quad} & \mathcal{G}
 \end{array}$$

admits a solution, under the assumption that β is a levelwise trivial Kan fibration between diagrams $\mathcal{G}, \mathcal{G}' : \mathcal{C} \rightarrow \mathbf{Set}_\Delta$.

03DN Example 9.1.6.9. Let $\mathcal{C}$ be a small category. Then a diagram of simplicial sets $\mathcal{F} : \mathcal{C} \rightarrow \mathbf{Set}_\Delta$ is projectively cofibrant (in the sense of Definition 7.5.6.1) if and only if the unique natural transformation $\emptyset \rightarrow \mathcal{F}$ is a projective cofibration (in the sense of Definition 9.1.6.8). Here $\emptyset : \mathcal{C} \rightarrow \mathbf{Set}_\Delta$ denotes the initial object of the category $\mathbf{Fun}(\mathcal{C}, \mathbf{Set}_\Delta)$, which carries every object of $\mathcal{C}$ to the empty simplicial set.

03DP Example 9.1.6.10. Let $\mathcal{C}$ be a small category. For each object $C \in \mathcal{C}$, let $h^C : \mathcal{C} \rightarrow \mathbf{Set}$ denote the functor corepresented by C (given on objects by the formula $h^C(D) = \mathrm{Hom}_{\mathcal{C}}(C, D)$). If $A \hookrightarrow B$ is a monomorphism of simplicial sets, then the natural transformation $\underline{A} \times h^C \hookrightarrow \underline{B} \times h^C$ is a projective cofibration in $\mathbf{Fun}(\mathcal{C}, \mathbf{Set}_\Delta)$; here $\underline{A}$ and $\underline{B}$ denote the constant simplicial sets taking the values A and B , respectively.

03DQ Remark 9.1.6.11. Let $\mathcal{C}$ be a small category. Then the collection of projective cofibrations in $\mathbf{Fun}(\mathcal{C}, \mathbf{Set}_\Delta)$ is weakly saturated, in the sense of Definition 1.5.4.13. That is, it is closed under retracts, pushouts, and transfinite composition. See Proposition 1.5.4.14.

03DR Proposition 9.1.6.12. Let $\mathcal{C}$ be a small category and let $\alpha_0 : \mathcal{F}_0 \rightarrow \mathcal{G}$ be a natural transformation between diagrams $\mathcal{F}_0, \mathcal{G} : \mathcal{C} \rightarrow \mathbf{Set}_\Delta$. Then α_0 factors as a composition

$$\mathcal{F}_0 \xrightarrow{\beta} \mathcal{F} \xrightarrow{\alpha} \mathcal{G},$$

where β is a projective cofibration and α is a levelwise trivial Kan fibration.

Proof. We will construct $\mathcal{F}$ as the colimit of a diagram of projective cofibrations

$$\mathcal{F}_0 \rightarrow \mathcal{F}_1 \rightarrow \mathcal{F}_2 \rightarrow \mathcal{F}_3 \rightarrow \cdots$$

in the category $\mathbf{Fun}(\mathcal{C}, \mathbf{Set}_\Delta)_{/\mathcal{G}}$. Fix $n \geq 0$, and suppose that we have constructed an object $\mathcal{F}_n \in \mathbf{Fun}(\mathcal{C}, \mathbf{Set}_\Delta)_{/\mathcal{G}}$, which we identify with a natural transformation $\alpha_n : \mathcal{F}_n \rightarrow \mathcal{G}$. For each object $C \in \mathcal{C}$, Exercise 3.1.7.11 guarantees that $\alpha_{n,C}$ factors as a composition

$$\mathcal{F}_n(C) \xrightarrow{\alpha'_{n,C}} \mathcal{F}'_n(C) \xrightarrow{\alpha''_{n,C}} \mathcal{G}(C),$$

where $\alpha'_{n,C}$ is a monomorphism and $\alpha''_{n,C}$ is a trivial Kan fibration (beware that $\mathcal{F}'_n(C)$ does not depend functorially on C). Form a pushout diagram

$$\begin{array}{ccc} \coprod_{C \in \mathcal{C}} \underline{\mathcal{F}_n(C)} \times h^C & \longrightarrow & \coprod_{C \in \mathcal{C}} \underline{\mathcal{F}'_n(C)} \times h^C \\ \downarrow & & \downarrow \\ \mathcal{F}_n & \longrightarrow & \mathcal{F}_{n+1} \end{array}$$

in the category $\text{Fun}(\mathcal{C}, \text{Set}_\Delta)_{/\mathcal{G}}$, where the upper horizontal map is the coproduct of the projective cofibrations described in Example 9.1.6.10. Using Remark 9.1.6.11, we see that each of the maps

$$\mathcal{F}_0 \rightarrow \mathcal{F}_1 \rightarrow \mathcal{F}_2 \rightarrow \mathcal{F}_3 \rightarrow \cdots$$

is a projective cofibration. Setting $\mathcal{F} = \varinjlim_n \mathcal{F}_n$, we obtain a factorization of α_0 as a composition $\mathcal{F}_0 \xrightarrow{\beta} \mathcal{F} \xrightarrow{\alpha} \mathcal{G}$, where β is a projective cofibration. We complete the proof by observing that for each object $C \in \mathcal{C}$, the morphism $\alpha_C : \mathcal{F}(C) \rightarrow \mathcal{G}(C)$ is a trivial Kan fibration, since it can be written as a filtered colimit (in the arrow category $\text{Fun}([1], \text{Set}_\Delta)$) of the trivial cofibrations $\alpha''_{n,C} : \mathcal{F}'_n(C) \rightarrow \mathcal{G}(C)$ (see Remark 1.5.5.3). $\square$

Proof of Proposition 9.1.6.7. Apply Proposition 9.1.6.12 in the special case $\mathcal{F}_0 = \emptyset$ (see Example 9.1.6.9). $\square$

Corollary 9.1.6.13. *Let $\mathcal{C}$ be a small category, and let S be the collection of all projective cofibrations in the category $\text{Fun}(\mathcal{C}, \text{Set}_\Delta)$. Then S is the smallest weakly saturated collection of morphisms which contains each of the inclusion maps $\iota_{n,C} : \underline{\partial\Delta}^n \times h^C \hookrightarrow \underline{\Delta}^n \times h^C$, for each $n \geq 0$ and each object $C \in \mathcal{C}$.* 03DS

Proof. It follows from Remark 9.1.6.11 that S is weakly saturated. Let S' be the smallest weakly saturated collection of morphisms of $\text{Fun}(\mathcal{C}, \text{Set}_\Delta)$ which contains each $\iota_{n,C}$. Using Example 9.1.6.10, we see that S' is contained in S . For every monomorphism of simplicial sets $A \hookrightarrow B$ and every object $C \in \mathcal{C}$, Proposition 1.5.5.14 guarantees that the projective cofibration $\underline{A} \times h^C \hookrightarrow \underline{B} \times h^C$ is contained in S' . It follows from the proof of Proposition 9.1.6.12 that every morphism $\alpha_0 : \mathcal{F}_0 \rightarrow \mathcal{G}$ in $\text{Fun}(\mathcal{C}, \text{Set}_\Delta)$ factors as a composition $\mathcal{F}_0 \xrightarrow{\beta} \mathcal{F} \xrightarrow{\alpha} \mathcal{G}$, where β belongs to S' and α is a trivial Kan fibration. If α_0 is projective cofibration, then the lifting problem

$$\begin{array}{ccc} \mathcal{F}_0 & \xrightarrow{\beta} & \mathcal{F} \\ \downarrow \alpha_0 & \nearrow \text{dashed} & \downarrow \alpha \\ \mathcal{G} & \xlongequal{\quad} & \mathcal{G} \end{array}$$

admits a solution. It follows that α_0 is a retract of the morphism β , and therefore belongs to S' . $\square$

9.1.7 Approximation by Simplicial Subsets

Let $\mathcal{C}$ be a simplicial set. Recall that $\mathcal{C}$ can always be realized as the colimit of a filtered diagram $\{\mathcal{C}_\alpha\}$ of finite simplicial sets: for example, the diagram of all finite simplicial subsets 061E

of itself (Remark 3.6.1.8). Beware that, if $\mathcal{C}$ is an ∞ -category, then we generally cannot arrange that the finite simplicial sets $\mathcal{C}_\alpha$ are ∞ -categories. However, for less restrictive size conditions, this issue does not arise:

061F Proposition 9.1.7.1. *Let λ be an uncountable cardinal, let $\mathcal{C}$ be an ∞ -category, and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a λ -small simplicial subset. Then $\mathcal{C}_0$ is contained in a λ -small simplicial subset $\mathcal{C}' \subseteq \mathcal{C}$ which is an ∞ -category.*

Proof. Without loss of generality, we may assume that λ is regular (Remark 4.7.4.7), and therefore of uncountable cofinality. We will construct $\mathcal{C}'$ as the union of a sequence

$$\mathcal{C}_0 \subseteq \mathcal{C}_1 \subseteq \mathcal{C}_2 \subseteq \mathcal{C}_3 \subseteq \cdots$$

consisting of λ -small simplicial subsets of $\mathcal{C}$. Fix an integer $n \geq 0$, and assume that $\mathcal{C}_n$ has been constructed. Let $\{\sigma_\alpha : \Lambda_i^m \rightarrow \mathcal{C}_n\}_{\alpha \in A}$ be the collection of all inner horns in the simplicial set $\mathcal{C}_n$ (so that $0 < i < m$). Since the simplicial set $\mathcal{C}_n$ is λ -small, the set A is also λ -small (Proposition 4.7.4.10). Since $\mathcal{C}$ is an ∞ -category, each σ_α can be extended to a simplex $\bar{\sigma}_\alpha : \Delta^m \rightarrow \mathcal{C}$. We then choose $\mathcal{C}_{n+1}$ to be any λ -small simplicial subset of $\mathcal{C}$ which contains $\mathcal{C}_n$ and each of the simplices $\bar{\sigma}_\alpha$. It follows immediately from the construction that $\mathcal{C}' = \bigcup_n \mathcal{C}_n$ is a λ -small ∞ -category containing $\mathcal{C}_0$. $\square$

061G Corollary 9.1.7.2. *Let λ be an uncountable regular cardinal. Then every ∞ -category $\mathcal{C}$ can be realized as the colimit of some diagram*

$$A \rightarrow \mathbf{Set}_\Delta \quad (\alpha \in A) \mapsto \mathcal{C}_\alpha,$$

where $(A, \leq)$ is a λ -directed partially ordered set and each $\mathcal{C}_\alpha$ is a λ -small ∞ -category. Moreover, $\mathcal{C}$ is also a colimit of the diagram $\{\mathcal{C}_\alpha\}_{\alpha \in A}$ in the ∞ -category $\mathcal{QC}$.

Proof. Let $\{\mathcal{C}_\alpha\}_{\alpha \in A}$ be the collection of all λ -small simplicial subsets of $\mathcal{C}$ which are ∞ -categories. It follows from Proposition 9.1.7.1 that the index set A is λ -directed (where we write $\alpha \leq \beta$ if $\mathcal{C}_\alpha$ is contained in $\mathcal{C}_\beta$), and that the canonical map $\varinjlim_{\alpha \in A} \mathcal{C}_\alpha \rightarrow \mathcal{C}$ is an isomorphism. The final assertion follows from Corollary 9.1.6.3. $\square$

Proposition 9.1.7.1 has a counterpart for filtered ∞ -categories.

061H Proposition 9.1.7.3. *Let λ be an uncountable cardinal, let $\mathcal{C}$ be a filtered ∞ -category, and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a λ -small simplicial subset. Then $\mathcal{C}_0$ is contained in a λ -small simplicial subset $\mathcal{C}' \subseteq \mathcal{C}$ which is a filtered ∞ -category.*

Proof. Without loss of generality, we may assume that λ is regular (Remark 4.7.4.7), and therefore of uncountable cofinality. As in the proof of Proposition 9.1.7.1, we will construct $\mathcal{C}'$ as the union of an increasing sequence

$$\mathcal{C}_0 \subseteq \mathcal{C}_1 \subseteq \mathcal{C}_2 \subseteq \mathcal{C}_3 \subseteq \cdots,$$

of λ -small simplicial subsets of $\mathcal{C}$, where every inner horn in $\mathcal{C}_n$ extends to a simplex of $\mathcal{C}_{n+1}$. To guarantee that $\mathcal{C}'$ is a filtered ∞ -category, it will suffice to ensure that the following additional condition is satisfied (see Lemma 9.1.2.12):

- For $m, n \geq 0$, every morphism of simplicial sets $f : \partial\Delta^m \rightarrow \mathcal{C}_n$ admits an extension $\bar{f} : (\partial\Delta^m)^\triangleright \rightarrow \mathcal{C}_{n+1}$.

This is possible, since the collection $\{f : \partial\Delta^m \rightarrow \mathcal{C}_n\}_{m \geq 0}$ is λ -small (Proposition 4.7.4.10) and each of its members admits an extension $\bar{f} : (\partial\Delta^m)^\triangleright \rightarrow \mathcal{C}$. $\square$

Corollary 9.1.7.4. *Let λ be an uncountable regular cardinal. Then every filtered ∞ -category $\mathcal{C}$ can be realized as the colimit of some diagram* 061J

$$A \rightarrow \mathbf{Set}_\Delta \quad (\alpha \in A) \mapsto \mathcal{C}_\alpha,$$

where $(A, \leq)$ is a λ -directed partially ordered set and each $\mathcal{C}_\alpha$ is a λ -small filtered ∞ -category. Moreover, $\mathcal{C}$ is also a colimit of the diagram $\{\mathcal{C}_\alpha\}_{\alpha \in A}$ in the ∞ -category $\mathcal{QC}$.

Our next goal is to prove a variant of Proposition 9.1.7.3 for κ -filtered ∞ -categories. Let κ and λ be regular cardinals, let $\mathcal{C}$ be a κ -filtered ∞ -category, and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a λ -small simplicial subset. Suppose that we wish to find a simplicial subset $\mathcal{C}' \subseteq \mathcal{C}$ containing $\mathcal{C}_0$, where $\mathcal{C}'$ is also a κ -filtered ∞ -category. In this case, every κ -small diagram $f : K \rightarrow \mathcal{C}_0$ needs to admit an extension $\bar{f} : K^\triangleright \rightarrow \mathcal{C}'$. In general, it is not possible to arrange that $\mathcal{C}'$ is also λ -small: there might be “too many” choices for the diagram f . To address this point, we need an additional assumption about the relationship between the cardinals κ and λ .

Definition 9.1.7.5 (Makkai-Paré [44]). Let κ and λ be regular cardinals. We write $\kappa \trianglelefteq \lambda$ 061K if $\kappa \leq \lambda$ and the following additional condition is satisfied:

- For every λ -small set S , there exists a λ -small collection of subsets $\{S_i \subseteq S\}_{i \in I}$ such that each S_i is κ -small, and every κ -small subset of S is contained in some S_i .

We write $\kappa \triangleleft \lambda$ if $\kappa \trianglelefteq \lambda$ and $\kappa \neq \lambda$.

Example 9.1.7.6. Let κ be a regular cardinal. Then $\kappa \trianglelefteq \kappa$. For example, if S is a 061L κ -small set, then the singleton $\{S\}$ is a κ -small collection of subsets of S which satisfies the requirements of Definition 9.1.7.5.

Example 9.1.7.7. Let κ be a regular cardinal with successor κ^+ . Then $\kappa \triangleleft \kappa^+$. That is, if 061M S is a set of cardinality $\leq \kappa$, then there is a collection of subsets $\{S_i\}_{i \in I}$ having cardinality $\leq \kappa$ such that every κ -small subset of S is contained in some S_i . Without loss of generality, we may assume that $S = \text{Ord}_{<\kappa}$ is the set of ordinals α satisfying $\alpha < \kappa$ (Remark 4.7.2.6). In this case, we can take $\{S_i\}_{i \in I}$ to be the collection of all subsets of the form $\text{Ord}_{<\beta}$, where β ranges over $\text{Ord}_{<\kappa}$.

061N **Proposition 9.1.7.8.** *Let $\kappa < \lambda$ be regular cardinals, where λ has exponential cofinality $\geq \kappa$. Then, for every λ -small set S , the collection of κ -small subsets $\{S_i \subseteq S\}_{i \in I}$ is also λ -small. In particular, $\kappa \triangleleft \lambda$.*

Proof. For every ordinal α , let $\text{Ord}_{<\alpha}$ denote the set of ordinals smaller than α . Then a subset $S_i \subseteq S$ is κ -small if and only if it is the image of a function $F : \text{Ord}_{<\alpha} \rightarrow S$, for some ordinal $\alpha < \kappa$. It will therefore suffice to show that the set of all such pairs (α, F) is λ -small. The set $\text{Ord}_{<\kappa}$ has cardinality κ , and is therefore λ -small by virtue of our assumption that $\kappa < \lambda$. Since λ is regular, it will suffice to show that for every fixed ordinal $\alpha < \kappa$, the set of functions $F : \text{Ord}_{<\alpha} \rightarrow S$ is λ -small. This follows from our assumption that λ has exponential cofinality $\geq \kappa$. $\square$

061P **Corollary 9.1.7.9.** *Let $\kappa \leq \lambda$ be regular cardinals. If λ has exponential cofinality $\geq \kappa$, then $\kappa \trianglelefteq \lambda$.*

Proof. The case $\kappa = \lambda$ is trivial (Example 9.1.7.6), and the case $\kappa < \lambda$ follows from Proposition 9.1.7.8. $\square$

061Q **Example 9.1.7.10.** Every regular cardinal λ has exponential cofinality $\geq \aleph_0$ (Remark 4.7.3.17), and therefore satisfies $\aleph_0 \trianglelefteq \lambda$ (Corollary 9.1.7.9).

061R **Example 9.1.7.11.** Let $\kappa \leq \lambda$ be regular cardinals. If λ is strongly inaccessible, then it has exponential cofinality $\geq \kappa$, and therefore satisfies $\kappa \trianglelefteq \lambda$ (Corollary 9.1.7.9).

Proposition 9.1.7.8 admits a weak converse:

061S **Proposition 9.1.7.12.** *Assume the generalized continuum hypothesis, and let $\kappa < \lambda$ be regular cardinals. Then $\kappa \triangleleft \lambda$ if and only if λ has exponential cofinality $\geq \kappa$.*

Proof. Assume that $\kappa \triangleleft \lambda$; we will show that λ has exponential cofinality $\geq \kappa$ (the converse follows from Proposition 9.1.7.8). If λ is strongly inaccessible, this is immediate. Otherwise, we may assume that $\lambda = \lambda_0^+$ is a successor cardinal (Remark 4.7.3.23). Let $\{S_i\}_{i \in I}$ be a κ -small collection of λ -small sets; we wish to show that the product $\prod_{i \in I} S_i$ is λ -small. Fix a set S of cardinality λ_0 . Each of the sets S_i has cardinality $\leq \lambda_0$, and is therefore isomorphic to a subset of S . We may therefore assume without loss of generality that each S_i is equal to S , so that $\prod_{i \in I} S_i$ can be identified with the set $\text{Fun}(I, S)$ of functions from I to S . Set $T = I \times S$. Note that every function $f : I \rightarrow S$ is determined by its graph $\Gamma_f = \{(i, s) \in I \times S : f(i) = s\}$, which is a κ -small subset of T . We will complete the proof by showing that the collection of κ -small subsets of T is λ -small.

Our assumption that $\kappa \triangleleft \lambda$ guarantees that there is a λ -small collection $\{T_j\}_{j \in J}$, where each T_j is a κ -small subset of T and every κ -small subset of T is contained in some T_j . It will therefore suffice to show that, for each $j \in J$, the collection of subsets of T_j is λ -small.

This is clear: since T_j has cardinality $< \kappa$, the generalized continuum hypothesis guarantees that the collection of subsets of T_j has cardinality $\leq \kappa < \lambda$. $\square$

Proposition 9.1.7.13. *Let κ , λ , and μ be regular cardinals satisfying $\kappa \trianglelefteq \lambda$ and $\lambda \trianglelefteq \mu$. 061T Then $\kappa \trianglelefteq \mu$.*

Proof. Let S be a μ -small set. Using our assumption that $\lambda \trianglelefteq \mu$, we can choose a μ -small collection $\{S_i\}_{i \in I}$ of λ -small subsets of S such that every λ -small subset of S is contained in some S_i . For each $i \in I$, our assumption that $\kappa \trianglelefteq \lambda$ guarantees that we can choose a λ -small collection $\{S_{i,j}\}_{j \in J_i}$ of κ -small subsets of S_i such that every κ -small subset of S_i is contained in some $S_{i,j}$. Then $\{S_{i,j}\}_{i \in I, j \in J_i}$ is a μ -small collection of κ -small subsets of S , and every κ -small subset of S is contained in some $S_{i,j}$. $\square$

We now return to the study of ∞ -categories.

Proposition 9.1.7.14. *Let κ and λ be regular cardinals satisfying $\kappa \triangleleft \lambda$, let $\mathcal{C}$ be a κ -filtered 061U ∞ -category, and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a λ -small simplicial subset. Then $\mathcal{C}_0$ is contained in a λ -small simplicial subset $\mathcal{C}' \subseteq \mathcal{C}$ which is also a κ -filtered ∞ -category.*

Proof. We use a variant of the proof of Proposition 9.1.7.3. We first claim that for every λ -small simplicial subset $X \subseteq \mathcal{C}$, we can find a larger λ -small simplicial subset $X^+ \subseteq \mathcal{C}$ satisfying the following conditions:

- (1) For $0 < i < n$, every morphism $\Lambda_i^n \rightarrow X$ can be extended to an n -simplex of X^+ .
- (2) For $n \geq 0$, every morphism $\partial \Delta^n \rightarrow X$ can be extended to a morphism $(\partial \Delta^n)^\triangleright \rightarrow X^+$.
- (3) For every object $C \in \mathcal{C}$ which is contained in X and every κ -small collection of morphisms $\{f_i : C \rightarrow D_i\}_{i \in I}$ which are also contained in X , there exists a morphism $h : C \rightarrow E$ which is contained in X^+ and a collection of 2-simplices $\{\sigma_i\}_{i \in I}$ of X^+ with boundary indicated in the diagram

$$\begin{array}{ccc}
 & D_i & \\
 f_i \nearrow & & \searrow \\
 C & \xrightarrow{h} & E.
 \end{array}$$

Arranging (1) and (2) is straightforward (see the proofs of Proposition 9.1.7.1 and 9.1.7.3, respectively). To guarantee that condition (3) is satisfied, we need to work a bit harder. Let us first regard the object C as fixed, and let $\{f_s : C \rightarrow D_s\}_{s \in S}$ be the collection of all morphisms with source C which are contained in X . Since the simplicial set X is λ -small,

the set S is λ -small. Invoking our assumption that $\kappa \triangleleft \lambda$, we can choose a λ -small collection $\{S_j\}_{j \in J}$, where each S_j is a κ -small subset of S and every κ -small subset of S is contained in some S_j . It follows that, to verify condition (3) for the object C , we may assume that $I = S_j$ for some $j \in J$. If we regard j as fixed, then our assumption that $\mathcal{C}$ is κ -filtered guarantees that there exists a morphism $h_j : C \rightarrow E_j$ and a collection of 2-simplices $\{\sigma_{i,j}\}_{i \in S_j}$ with boundary indicated in the diagram

$$\begin{array}{ccc} & D_i & \\ f_i \nearrow & & \searrow \\ C & \xrightarrow{h_j} & E_j. \end{array}$$

We can therefore guarantee that condition (3) is satisfied by demanding that X^+ contains each of the morphisms h_j and each of the 2-simplices $\sigma_{i,j}$, where C ranges over all vertices of X , j ranges over all elements of the set J (which depends on C), and i ranges over all elements of the set S_j .

We now construct a transfinite sequence $\{\mathcal{C}_\beta\}_{\beta < \kappa}$ of λ -small simplicial subsets of $\mathcal{C}$ as follows:

- If $\beta = \alpha + 1$ is a successor ordinal, we take $\mathcal{C}_\beta = \mathcal{C}_\alpha^+$.
- If $\beta < \kappa$ is a nonzero limit ordinal, we take $\mathcal{C}_\beta = \bigcup_{\alpha < \beta} \mathcal{C}_\alpha$.

Set $\mathcal{C}' = \bigcup_{\beta < \kappa} \mathcal{C}_\beta$. Since $\kappa < \lambda$, our assumption that λ is regular guarantees that $\mathcal{C}'$ is also λ -small. Moreover, our construction guarantees that the simplicial set $\mathcal{C}'^+ = \mathcal{C}'$ satisfies condition (1), (2), and (3) above. Condition (1) guarantees that $\mathcal{C}'$ is an ∞ -category, condition (2) guarantees that $\mathcal{C}'$ is filtered (Lemma 9.1.2.12), and condition (3) guarantees that it is also κ -filtered (Proposition 9.1.5.10). $\square$

061V Warning 9.1.7.15. In the statement of Proposition 9.1.7.14, the assumption $\kappa \triangleleft \lambda$ cannot be omitted. For example, let S be a λ -small set, let Q be the collection of all κ -small subsets of S (partially ordered by inclusion). Set $\mathcal{C} = N_\bullet(Q)$, and let $\mathcal{C}_0$ be the full subcategory of $\mathcal{C}$ spanned by the singleton sets $\{s\}$ for $s \in S$. If $\mathcal{C}' \subseteq \mathcal{C}$ is a simplicial subset satisfying the conclusion of Proposition 9.1.7.14, then the collection of vertices of $\mathcal{C}'$ can be viewed as a λ -small collection $\{S_i\}_{i \in I}$ of κ -small subsets of S , such that every κ -small subset of S is contained in some S_i .

061W Corollary 9.1.7.16. *Let κ and λ be regular cardinals satisfying $\kappa \triangleleft \lambda$. Then every κ -filtered ∞ -category $\mathcal{C}$ can be realized as the colimit of some diagram*

$$A \rightarrow \text{Set}_\Delta \quad (\alpha \in A) \mapsto \mathcal{C}_\alpha,$$

where $(A, \leq)$ is a λ -directed partially ordered set and each $\mathcal{C}_\alpha$ is a λ -small κ -filtered ∞ -category. Moreover, $\mathcal{C}$ is also a colimit of the diagram $\{\mathcal{C}_\alpha\}_{\alpha \in A}$ in the ∞ -category $\mathcal{QC}$.

Remark 9.1.7.17. Corollary 9.1.7.16 has a counterpart in the degenerate case $\kappa = \lambda$, which we will discuss in §9.1.8 (see Proposition 9.1.8.5). 061X

In the situation of Corollary 9.1.7.16, it will be useful to know that if we have some bound on the size of the ∞ -category $\mathcal{C}$, then we can arrange a corresponding bound on the size of the partially ordered set A . This requires some set-theoretic assumptions of the same nature we have discussed above.

Lemma 9.1.7.18. Let λ and μ be regular cardinals satisfying $\lambda \trianglelefteq \mu$, and let $X_\bullet$ be a μ -small simplicial set. Then there is a μ -small collection $\{X(i)_\bullet\}_{i \in I}$, where each $X(i)_\bullet$ is a λ -small simplicial subset of $X_\bullet$, and every λ -small simplicial subset of $X_\bullet$ is contained in some $X(i)_\bullet$. 061Y

Proof. If $\kappa = \aleph_0$, we can take $\{X(i)_\bullet\}$ to be the collection of all finite simplicial subsets of $X_\bullet$. We may therefore assume without loss of generality that κ is uncountable. Let $S = \coprod_{n \geq 0} X_n$ denote the collection of all simplices of X . The assumption $\kappa \trianglelefteq \lambda$ guarantees that there is a λ -small collection $\{S(i)\}_{i \in I}$ of κ -small subsets of S such that every κ -small subset of S is contained in some $S(i)$. Enlarging the subsets $S(i)$ if necessary, we may assume that they are closed under the face and degeneracy operators for the simplicial set $X_\bullet$. It follows that each $S(i)$ can be identified with the collection of simplices for some κ -small simplicial subset $X(i)_\bullet \subseteq X$. By construction, the collection of simplicial subsets $\{X(i)_\bullet\}_{i \in I}$ has the desired property. $\square$

Remark 9.1.7.19. In the situation of Lemma 9.1.7.18, the collection of simplicial subsets $\{X(i) \subseteq X\}_{i \in I}$ is automatically λ -directed (when regarded as partially ordered with respect to inclusion). 061Z

Proposition 9.1.7.20. Let κ , λ , and μ be regular cardinals satisfying $\kappa \triangleleft \lambda$ and $\lambda \trianglelefteq \mu$. Then every μ -small κ -filtered ∞ -category $\mathcal{C}$ can be realized as the colimit of some diagram 0620

$$A \rightarrow \mathbf{Set}_\Delta \quad (\alpha \in A) \mapsto \mathcal{C}_\alpha,$$

where $(A, \leq)$ is a μ -small λ -directed partially ordered set and each $\mathcal{C}_\alpha$ is a λ -small κ -filtered ∞ -category. Moreover, $\mathcal{C}$ is also a colimit of the diagram $\{\mathcal{C}_\alpha\}_{\alpha \in A}$ in the ∞ -category $\mathcal{QC}_{<\mu}$.

Proof. Using Lemma 9.1.7.18, we can choose a μ -small collection $\{\mathcal{C}_\alpha\}_{\alpha \in A}$ of λ -small simplicial subsets of $\mathcal{C}$ such that every λ -small simplicial subset of $\mathcal{C}$ is contained in some $\mathcal{C}_\alpha$. Enlarging the simplicial subsets $\mathcal{C}_\alpha$ if necessary, we may assume that they are κ -filtered ∞ -categories (Proposition 9.1.7.14). The index set A is then λ -directed by inclusion (Remark 9.1.7.19), and $\mathcal{C} = \bigcup_\alpha \mathcal{C}_\alpha$ is the colimit of the diagram $\{\mathcal{C}_\alpha\}$ in the category of simplicial sets. The final assertion follows from Corollary 9.1.6.3. $\square$

0621 **Variant 9.1.7.21.** Let λ and μ be uncountable regular cardinals satisfying $\lambda \leq \mu$. Then every μ -small ∞ -category $\mathcal{C}$ can be realized as the colimit of some diagram

$$A \rightarrow \mathbf{Set}_\Delta \quad (\alpha \in A) \mapsto \mathcal{C}_\alpha,$$

where $(A, \leq)$ is a μ -small λ -directed partially ordered set and each $\mathcal{C}_\alpha$ is a λ -small ∞ -category. Moreover, if $\mathcal{C}$ is filtered, we can arrange that each $\mathcal{C}_\alpha$ is filtered.

Proof. Combine Lemma 9.1.7.18 with Proposition 9.1.7.1 (or Proposition 9.1.7.3, in the case where $\mathcal{C}$ is filtered). $\square$

9.1.8 Approximation by Partially Ordered Sets

02Q8 Let $\mathcal{C}$ be an ∞ -category. It follows from Corollary 9.1.5.13 (and Example 9.1.1.2) that if there exists a directed partially ordered set $(A, \leq)$ and a right cofinal functor $N_\bullet(A) \rightarrow \mathcal{C}$, then $\mathcal{C}$ is filtered. The goal of this section is to show that the converse is also true.

0622 **Theorem 9.1.8.1.** *Let $\mathcal{C}$ be an ∞ -category. Then $\mathcal{C}$ is filtered if and only if there exists a directed partially ordered set $(A, \leq)$ and a right cofinal functor $N_\bullet(A) \rightarrow \mathcal{C}$.*

We will deduce Theorem 9.1.8.1 from a more precise result (which applies also to κ -filtered ∞ -categories, and allows us to control the size of the partially ordered set A) which we prove at the end of this section (Theorem 9.1.8.7). We begin with some preliminaries.

02QB **Lemma 9.1.8.2.** *Let κ be an infinite cardinal and let $\mathcal{C}$ be a κ -filtered ∞ -category. Then there exists a trivial Kan fibration $\pi : \tilde{\mathcal{C}} \rightarrow \mathcal{C}$, where $\tilde{\mathcal{C}}$ is an ∞ -category having the following property:*

(*) *For every κ -small simplicial subset $K \subseteq \tilde{\mathcal{C}}$, the inclusion map $K \hookrightarrow \tilde{\mathcal{C}}$ extends to a monomorphism $K^\triangleright \hookrightarrow \tilde{\mathcal{C}}$.*

Proof. Let J be a set of cardinality κ and let $\mathcal{J}$ be the corresponding indiscrete category (that is, the category having object set $\mathrm{Ob}(\mathcal{J}) = J$ and $\mathrm{Hom}_{\mathcal{J}}(j, j') = *$ for every pair of elements $j, j' \in J$). The nerve $N_\bullet(\mathcal{J})$ is a contractible Kan complex. Setting $\tilde{\mathcal{C}} = N_\bullet(\mathcal{J}) \times \mathcal{C}$, it follows that the projection map $\pi : \tilde{\mathcal{C}} \rightarrow \mathcal{C}$ is a trivial Kan fibration. We will complete the proof by showing that $\tilde{\mathcal{C}}$ satisfies condition (*). Let K be a κ -small simplicial subset of $\tilde{\mathcal{C}}$, so that the inclusion map $K \hookrightarrow \tilde{\mathcal{C}}$ can be identified with a pair of morphisms

$$f : K \rightarrow N_\bullet(\mathcal{J}) \quad g : K \rightarrow \mathcal{C}.$$

Since J has cardinality κ , we can choose an element $j \in J$ which is not of the form $f(x)$ for any vertex $x \in K$. It follows that f admits a unique extension $\bar{f} : K^\triangleright \rightarrow N_\bullet(\mathcal{J})$ which carries the cone point of $K^\triangleright$ to the element $j \in J$. Our assumption that $\mathcal{C}$ is κ -filtered guarantees that g admits an extension $\bar{g} : K^\triangleright \rightarrow \mathcal{C}$. We complete the proof by observing that the pair $(\bar{f}, \bar{g})$ determines a monomorphism of simplicial sets $K^\triangleright \rightarrow \tilde{\mathcal{C}}$. $\square$

Remark 9.1.8.3. In the situation of Lemma 9.1.8.2, if the ∞ -category $\mathcal{C}$ is λ -small for some cardinal $\lambda > \kappa$, then the ∞ -category $\tilde{\mathcal{C}}$ constructed in the proof is also λ -small. 0623

Lemma 9.1.8.4. Let κ be a regular cardinal and let $\mathcal{C}$ be a simplicial set which is a κ -filtered ∞ -category which satisfies condition $(*)$ of Lemma 9.1.8.2. Then $\mathcal{C}$ can be realized as the colimit of a diagram 0624

$$A \rightarrow \mathbf{Set}_\Delta \quad (\alpha \in A) \mapsto X_\alpha,$$

where $(A, \leq)$ is a κ -directed partially ordered set and each X_α is a simplicial set of the form $K_\alpha^\triangleright$ for some κ -small simplicial set K_α . Moreover, if $\mathcal{C}$ is μ -small for some regular cardinal λ with $\kappa \leq \lambda$, then we can arrange that A is also λ -small.

Proof. Fix a regular cardinal λ such that $\mathcal{C}$ is λ -small. If $\kappa \leq \lambda$, then we can choose a λ -small collection $\{K_\alpha\}_{\alpha \in A}$ of κ -small simplicial subsets of $\mathcal{C}$, such that every κ -small simplicial subset of $\mathcal{C}$ is contained in some K_α (Lemma 9.1.7.18). Since $\mathcal{C}$ satisfies condition $(*)$, each K_α is contained in a larger simplicial subset $X_\alpha \subseteq \mathcal{C}$ which is isomorphic to the cone $K_\alpha^\triangleright$. We regard A as a partially ordered set, where $\alpha \leq \beta$ if X_α is contained in X_β . Then $(A, \leq)$ is automatically κ -directed (Remark 9.1.7.19), and the colimit $\varinjlim_{\alpha \in A} X_\alpha$ identifies with the union $\bigcup_\alpha X_\alpha = \mathcal{C}$. $\square$

Lemma 9.1.8.4 has the following homotopy-invariant consequence:

Proposition 9.1.8.5. Let κ and λ be regular cardinals satisfying $\kappa \triangleleft \lambda$, and let $\mathcal{C}$ be an ∞ -category which is κ -filtered and essentially λ -small. Then there exists a λ -small κ -directed partially ordered set A and a diagram 0625

$$\mathbf{N}_\bullet(A) \rightarrow \mathcal{QC}_{<\lambda} \quad (\alpha \in A) \mapsto \mathcal{E}_\alpha$$

having colimit $\mathcal{C}$ which satisfies the following condition:

$(*)$ For each $\alpha \in A$, there exists a κ -small simplicial set K_α and a categorical equivalence $K_\alpha^\triangleright \rightarrow \mathcal{E}_\alpha$.

Remark 9.1.8.6. In the situation of Proposition 9.1.8.5, condition $(*)$ guarantees that each of the ∞ -categories $\mathcal{E}_\alpha$ has a final object (and is therefore μ -filtered for any infinite cardinal μ ; see Example 9.1.1.6). Beware that these final objects need not be preserved by the transition maps $\mathcal{E}_\alpha \rightarrow \mathcal{E}_\beta$. 0626

Proof of Proposition 9.1.8.5. Replacing $\mathcal{C}$ by an equivalent ∞ -category, we may assume that it is λ -small and satisfies condition $(*)$ of Lemma 9.1.8.2. Using Lemma 9.1.8.4, we can realize $\mathcal{C}$ as the colimit of a diagram

$$\mathcal{F} : A \rightarrow \mathbf{Set}_\Delta \quad (\alpha \in A) \mapsto X_\alpha,$$

where each X_α has the form $K_\alpha^\triangleright$ for some κ -small simplicial set K_α . Using Proposition 4.1.3.2, we can choose a levelwise categorical equivalence $\mathcal{F} \rightarrow \mathcal{F}'$ for some functor

$$\mathcal{F}' : A \rightarrow \mathbf{Set}_\Delta \quad (\alpha \in A) \mapsto \mathcal{E}_\alpha$$

carrying each $\alpha \in A$ to an ∞ -category $\mathcal{E}_\alpha$. By construction, each of the ∞ -categories $\mathcal{E}_\alpha$ essentially λ -small, so that $\mathcal{F}'$ determines a diagram $\mathbf{N}_\bullet(A) \rightarrow \mathcal{QC}_{<\lambda}$. It follows from Corollary 9.1.6.3 that $\mathcal{C}$ is a colimit of this diagram. $\square$

Theorem 9.1.8.1 is a consequence of the following more precise assertion:

02QA Theorem 9.1.8.7. *Let κ and λ be regular cardinals satisfying $\kappa \triangleleft \lambda$ and let $\mathcal{C}$ be a λ -small κ -filtered ∞ -category. Then there exists a λ -small κ -directed partially ordered set A and a right cofinal functor $F : \mathbf{N}_\bullet(A) \rightarrow \mathcal{C}$.*

Proof. Using Proposition 9.1.8.5 (and Remark 9.1.8.6), we can choose a λ -small κ -directed partially ordered set $(A, \leq)$ and a diagram

$$\mathcal{F} : \mathbf{N}_\bullet(A) \rightarrow \mathcal{QC}_{<\lambda} \quad (\alpha \in A) \mapsto \mathcal{E}_\alpha$$

having colimit $\mathcal{C}$, where each $\mathcal{E}_\alpha$ has a final object. Let $U : \mathcal{E} \rightarrow \mathbf{N}_\bullet(A)$ be a cocartesian fibration with covariant transport representation $\mathcal{F}$ (for example, we can take $\mathcal{E}$ to be the ∞ -category of elements $\int_{\mathcal{C}} \mathcal{F}$ of Definition 5.6.2.1) and let W be the collection of all U -cocartesian morphisms of $\mathcal{E}$. Since $\mathcal{C}$ is a colimit of the diagram $\mathcal{F}$, there is a functor $G : \mathcal{E} \rightarrow \mathcal{C}$ which exhibits $\mathcal{C}$ as a localization of $\mathcal{E}$ with respect to W (Proposition 7.4.5.20), and is therefore right cofinal (Proposition 7.2.1.10). Since each fiber of U has a final object, the functor U is a reflective localization (Corollary 7.1.5.22): that is, it has a (fully faithful) right adjoint $V : \mathbf{N}_\bullet(A) \rightarrow \mathcal{E}$. The functor V is also right cofinal (Corollary 7.2.3.7), so the composition $(G \circ V) : \mathbf{N}_\bullet(A) \rightarrow \mathcal{C}$ is right cofinal. $\square$

0627 Corollary 9.1.8.8. *Let $\mathcal{C}$ be an ∞ -category and let κ be a regular cardinal. Then $\mathcal{C}$ is κ -filtered if and only if there exists a κ -directed partially ordered set $(A, \leq)$ and a right cofinal functor $\mathbf{N}_\bullet(A) \rightarrow \mathcal{C}$.*

Proof. Combine Corollary 9.1.5.13 with Theorem 9.1.8.7. $\square$

06D8 Corollary 9.1.8.9. *Let κ be a regular cardinal and let $\mathcal{C}$ be an ∞ -category which is κ^+ -small and κ -filtered. Then there exists a right cofinal functor $\mathbf{N}_\bullet(\mathbf{Ord}_{<\kappa}) \rightarrow \mathcal{C}$. Here $\mathbf{Ord}_{<\kappa}$ denotes the collection of ordinals smaller than κ .*

Proof. Since $\kappa \leq \kappa^+$ (see Example 9.1.7.7), we can use Theorem 9.1.8.7 to reduce to the case where $\mathcal{C} = \mathbf{N}_\bullet(A)$, where $(A, \leq)$ is a κ -directed partially ordered set of cardinality $\leq \kappa$. Choose a surjective map of sets $f : \mathbf{Ord}_{<\kappa} \rightarrow A$. Let Q denote the collection of all

pairs $(\alpha, g_{<\alpha})$, where $\alpha \leq \kappa$ is an ordinal and $g_{<\alpha} : \text{Ord}_{<\alpha} \rightarrow A$ is a nondecreasing function satisfying $g_{<\alpha}(\alpha_0) \geq f(\alpha_0)$ for each $\alpha_0 < \alpha$. We regard Q as a partially ordered set, where $(\alpha, g_{<\alpha}) \leq (\beta, g_{<\beta})$ if $\alpha \leq \beta$ and $g_{<\alpha} = g_{<\beta}|_{\text{Ord}_{<\alpha}}$. The partially ordered set Q satisfies the hypotheses of Zorn's lemma, and therefore has a maximal element $(\gamma, g_{<\gamma})$. If $\gamma < \kappa$, then $\{f(\gamma)\} \cup \{g_{<\gamma}(\alpha) : \alpha < \gamma\}$ is a κ -small subset of A , and therefore admits an upper bound $a \in A$. In this case, we can extend $g_{<\gamma}$ to a nondecreasing function $g_{\leq\gamma} : \text{Ord}_{\leq\gamma} \rightarrow A$ by setting $g_{\leq\gamma}(\gamma) = a$, contradicting the maximality of the pair $(\gamma, g_{<\gamma})$. It follows that $\gamma = \kappa$: that is, we can regard $g_{<\gamma}$ as a nondecreasing function from $\text{Ord}_{<\kappa} \rightarrow A$. Using Example 9.1.4.10, we see that the induced map $N_\bullet(\text{Ord}_{<\kappa}) \rightarrow N_\bullet(A)$ is a right cofinal functor of ∞ -categories. $\square$

Corollary 9.1.8.10. *Let $\mathcal{C}$ be a filtered ∞ -category having countably many simplices. Then there exists a right cofinal functor $F : N_\bullet(\mathbf{Z}_{\geq 0}) \rightarrow \mathcal{C}$. Here $\mathbf{Z}_{\geq 0}$ denotes the set of non-negative integers, equipped with its usual ordering.* 0628

Proof. Apply Corollary 9.1.8.9 in the special case $\kappa = \aleph_0$. $\square$

Beware that Theorem 9.1.8.7 is not true in the case $\kappa = \lambda$. Note that a partially ordered set $(A, \leq)$ which is both κ -small and κ -directed must have a largest element. Consequently, if there exists a right cofinal functor $N_\bullet(A) \rightarrow \mathcal{C}$, then the ∞ -category $\mathcal{C}$ must have a final object. The assumption that $\mathcal{C}$ is κ -small and κ -filtered guarantees something slightly weaker:

Proposition 9.1.8.11. *Let κ be an infinite cardinal and let $\mathcal{C}$ be an ∞ -category which is κ -small. The following conditions are equivalent:* 0629

- (1) *The ∞ -category $\mathcal{C}$ is κ -filtered.*
- (2) *The idempotent-completion of $\mathcal{C}$ has a final object.*
- (3) *There exists a right cofinal functor $N_\bullet(\text{Idem}) \rightarrow \mathcal{C}$.*

In particular, if $\mathcal{C}$ is idempotent-complete, then it is κ -filtered if and only if it has a final object.

Proof. The equivalence (2) $\Leftrightarrow$ (3) follows from Remark 8.5.6.19 (and does not require the assumption that $\mathcal{C}$ is κ -small). Since the ∞ -category $N_\bullet(\text{Idem})$ is κ -filtered (Example 9.1.1.9), the implication (3) $\Rightarrow$ (1) is a special case of Corollary 9.1.5.13. We will complete the proof by showing that (1) implies (2). If condition (1) is satisfied, then there exists an object $X \in \mathcal{C}$ and a natural transformation $\alpha : \text{id}_{\mathcal{C}} \rightarrow \underline{X}$ in the ∞ -category $\text{Fun}(\mathcal{C}, \mathcal{C})$. Fix an uncountable cardinal λ such that $\mathcal{C}$ is locally λ -small, let $\widehat{\mathcal{C}}$ denote the ∞ -category $\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$, and let $H : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ be a covariant Yoneda embedding for $\mathcal{C}$. Since H is dense (Theorem 8.4.2.1), every object $\mathcal{F} \in \widehat{\mathcal{C}}$ can be recovered as the colimit of the diagram

$$\mathcal{C} \times_{\widehat{\mathcal{C}}} \widehat{\mathcal{C}}_{/\mathcal{F}} \rightarrow \mathcal{C} \xrightarrow{H} \widehat{\mathcal{C}}.$$

In particular, if $\mathcal{F}$ is a final object of $\widehat{\mathcal{C}}$, then it is a colimit of the diagram H . It follows that there exists a morphism $i : \mathcal{F} \rightarrow H(X)$ in the ∞ -category $\widehat{\mathcal{C}}$ and a commutative diagram

$$\begin{array}{ccc} & \mathcal{F} & \\ H \nearrow & & \searrow i \\ & H(X) & \end{array} \quad \text{with a horizontal arrow } H \xrightarrow{H(\alpha)} H(X)$$

in the ∞ -category $\text{Fun}(\mathcal{C}, \widehat{\mathcal{C}})$. Since $\mathcal{F}$ is a final object of $\widehat{\mathcal{C}}$, the morphism i automatically has a left homotopy inverse (given by any morphism $r : H(X) \rightarrow \mathcal{F}$). In particular, $\mathcal{F}$ is a retract of $H(X)$, and can therefore be viewed as a final object in the idempotent-completion of $\mathcal{C}$ (see Proposition 8.5.5.5). $\square$

062A Corollary 9.1.8.12. *Let $\mathcal{C}$ be an ∞ -category which is finite when viewed as a simplicial set. Then $\mathcal{C}$ is filtered if and only if it has a final object.*

Proof. This follows from Proposition 9.1.8.11 (applied in the special case $\kappa = \aleph_0$), since the ∞ -category $\mathcal{C}$ is automatically idempotent-complete (Example 8.5.4.5). $\square$

9.1.9 Filtered Colimits of ∞ -Categories

062Y We now exploit the results of §9.1.6 and §9.1.8 to study filtered colimits in the ∞ -category $\mathcal{QC}$.

062Z Proposition 9.1.9.1. *Let $\mathcal{F} : \mathcal{J} \rightarrow \mathcal{QC}$ be a filtered diagram of ∞ -categories. Assume that, for every object $J \in \mathcal{J}$, the ∞ -category $\mathcal{F}(J)$ is locally n -truncated, for some fixed integer n . Then the colimit $\varinjlim(\mathcal{F})$ is also locally n -truncated.*

Proof. Using Theorem 9.1.8.1, we can choose a directed partially ordered set $(A, \leq)$ and a right cofinal functor $N_\bullet(A) \rightarrow \mathcal{J}$. Using Corollary 7.2.2.11, we can replace $\mathcal{J}$ by $N_\bullet(A)$ and thereby reduce to the case where $\mathcal{J}$ is the nerve of a (directed) partially ordered set. Using Corollary 5.6.5.18, we can further reduce to the case where $\mathcal{F}$ is obtained from a strictly commutative diagram

$$\mathcal{F}_0 : (A, \leq) \rightarrow \mathcal{QC}at \subset \mathcal{Set}_\Delta \quad (\alpha \in A) \mapsto \mathcal{E}_\alpha.$$

It follows from Corollary 9.1.6.3 that we can identify the colimit $\varinjlim(\mathcal{F})$ (formed in the ∞ -category $\mathcal{QC}$) with the colimit $\varinjlim(\mathcal{F}_0)$ (formed in the ordinary category of simplicial sets). The desired result now follows from Remark 4.8.2.4. $\square$

Remark 9.1.9.2. In the formulation of Proposition 9.1.9.1, we have implicitly assumed 0630 that the filtered ∞ -category $\mathcal{J}$ is small (so that the colimit $\varinjlim(\mathcal{F})$ is well-defined). More generally, suppose that λ is an uncountable regular cardinal and $\mathcal{F} : \mathcal{J} \rightarrow \mathcal{QC}_{<\lambda}$ is a λ -small filtered diagram. If each of the ∞ -categories $\mathcal{F}(J)$ is locally n -truncated (for some fixed integer n), then the colimit $\varinjlim(\mathcal{F}) \in \mathcal{QC}_{<\lambda}$ is also locally n -truncated. Similar remarks apply to the other results proved in this section.

Variant 9.1.9.3. Let $\mathcal{F} : \mathcal{J} \rightarrow \mathcal{S}$ be a filtered diagram of spaces. Assume that, for every 0631 object $C \in \mathcal{C}$, the Kan complex $\mathcal{F}(C)$ is n -truncated for some fixed integer n . Then the colimit $\varinjlim(\mathcal{F})$ is also n -truncated.

The proof of Proposition 9.1.9.1 can be adapted to prove many similar results.

Proposition 9.1.9.4. Let $\mathcal{F} : \mathcal{J} \rightarrow \mathcal{QC}$ be a filtered diagram of ∞ -categories. Suppose 042P that each of the ∞ -categories $\mathcal{F}(J)$ is idempotent-complete. Then the colimit $\varinjlim(\mathcal{F})$ is also idempotent-complete.

Proof. As in the proof of Proposition 9.1.9.1, we can assume that $\mathcal{J} = \mathbf{N}_\bullet(A)$ is the nerve of a directed partially ordered set $(A, \leq)$ and that $\mathcal{F}$ is obtained from a strictly commutative diagram $\mathcal{F}_0 : (A, \leq) \rightarrow \mathbf{QCat} \subset \mathbf{Set}_\Delta$. Using Corollary 9.1.6.3, we are reduced to proving that the colimit $\varinjlim(\mathcal{F}_0)$ (formed in the category of simplicial sets) is idempotent-complete, which follows from Corollary 8.5.9.10. $\square$

Proposition 9.1.9.5. Let κ be a regular cardinal, let K be a κ -small simplicial set, and 0632 let $\mathcal{F} : \mathcal{J} \rightarrow \mathcal{QC}$ be a κ -filtered diagram of ∞ -categories. Assume that, for every morphism $u : J \rightarrow J'$ of $\mathcal{C}$, the functor $\mathcal{F}(u) : \mathcal{F}(J) \rightarrow \mathcal{F}(J')$ preserves K -indexed colimits. Then, for every object $J \in \mathcal{J}$, the natural map $\mathcal{F}(J) \rightarrow \varinjlim(\mathcal{F})$ preserves K -indexed colimits.

The proof of Proposition 9.1.9.5 will require some preliminaries. We begin with some simple observations.

Lemma 9.1.9.6. Let κ be a regular cardinal and let $\mathcal{C}$ be the colimit of a diagram of 0633 simplicial sets $\{C_\alpha\}_{\alpha \in A}$ indexed by a κ -directed partially ordered set $(A, \leq)$. Let $F : K \rightarrow \mathcal{C}$ be a morphism of simplicial sets which is obtained as the colimit of a compatible system of morphisms $F_\alpha : K \rightarrow C_\alpha$. If K is κ -small, then the canonical map $\theta_\bullet : \varinjlim_\alpha (C_\alpha)_{F_\alpha} \rightarrow \mathcal{C}_F$ is an isomorphism of simplicial sets.

Proof. Fix an integer $n \geq 0$; we wish to show that $\theta_\bullet$ is bijective on simplices of dimension n .

Unwinding the definitions, we see that θ_n is obtained from a commutative diagram of sets

$$\begin{array}{ccc} \varinjlim_{\alpha} \mathrm{Hom}_{\mathrm{Set}_{\Delta}}(K \star \Delta^n, \mathcal{C}_{\alpha}) & \longrightarrow & \mathrm{Hom}_{\mathrm{Set}_{\Delta}}(K \star \Delta^n, \mathcal{C}) \\ \downarrow & & \downarrow \\ \varinjlim_{\alpha} \mathrm{Hom}_{\mathrm{Set}_{\Delta}}(K, \mathcal{C}_{\alpha}) & \longrightarrow & \mathrm{Hom}_{\mathrm{Set}_{\Delta}}(K, \mathcal{C}) \end{array}$$

by passing to fibers in the vertical direction. It will therefore suffice to show that the horizontal maps are bijective. Since $(A, \leq)$ is κ -directed, this follows from the fact that K and $K \star \Delta^n$ are κ -small simplicial sets (see Variant 9.2.5.10). $\square$

0634 Lemma 9.1.9.7. *Let κ be a regular cardinal and let $\mathcal{C}$ be the colimit of a diagram of simplicial sets $\{\mathcal{C}_{\alpha}\}_{\alpha \in A}$ indexed by a κ -directed partially ordered set $(A, \leq)$. Let K be a κ -small simplicial set and let $\overline{F} : K^{\triangleright} \rightarrow \mathcal{C}$ be a morphism of simplicial sets which is obtained as the colimit of a compatible system of morphisms $\overline{F}_{\alpha} : K^{\triangleright} \rightarrow \mathcal{C}_{\alpha}$. Assume that each $\mathcal{C}_{\alpha}$ is an ∞ -category and that each $\overline{F}_{\alpha}$ is a colimit diagram in $\mathcal{C}_{\alpha}$. Then $\mathcal{C}$ is an ∞ -category and $\overline{F}$ is a colimit diagram in $\mathcal{C}$.*

Proof. The first assertion follows from Remark 1.4.0.9. To prove the second, set $F = \overline{F}|_K$ and $F_{\alpha} = (\overline{F}_{\alpha})|_K$ for each $\alpha \in A$. By virtue of Proposition 7.1.3.13, it will suffice to show that the restriction map $\theta : \mathcal{C}_{\overline{F}/} \rightarrow \mathcal{C}_{F/}$ is a trivial Kan fibration. Using Lemma 9.1.9.6, we can realize θ as a filtered colimit of restriction maps $\theta_{\alpha} : (\mathcal{C}_{\alpha})_{\overline{F}_{\alpha}/} \rightarrow (\mathcal{C}_{\alpha})_{F_{\alpha}/}$. Our hypothesis guarantees that each θ_{α} is a trivial Kan fibration (Proposition 7.1.3.13), so that θ is also a trivial Kan fibration (Remark 1.5.5.3). $\square$

Proof of Proposition 9.1.9.5. Let $\mathcal{F} : \mathcal{J} \rightarrow \mathcal{QC}$ be a κ -filtered diagram of ∞ -categories, let K be a κ -small simplicial set, and suppose that each of the transition functors $\mathcal{F}(J) \rightarrow \mathcal{F}(J')$ preserves K -indexed colimits. As in the proof of Proposition 9.1.9.1, we can reduce to the case where $\mathcal{J} = \mathbf{N}_{\bullet}(A)$ is the nerve of a κ -directed partially ordered set $(A, \leq)$ and $\mathcal{F}$ is obtained from a strictly commutative diagram of simplicial sets

$$(A, \leq) \rightarrow \mathbf{QCat} \subset \mathrm{Set}_{\Delta} \quad (\alpha \in A) \mapsto \mathcal{C}_{\alpha}.$$

In this case, we are reduced to showing that each of the functors $\mathcal{C}_{\beta} \rightarrow \varinjlim_{\alpha \in A} \mathcal{C}_{\alpha}$ preserves K -indexed colimits (where the colimit is formed in the ordinary category of simplicial sets). Replacing A by the subset $A_{\geq \beta} = \{\alpha \in A : \alpha \geq \beta\}$, we can reduce to the case where β is the least element of A . In this case, the result follows from Lemma 9.1.9.7. $\square$

0635 Proposition 9.1.9.8. *Let κ be a regular cardinal, let K be a κ -small simplicial set, and let $\mathcal{F} : \mathcal{J} \rightarrow \mathcal{QC}$ be a κ -filtered diagram of ∞ -categories satisfying the following conditions:*

- (1) For each $J \in \mathcal{J}$, the ∞ -category $\mathcal{F}(J)$ admits K -indexed colimits.
- (2) For each morphism $u : J \rightarrow J'$ in $\mathcal{J}$, the functor $\mathcal{F}(u) : \mathcal{F}(J) \rightarrow \mathcal{F}(J')$ preserves K -indexed colimits.

Then the colimit $\varinjlim(\mathcal{F})$ admits K -indexed colimits. Moreover, a functor of ∞ -categories $T : \varinjlim(\mathcal{F}) \rightarrow \mathcal{D}$ preserves K -indexed colimits if and only if, for each $J \in \mathcal{J}$, the composite functor $T_J : \mathcal{F}(J) \rightarrow \varinjlim(\mathcal{F}) \rightarrow \mathcal{D}$ preserves K -indexed colimits.

Proof. As in the proof of Proposition 9.1.9.1, we can reduce to the case where $\mathcal{J} = \mathbf{N}_\bullet(A)$ is the nerve of a κ -directed partially ordered set $(A, \leq)$ and $\mathcal{F}$ is obtained from a strictly commutative diagram of simplicial sets

$$(A, \leq) \rightarrow \mathbf{QCat} \subset \mathbf{Set}_\Delta \quad (\alpha \in A) \mapsto \mathcal{C}_\alpha.$$

Set $\mathcal{C} = \varinjlim_\alpha \mathcal{C}_\alpha$, where the colimit is formed in the category of simplicial sets. Since $(A, \leq)$ is κ -directed and K is κ -small, every diagram $f : K \rightarrow \mathcal{C}$ can be lifted to a diagram $f_\alpha : K \rightarrow \mathcal{C}_\alpha$ for some $\alpha \in A$ (see Variant 9.2.5.10). Using assumption (1), we see that f_α can be extended to a colimit diagram $\bar{f}_\alpha : K^\triangleright \rightarrow \mathcal{C}_\alpha$. Using assumption (2) and Proposition 9.1.9.5, we see that the image of $\bar{f}_\alpha$ in $\mathcal{C}$ is a colimit diagram $\bar{f} : K^\triangleright \rightarrow \mathcal{C}$ extending f . This proves the first assertion. Moreover, it shows that every colimit diagram in $\mathcal{C}$ can be obtained (up to isomorphism) from a colimit diagram in some $\mathcal{C}_\alpha$. Consequently, if $T : \mathcal{C} \rightarrow \mathcal{D}$ is a functor of ∞ -categories having the property that $T|_{\mathcal{C}_\alpha}$ preserves K -indexed colimits for each $\alpha \in A$, then the functor T itself preserves K -indexed colimits. The converse follows from Proposition 9.1.9.5. $\square$

Corollary 9.1.9.9. *Let κ be a small regular cardinal, let $\mathbb{K}$ be a collection of κ -small simplicial sets, and let $\mathbf{QC}^{\mathbb{K}\text{-ccomp}}$ be the subcategory of $\mathbf{QC}$ whose objects are $\mathbb{K}$ -cocomplete ∞ -categories and whose morphisms are $\mathbb{K}$ -cocontinuous functors (see Notation 7.6.6.25). Then:* 0636

- (1) The ∞ -category $\mathbf{QC}^{\mathbb{K}\text{-ccomp}}$ admits small κ -filtered colimits.
- (2) The inclusion functor $\mathbf{QC}^{\mathbb{K}\text{-ccomp}} \hookrightarrow \mathbf{QC}$ is κ -finitary: that is, it preserves small κ -filtered colimits.

Proof. Suppose we are given a diagram $\mathcal{F} : \mathcal{J} \rightarrow \mathbf{QC}^{\mathbb{K}\text{-cocont}}$, where $\mathcal{J}$ is a small κ -filtered ∞ -category. It follows from Corollary 7.4.5.3 that $\mathcal{F}$ can be extended to a colimit diagram $\bar{\mathcal{F}} : \mathcal{J}^\triangleright \rightarrow \mathbf{QC}$. Using Propositions 9.1.9.5 and 9.1.9.8, we see that any such extension factors through the subcategory $\mathbf{QC}^{\mathbb{K}\text{-cocont}} \subseteq \mathbf{QC}$, where it is also a colimit diagram. $\square$

In the situation of Corollary 9.1.9.9, it is not necessary to work with small ∞ -categories:

0637 **Variant 9.1.9.10.** Let κ be a regular cardinal and let $\mathbb{K}$ be a collection of κ -small simplicial sets. For every uncountable regular cardinal $\lambda \geq \kappa$, the ∞ -category $\mathcal{QC}_{<\lambda}^{\mathbb{K}\text{-cocont}}$ of Notation 7.6.6.25 admits λ -small κ -filtered colimits, which are preserved by the inclusion functor $\mathcal{QC}_{<\lambda}^{\mathbb{K}\text{-cocont}} \hookrightarrow \mathcal{QC}_{<\lambda}$.

0638 **Corollary 9.1.9.11.** Let $\kappa < \lambda$ be regular cardinals, where λ has exponential cofinality $\geq \kappa$. Let $\mathbb{K}$ be a collection of κ -small simplicial sets and let $T : \mathcal{QC}_{<\lambda} \rightarrow \mathcal{QC}_{<\lambda}$ be a $\mathbb{K}$ -cocompletion functor (see Definition 8.4.6.3 and Proposition 8.4.6.5). Then T is (κ, λ) -finitary: that is, it preserves λ -small κ -filtered colimits.

Proof. Let $\iota : \mathcal{QC}_{<\lambda}^{\mathbb{K}\text{-cocont}} \hookrightarrow \mathcal{QC}_{<\lambda}$ be the inclusion functor. By virtue of Proposition 8.4.6.8, the functor T factors as a composition

$$\mathcal{QC}_{<\lambda} \xrightarrow{T_0} \mathcal{QC}_{<\lambda}^{\mathbb{K}\text{-cocont}} \xrightarrow{\iota} \mathcal{QC}_{<\lambda},$$

where T_0 is left adjoint to ι and therefore preserves arbitrary colimits (Corollary 7.1.4.23). It will therefore suffice to show that the functor ι is (κ, λ) -finitary, which follows from Variant 9.1.9.10. $\square$

9.2 Finitary Functors and Compact Objects

0639 Let R be an associative ring. Recall that a (left) R -module M is *finitely presented* if it can be realized as a quotient R^n/K , where $K \subseteq R^n$ is a finitely generated submodule. This condition admits a purely categorical reformulation:

063A **Proposition 9.2.0.1.** Let R be an associative ring and let M be a left R -module. Then M is finitely presented if and only if the functor

$$\{R\text{-modules}\} \rightarrow \mathbf{Set} \quad N \mapsto \mathrm{Hom}_R(M, N)$$

preserves small filtered colimits.

Proof. Assume first that M is finitely presented: that is, there exists an exact sequence of left R -modules

$$R^m \xrightarrow{f} R^n \rightarrow M \rightarrow 0.$$

For any filtered diagram of R -modules $\{N_i\}$ having colimit N , we have a commutative diagram of exact sequences

$$\begin{array}{ccccccc} 0 & \longrightarrow & \varinjlim_i \mathrm{Hom}_R(M, N_i) & \longrightarrow & \varinjlim_i \mathrm{Hom}_R(R^n, N_i) & \longrightarrow & \varinjlim_i \mathrm{Hom}_R(R^m, N_i) \\ & & \downarrow & & \downarrow \sim & & \downarrow \sim \\ 0 & \longrightarrow & \mathrm{Hom}_R(M, N) & \longrightarrow & \mathrm{Hom}_R(R^n, N) & \longrightarrow & \mathrm{Hom}_R(R^m, N). \end{array}$$

Since the middle and right vertical maps are bijective, the left vertical map is also bijective.

We now prove the converse. Let $\{M_\alpha\}$ be the collection of all finitely generated submodules of M , partially ordered by inclusion. Then M is the colimit of the filtered diagram $\{M_\alpha\}$. If the functor $\text{Hom}_R(M, \bullet)$ preserves small filtered colimits, then the tautological map

$$\varinjlim_\alpha \text{Hom}_R(M, M_\alpha) \rightarrow \text{Hom}_R(M, M)$$

is a bijection. In particular, the identity map $\text{id}_M : M \rightarrow M$ factors through a finitely generated submodule of M , so M is generated by a finite collection of elements $x_1, x_2, \dots, x_n$. Let R^n be the free R -module on generators $\tilde{x}_1, \dots, \tilde{x}_n$, so there is surjective R -module homomorphism $f : R^n \twoheadrightarrow M$ satisfying $f(\tilde{x}_i) = x_i$ for $1 \leq i \leq n$. Let K be the kernel of f , and let $\{K_\beta\}$ be the collection of all finitely generated submodules of K , partially ordered by inclusion. If the functor $\text{Hom}_R(M, \bullet)$ preserves small filtered colimits, then the tautological map

$$\varinjlim_\beta \text{Hom}_R(M, R^n/K_\beta) \rightarrow \text{Hom}_R(M, R^n/K) = \text{Hom}_R(M, M)$$

is bijective. In particular, the identity map id_M factors as a composition

$$M \xrightarrow{g} R^n/K' \twoheadrightarrow R^n/K \simeq M,$$

where K' is some finitely generated submodule of K . Enlarging K' if necessary, we may assume that g carries each x_i to the image of $\tilde{x}_i$ in R^n/K' : that is, the composite map $g \circ f$ coincides with the tautological map from R^n to R^n/K' . We then have $K = \ker(f) \subseteq \ker(g \circ f) = K'$, so that $K = K'$ is finitely generated and $M = R^n/K$ is finitely presented. $\square$

Proposition 9.2.0.1 motivates the following:

Definition 9.2.0.2. Let $\mathcal{C}$ be a category which admits small filtered colimits. We say that 063B
an object $C \in \mathcal{C}$ is *compact* if the functor $D \mapsto \text{Hom}_{\mathcal{C}}(C, D)$ preserves small filtered colimits.

Remark 9.2.0.3. Let R be an associative ring and let $\mathcal{C}$ be the category of left R -modules. 063C
Proposition 9.2.0.1 asserts that an object $M \in \mathcal{C}$ is compact if and only if it is finitely presented as an R -module. This result has counterparts for many other classes of mathematical structures, which can be proved by the same argument:

- Let $\mathcal{C} = \text{Group}$ be the category of groups. An object $G \in \mathcal{C}$ is compact if and only if it is finitely presented as a group: that is, it can be realized as the quotient of a finitely generated free group by the normal subgroup generated by (all conjugates of) finitely many elements.
- Let $\mathcal{C} = \text{Ring}$ be the category of associative rings. Then an object $R \in \mathcal{C}$ is compact if and only if it is finitely presented as a ring: that is, it can be realized as the quotient of

a noncommutative polynomial ring $\mathbf{Z}\langle x_1, x_2, \dots, x_n \rangle$ by a finitely generated two-sided ideal.

- Let $\mathcal{C} = \mathbf{CRing}$ be the category of commutative rings. Then an object $R \in \mathcal{C}$ is compact if and only if it is finitely presented as a commutative ring: that is, it can be realized as the quotient of a finitely generated polynomial ring $\mathbf{Z}[x_1, \dots, x_n]$ by an ideal I (here I is automatically finitely generated, by virtue of the Hilbert basis theorem).

063D **Example 9.2.0.4.** Let $\mathcal{C} = \mathbf{Set}$ be the category of sets. An object $S \in \mathcal{C}$ is compact if and only if it is a finite set. See Example 9.2.5.9 for a more general statement.

063E **Variant 9.2.0.5.** Let $\mathcal{C} = \mathbf{Set}_\Delta$ be the category of simplicial sets. An object $S \in \mathcal{C}$ is compact if and only if it is a finite simplicial set, in the sense of Definition 3.6.1.1. See Proposition 3.6.1.7.

063F **Example 9.2.0.6.** Let X be a topological space and let $\mathcal{C}$ be the category of open sets of X (with morphisms given by inclusions). Then an object $U \in \mathcal{C}$ is compact if and only if U is quasi-compact when viewed as a topological space: that is, every open cover of U admits a finite subcover.

In this section, we study an ∞ -categorical counterpart of Definition 9.2.0.2. Let $\mathcal{C}$ be an ∞ -category which admits small filtered colimits. Assume for simplicity that $\mathcal{C}$ is locally small, so that every object $C \in \mathcal{C}$ corepresents a functor

$$h^C : \mathcal{C} \rightarrow \mathcal{S} \quad D \mapsto \mathrm{Hom}_{\mathcal{C}}(C, D).$$

We say that the object C is *compact* if the functor h^C preserves small filtered colimits (Definition 9.2.5.1). In §9.2.5, we introduce several variants of this condition and study their formal properties.

In practice, one can often characterize the compact objects of an ordinary category $\mathcal{C}$ as those which can be built, using finite colimits, from very simple “generators” of $\mathcal{C}$ (Remark 9.2.0.3). For this reason, many authors use the term *finitely presentable object* for what we refer to as a *compact object*. Beware that, in the setting of ∞ -categories, this terminology can be misleading. The collection of compact objects of an ∞ -category $\mathcal{C}$ is closed under both finite colimits (Corollary 9.2.5.25) and the formation of retracts (Remark 9.2.5.18). In classical category theory, the latter is a special case of the former: any retract of an object $X \in \mathcal{C}$ can be realized as the coequalizer of a pair of morphisms $(e, \mathrm{id}_X) : X \rightarrow X$ (see Corollary 8.5.2.5). In the ∞ -categorical setting, this is no longer true. Consequently, to construct a general compact object $C \in \mathcal{C}$ out of “generators”, it is often necessary to allow both finite colimits *and* retracts. In §9.2.6, we study this phenomenon in the case where $\mathcal{C} = \mathcal{S}$ is the ∞ -category of spaces. Let us say that a Kan complex X is *essentially finite* if there exists a weak homotopy equivalence $K \rightarrow X$, where K is a finite simplicial set (Definition 9.2.6.1). Then:

- A Kan complex X is essentially finite if and only if it belongs to the smallest full subcategory $\mathcal{S}_{\text{fin}} \subseteq \mathcal{S}$ which contains Δ^0 and is closed under finite colimits (Proposition 9.2.6.3).
- Every essentially finite Kan complex is compact when viewed as an object of $\mathcal{S}$ (Corollary 9.2.6.5).
- In general, an object $X \in \mathcal{S}$ is compact if and only if it can be realized as a retract of an essentially finite Kan complex (Proposition 9.2.6.7). If this condition is satisfied, we say that X is *finitely dominated* (Definition 9.2.6.6). Beware that there exist finitely dominated Kan complexes which are not essentially finite: this is the subject of the classical *Wall finiteness obstruction* (see [65]).

All of these results have counterparts where we replace $\mathcal{S}$ by the ∞ -category $\mathcal{QC}$ of (small) ∞ -categories, which we formulate and prove in §9.2.7.

Our final goal in this section is to establish some stability properties of compactness under various categorical constructions. Suppose we are given a finite diagram of ∞ -categories $\{\mathcal{C}_\alpha\}$, where each $\mathcal{C}_\alpha$ admits small filtered colimits and each of the transition functors $\mathcal{C}_\alpha \rightarrow \mathcal{C}_\beta$ is finitary. In §9.2.9, we show that an object $C = \{C_\alpha\}$ of the limit ∞ -category $\varprojlim(\mathcal{C}_\alpha)$ is compact provided that each C_α is compact as an object of $\mathcal{C}_\alpha$ (Corollary 9.2.9.2; beware that the converse is false in general). Using formal arguments, the proof reduces to the special case of diagrams of the form

$$\mathcal{C}_- \xrightarrow{F_-} \mathcal{C} \xleftarrow{F_+} \mathcal{C}_+,$$

in which case it can be regarded as an assertion about compact objects of the homotopy fiber product $\mathcal{C}_- \times_{\mathcal{C}}^h \mathcal{C}_+$. We deduce this assertion in §9.2.8 from a more general result about compact objects of an oriented fiber product $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ (see Proposition 9.2.8.1 and 9.2.8.3), which has a number of other useful consequences.

Remark 9.2.0.7. With an eye toward future applications, it will be useful to formulate the definitions and results of this section in greater generality. Suppose we are given a pair of regular cardinals $\kappa \leq \lambda$. We will say that an ∞ -category $\mathcal{C}$ is (κ, λ) -*cocomplete* if it admits colimits indexed by diagrams which are λ -small and κ -filtered (Definition 9.2.1.3). If this condition is satisfied, we say that a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is (κ, λ) -*finitary* if it preserves such colimits (Definition 9.2.2.6). We say that an object $C \in \mathcal{C}$ is (κ, λ) -*compact* if the corepresentable functor $\text{Hom}_{\mathcal{C}}(C, \bullet)$ is (κ, λ) -finitary (Definition 9.2.5.12). Following the convention of Remark 4.7.0.5, we recover the usual notion of compact object by taking $\kappa = \aleph_0$ and $\lambda = \Omega$ to be a strongly inaccessible cardinal. However, there are some other special cases worthy of note: for example, an ∞ -category $\mathcal{C}$ is $(\aleph_0, \aleph_1)$ -cocomplete if and only if it is sequentially cocomplete, in the sense of Definition 9.2.1.3 (see Corollary 9.2.3.8). 06D9

In §9.2.3, we prove more generally that an ∞ -category is (κ, κ^+) -cocomplete if and only if it admits colimits indexed by linearly ordered sets of order type κ (and a functor is (κ, κ^+) -finitary if and only if it preserves such colimits); see Proposition 9.2.3.6.

9.2.1 Filtered Cocompleteness

06DA Recall that an ∞ -category $\mathcal{C}$ is *cocomplete* if every small diagram in $\mathcal{C}$ admits a colimit (Definition 7.6.6.1). It will sometimes be helpful to break this down into two separate conditions:

06DB **Proposition 9.2.1.1.** *An ∞ -category $\mathcal{C}$ is cocomplete if and only if it satisfies both of the following conditions:*

- (a) *The ∞ -category $\mathcal{C}$ is finitely cocomplete: that is, it admits finite colimits.*
- (b) *The ∞ -category $\mathcal{C}$ admits small filtered colimits.*

Proof. Assume that conditions (a) and (b) are satisfied; we will show that $\mathcal{C}$ is cocomplete (the converse is immediate from the definitions). Let K be a small simplicial set; we wish to show that $\mathcal{C}$ admits K -indexed colimits. Let $\{K_\alpha\}_{\alpha \in A}$ be the collection of all finite simplicial subsets of K . For $\alpha, \beta \in A$, let us write $\alpha \leq \beta$ if K_α is contained in K_β . Then $(A, \leq)$ is a small directed partially ordered set, so $\mathcal{C}$ admits $N_\bullet(A)$ -indexed colimits by virtue of condition (b). It follows from condition (a) that $\mathcal{C}$ also admits K_α -indexed colimits, for each $\alpha \in A$. Applying Corollary 9.1.6.6, we conclude that $\mathcal{C}$ admits colimits indexed by $K = \varinjlim_{\alpha \in A} K_\alpha$, as desired. $\square$

06DC **Remark 9.2.1.2.** The criterion of Proposition 9.2.1.1 is quite useful in practice, because the kinds of arguments used to verify conditions (a) and (b) often have a different flavor from one another:

- To show that an ∞ -category $\mathcal{C}$ admits colimits of finite diagrams, we can reduce to the case of diagrams of very specific type: for example, $\mathcal{C}$ is finitely cocomplete if and only if it admits pushouts and has an initial object (Corollary 7.6.2.30).
- Many mathematical constructions preserve the formation of filtered colimits, but not general colimits. For this reason, it is often easy to check that some “forgetful” functor $U : \mathcal{C} \rightarrow \mathcal{D}$ creates filtered colimits (in the sense of Definition 7.1.4.18), so that the existence of filtered colimits in $\mathcal{C}$ can be reduced to existence of filtered colimits in some (potentially simpler) ∞ -category $\mathcal{D}$.

Proposition 9.2.1.1 has a counterpart for κ -cocomplete ∞ -categories, where κ is any regular cardinal. Before formulating it, it will be convenient to introduce some terminology.

Definition 9.2.1.3. Let $\kappa \leq \lambda$ be regular cardinals. We will say that an ∞ -category $\mathcal{C}$ is (κ, λ) -cocomplete if it admits $\mathcal{K}$ -indexed colimits for every ∞ -category $\mathcal{K}$ which is λ -small and κ -filtered. 06DD

Warning 9.2.1.4. Definition 9.2.1.3 makes sense for every pair of regular cardinals $\kappa \leq \lambda$. However, it is well behaved under the additional assumption $\kappa \trianglelefteq \lambda$ (see Definition 9.1.7.5). Roughly speaking, this condition guarantees that there are “enough” examples of λ -small κ -filtered ∞ -categories. 06DE

Remark 9.2.1.5 (Monotonicity). Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete. Then, for any regular cardinals $\kappa \leq \kappa' \leq \lambda' \leq \lambda$, the ∞ -category $\mathcal{C}$ is also (κ', λ') -cocomplete. 06DF

Example 9.2.1.6. Let X be a Kan complex. Then X is (κ, λ) -cocomplete when viewed as an ∞ -category, for every pair of regular cardinals $\kappa \leq \lambda$. This follows from Corollary 7.2.3.5, since every filtered ∞ -category is weakly contractible (Proposition 9.1.1.17). 06DG

Proposition 9.2.1.7. Let κ and λ be regular cardinals satisfying $\kappa \trianglelefteq \lambda$. For every ∞ -category $\mathcal{C}$, the following conditions are equivalent: 062W

- (1) The ∞ -category $\mathcal{C}$ is λ -cocomplete.
- (2) The ∞ -category $\mathcal{C}$ is both κ -cocomplete and (κ, λ) -cocomplete.

Remark 9.2.1.8. Following the convention of Remark 4.7.0.5, Proposition 9.2.1.1 can be viewed as a special case where of Proposition 9.2.1.7, where we take $\kappa = \aleph_0$ and $\lambda = \Omega$ to be a strongly inaccessible cardinal. 06DH

Proof of Proposition 9.2.1.7. The implication (1) $\Rightarrow$ (2) is trivial (and does not require the assumption $\kappa \trianglelefteq \lambda$). To prove the converse, we proceed as in the proof of Proposition 9.2.1.1. Assume that $\mathcal{C}$ is both κ -cocomplete and (κ, λ) -cocomplete; we wish to show that every λ -small diagram $K \rightarrow \mathcal{C}$ admits a colimit. Using Lemma 9.1.7.18, we can realize K as the colimit of a diagram of κ -small simplicial subsets $\{K_\alpha\}_{\alpha \in A}$ indexed by a λ -small κ -directed partially ordered set $(A, \leq)$. Since $\mathcal{C}$ is κ -cocomplete, it admits K_α -indexed colimits for each $\alpha \in A$. Our assumption that $\mathcal{C}$ is (κ, λ) -cocomplete guarantees that it also admits $N_\bullet(A)$ -indexed colimits. Applying Corollary 9.1.6.6, we conclude that $\mathcal{C}$ admits colimits indexed by $K = \varinjlim_{\alpha \in A} K_\alpha$, as desired. $\square$

Corollary 9.2.1.9. Let κ be a small regular cardinal. Then an ∞ -category $\mathcal{C}$ is cocomplete if and only if it is κ -cocomplete and admits small κ -filtered colimits. 03DK

Proof. Apply Proposition 9.2.1.7 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal (see Example 9.1.7.11). $\square$

06DJ **Corollary 9.2.1.10.** *Let λ be a regular cardinal. Then an ∞ -category $\mathcal{C}$ is λ -cocomplete if and only if it is finitely cocomplete and admits λ -small filtered colimits.*

Proof. Apply Proposition 9.2.1.7 in the special case where $\kappa = \aleph_0$ (see Example 9.1.7.10). $\square$

Definition 9.2.1.3 can often be simplified.

062K **Proposition 9.2.1.11.** *Let κ and λ be regular cardinals satisfying $\kappa \triangleleft \lambda$. For every ∞ -category $\mathcal{C}$, the following conditions are equivalent:*

- (1) *The ∞ -category $\mathcal{C}$ is (κ, λ) -cocomplete.*
- (2) *The ∞ -category $\mathcal{C}$ admits $N_\bullet(A)$ -indexed colimits, for every λ -small κ -directed partially ordered set $(A, \leq)$.*

Proof. The implication (1) $\Rightarrow$ (2) follows from Example 9.1.1.7, and the reverse implication follows by combining Theorem 9.1.8.7 with Corollary 7.2.2.12. $\square$

062M **Corollary 9.2.1.12.** *Let κ be a small regular cardinal. Then an ∞ -category $\mathcal{C}$ admits small κ -filtered colimits if and only if it admits $N_\bullet(A)$ -indexed colimits, for every small κ -directed partially ordered set $(A, \leq)$.*

Proof. Apply Proposition 9.2.1.11 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal (see Example 9.1.7.11). $\square$

039G **Corollary 9.2.1.13.** *Let λ be an uncountable regular cardinal. Then ∞ -category $\mathcal{C}$ admits λ -small filtered colimits if and only if it admits $N_\bullet(A)$ -indexed colimits, for every λ -small directed partially ordered set $(A, \leq)$.*

Proof. Apply Proposition 9.2.1.11 in the special case $\kappa = \aleph_0$ (see Example 9.1.7.10). $\square$

Beware that Proposition 9.2.1.11 is not quite correct in the degenerate case $\kappa = \lambda$. Instead we have the following:

062R **Proposition 9.2.1.14.** *Let κ be a regular cardinal. Then:*

- *If κ is uncountable, then an ∞ -category $\mathcal{C}$ is (κ, κ) -cocomplete if and only if it is idempotent-complete.*
- *If $\kappa = \aleph_0$, then every ∞ -category is (κ, κ) -cocomplete.*

Proof. We will assume that κ is uncountable (the case $\kappa = \aleph_0$ follows from Corollary 9.1.8.12). In this case, the ∞ -category $N_\bullet(\text{Idem})$ of Construction 8.5.2.7 is both κ -small and κ -filtered (Example 9.1.1.9), so every (κ, κ) -cocomplete ∞ -category is idempotent-complete (Proposition 8.5.4.9). Conversely, suppose that $\mathcal{C}$ is idempotent-complete; we wish to show

that $\mathcal{C}$ admits $\mathcal{K}$ -indexed colimits for every ∞ -category $\mathcal{K}$ which is both κ -small and κ -filtered. Proposition 9.1.8.11 guarantees the existence of a right cofinal functor $\mathbf{N}_\bullet(\text{Idem}) \rightarrow \mathcal{K}$, so the desired result follows from Corollary 7.2.2.12. $\square$

Proposition 9.2.1.15 (Transitivity). *Let κ , λ , and μ be regular cardinals satisfying $\kappa \trianglelefteq \lambda \trianglelefteq \mu$. Then an ∞ -category $\mathcal{C}$ is (κ, μ) -cocomplete if and only if it is both (κ, λ) -cocomplete and (λ, μ) -cocomplete.* 06DK

Proof. We will assume $\kappa < \lambda$ (otherwise, there is nothing to prove). Assume that $\mathcal{C}$ is (κ, λ) -cocomplete and (λ, μ) -cocomplete; we wish to show that it is (κ, μ) -cocomplete (the converse follows immediately from Remark 9.2.1.5, and requires only the assumption $\kappa \leq \lambda \leq \mu$). This follows from Corollary 9.1.6.6, since every μ -small κ -filtered ∞ -category $\mathcal{K}$ can be realized as a μ -small, λ -filtered colimit of λ -small κ -filtered ∞ -categories (Corollary 9.1.7.16). $\square$

Corollary 9.2.1.16. *Let κ and λ be small regular cardinals satisfying $\kappa \trianglelefteq \lambda$. Then an ∞ -category $\mathcal{C}$ admits small κ -filtered colimits if and only if it admits small λ -filtered colimits and is (κ, λ) -cocomplete.* 06DL

Proof. Apply Proposition 9.2.2.29 in the special case where $\lambda = \Omega$ is a fixed strongly inaccessible cardinal (see Example 9.1.7.11). $\square$

Corollary 9.2.1.17. *Let λ be a small regular cardinal. Then an ∞ -category $\mathcal{C}$ admits small λ -filtered colimits if and only if it admits small λ -filtered colimits and λ -small filtered colimits.* 06DM

Proof. Apply Corollary 9.2.1.16 in the special case $\kappa = \aleph_0$ (see Example 9.1.7.10). $\square$

9.2.2 Finitary Functors

We now study colimits indexed by filtered ∞ -categories. 062B

Definition 9.2.2.1. Let $\mathcal{C}$ and $\mathcal{D}$ be ∞ -categories, where $\mathcal{C}$ admits small filtered colimits. We say that a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is *finitary* if F preserves $\mathcal{K}$ -indexed colimits, for every small filtered ∞ -category $\mathcal{K}$. We let $\text{Fun}^{\text{fin}}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by the finitary functors from $\mathcal{C}$ to $\mathcal{D}$. 039F

Remark 9.2.2.2. We will primarily make use of Definition 9.2.2.1 in situations where the ∞ -category $\mathcal{D}$ also admits small filtered colimits. 062C

We will often use an infinitary version of Definition 9.2.2.1.

Definition 9.2.2.3. Let κ be a small regular cardinal, let $\mathcal{C}$ be an ∞ -category which admits small κ -filtered colimits, and let $\mathcal{D}$ be another ∞ -category. We say that a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is *κ -finitary* if it preserves $\mathcal{K}$ -indexed colimits, for every small κ -filtered ∞ -category $\mathcal{K}$. We let $\text{Fun}^{\kappa\text{-fin}}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by the κ -finitary functors from $\mathcal{C}$ to $\mathcal{D}$. 05Y6

062D **Remark 9.2.2.4.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, where $\mathcal{C}$ admits small filtered colimits. Then F is finitary (in the sense of Definition 9.2.2.3) if and only if it is $\aleph_0$ -finitary (in the sense of Definition 9.2.2.3).

062E **Example 9.2.2.5.** If K is a κ -small simplicial set, then the limit functor $\varprojlim : \text{Fun}(K, \mathcal{S}) \rightarrow \mathcal{S}$ is κ -finitary: this is a reformulation of Theorem 9.1.5.9 (see Proposition 7.7.7.1). In particular, if K is a finite simplicial set, then the functor $\varprojlim : \text{Fun}(K, \mathcal{S}) \rightarrow \mathcal{S}$ is finitary.

It will sometimes be useful to consider a further generalization of Definition 9.2.2.1.

062F **Definition 9.2.2.6.** Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete. We say that a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is (κ, λ) -finitary if it preserves $\mathcal{K}$ -indexed colimits, for every ∞ -category $\mathcal{K}$ which is λ -small and κ -filtered. We let $\text{Fun}^{(\kappa, \lambda)\text{-fin}}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by the (κ, λ) -finitary functors from $\mathcal{C}$ to $\mathcal{D}$.

062G **Warning 9.2.2.7.** Definition 9.2.2.6 makes sense for every pair of regular cardinals $\kappa \leq \lambda$. However, we will mostly be interested in the case where $\kappa \leq \lambda$, in the sense of Definition 9.1.7.5 (compare with Warning 9.2.1.4).

062S **Remark 9.2.2.8** (Monotonicity). Let $\kappa \leq \lambda$ be regular cardinals, let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Assume that $\mathcal{C}$ is (κ, λ) -cocomplete and that F is (κ, λ) -finitary. Then the functor F is also (κ', λ') -finitary, for any regular cardinals $\kappa \leq \kappa' \leq \lambda' \leq \lambda$ (compare with Remark 9.2.1.5).

06DN **Example 9.2.2.9.** Let $\kappa \leq \lambda$ be regular cardinals and let $F : \mathcal{C} \rightarrow \mathcal{D}$ is an equivalence of ∞ -categories. Then $\mathcal{C}$ is (κ, λ) -cocomplete if and only if $\mathcal{D}$ is (κ, λ) -cocomplete. If these conditions are satisfied, then F is automatically (κ, λ) -finitary.

In particular, for every (κ, λ) -cocomplete ∞ -category $\mathcal{C}$, the identity functor $\text{id}_{\mathcal{C}}$ is (κ, λ) -finitary.

06DP **Remark 9.2.2.10** (Composition). Let $\kappa \leq \lambda$ be regular cardinals and let $F : \mathcal{C} \rightarrow \mathcal{D}$ and $G : \mathcal{D} \rightarrow \mathcal{E}$ be functors of ∞ -categories. Assume that $\mathcal{C}$ and $\mathcal{D}$ are (κ, λ) -cocomplete and that F and G are (κ, λ) -finitary. Then the composite functor $(G \circ F) : \mathcal{C} \rightarrow \mathcal{E}$ is also (κ, λ) -finitary.

06DQ **Example 9.2.2.11.** Let $\kappa \leq \lambda$ be regular cardinals and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, where $\mathcal{C}$ is (κ, λ) -cocomplete. If either $\mathcal{C}$ or $\mathcal{D}$ is a Kan complex, then F is automatically (κ, λ) -finitary. See Example 7.2.3.5.

06DR **Example 9.2.2.12.** Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete, and let $\mathcal{D}$ be an ∞ -category containing an object D . Then the constant functor $\mathcal{C} \rightarrow \{D\} \hookrightarrow \mathcal{D}$ is (κ, λ) -finitary. This follows by combining Remark 9.2.2.10 with Example 9.2.2.11 (since $\{D\}$ is a Kan complex). In particular, the inclusion functor $\{D\} \hookrightarrow \mathcal{D}$ is always (κ, λ) -finitary.

Remark 9.2.2.13 (Retracts). Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete, and let $\mathcal{D}$ be another ∞ -category. Suppose we are given a pair of functors $F, G : \mathcal{C} \rightarrow \mathcal{D}$, where F is a retract of G (in the ∞ -category $\text{Fun}(\mathcal{C}, \mathcal{D})$). If G is (κ, λ) -finitary, then F is also (κ, λ) -finitary (see Corollary 8.5.1.12). In particular, the condition that a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is (κ, λ) -finitary depends only on the isomorphism class of F . 06DS

Notation 9.2.2.14. Let $\mathcal{QC}$ denote the ∞ -category of (small) ∞ -categories (Construction 5.5.4.1). For every pair of regular cardinals $\kappa \leq \lambda$, we define a subcategory $\mathcal{QC}^{(\kappa, \lambda)\text{-ccomp}} \subseteq \mathcal{QC}$ as follows: 06DT

- An object $\mathcal{C}$ of $\mathcal{QC}$ belongs to $\mathcal{QC}^{(\kappa, \lambda)\text{-ccomp}}$ if and only if it is a (κ, λ) -cocomplete ∞ -category, in the sense of Definition 9.2.1.3.
- A morphism $F : \mathcal{C} \rightarrow \mathcal{D}$ of $\mathcal{QC}$ belongs to $\mathcal{QC}^{(\kappa, \lambda)\text{-ccomp}}$ if and only if it is a (κ, λ) -finitary functor, in the sense of Definition 9.2.2.6.

More generally, if μ is any uncountable cardinal, we let $\mathcal{QC}_{<\mu}^{(\kappa, \lambda)\text{-ccomp}}$ denote the subcategory of $\mathcal{QC}_{<\mu}$ whose objects are μ -small ∞ -categories which are (κ, λ) -cocomplete, and whose morphisms are (κ, λ) -finitary functors. In practice, we will be primarily interested in the case where μ is much larger than λ (so that there are plenty of examples of such ∞ -categories).

Remark 9.2.2.15. Following the convention of Remark 4.7.0.5, a cardinal κ is small if it satisfies $\kappa < \Omega$, where Ω is some fixed strongly inaccessible cardinal. In this case, a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is κ -finitary (in the sense of Definition 9.2.2.3) if and only if it is (κ, Ω) -finitary (in the sense of Definition 9.2.2.6). Note that in this case we automatically have $\kappa \triangleleft \Omega$ (Example 9.1.7.11). In particular, F is finitary if and only if it is $(\aleph_0, \Omega)$ -finitary. 062H

Example 9.2.2.16. Let κ be a regular cardinal and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Assume either that $\mathcal{C}$ is idempotent-complete or that $\kappa = \aleph_0$, so that $\mathcal{C}$ is (κ, κ) -cocomplete (Proposition 9.2.1.14). Then F is automatically (κ, κ) -finitary: that is, it preserves $\mathcal{K}$ -indexed colimits for every ∞ -category $\mathcal{K}$ which is both κ -small and κ -filtered. For $\kappa = \aleph_0$, this follows from Corollary 9.1.8.12. If κ is uncountable, we can use Proposition 9.1.8.11 to reduce to the case $\mathcal{K} = \mathbf{N}_\bullet(\text{Idem})$, in which case the desired result is automatic (Corollary 8.5.3.12). 06DU

Remark 9.2.2.17. Let $\kappa \leq \lambda$ be regular cardinals, and let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete. Let μ be an uncountable cardinal having cofinality $\geq \lambda$ and exponential cofinality $\geq \kappa$, so that the ∞ -category $\mathcal{S}_{<\mu}$ admits λ -small colimits and κ -small limits (see Corollary 7.4.3.8 and Variant 7.4.1.15). Then the ∞ -category $\text{Fun}^{(\kappa, \lambda)\text{-fin}}(\mathcal{C}, \mathcal{S}_{<\mu})$ is closed under the formation of κ -small limits in $\text{Fun}(\mathcal{C}, \mathcal{S}_{<\mu})$. See Proposition 9.1.5.10 (and Proposition 7.7.7.1). In particular: 062J

- If κ is small and $\mathcal{C}$ admits small κ -filtered colimits, then the collection of κ -finitary functors $\mathcal{C} \rightarrow \mathcal{S}$ is closed under κ -small limits.
- If $\mathcal{C}$ admits small filtered colimits, then the collection of finitary functors $\mathcal{C} \rightarrow \mathcal{S}$ is closed under finite limits.

062N **Example 9.2.2.18.** Let $\mathbf{Kan}$ denote the ordinary category of Kan complexes and let $\mathcal{S}$ denote the ∞ -category of spaces. Then the inclusion functor

$$N_{\bullet}(\mathbf{Kan}) \hookrightarrow N_{\bullet}^{\mathrm{hc}}(\mathbf{Kan}) = \mathcal{S}$$

is finitary: this follows by combining Corollary 9.2.1.13 with Variant 9.1.6.4. More generally, if λ is an uncountable regular cardinal and $\mathbf{Kan}_{<\lambda}$ denote the category of λ -small Kan complexes, then the inclusion functor $N_{\bullet}(\mathbf{Kan}_{<\lambda}) \hookrightarrow N_{\bullet}^{\mathrm{hc}}(\mathbf{Kan}_{<\lambda}) = \mathcal{S}_{<\lambda}$ is $(\aleph_0, \lambda)$ -finitary: that is, it preserves λ -small filtered colimits.

062P **Example 9.2.2.19.** The inclusion functor $N_{\bullet}(\mathbf{Set}) \hookrightarrow \mathcal{S}$ is finitary (see Variant 9.1.6.4). For a more general statement, see Variant 9.1.9.3.

062Q **Example 9.2.2.20.** Let $\mathbf{QCat}$ denote the full subcategory of $\mathbf{Set}_{\Delta}$ spanned by the ∞ -categories, and let $\mathcal{QC} = N_{\bullet}^{\mathrm{hc}}(\mathbf{QCat})$ be its homotopy coherent nerve (see Construction 5.5.4.1). Then the inclusion functor

$$N_{\bullet}(\mathbf{QCat}) \hookrightarrow N_{\bullet}^{\mathrm{hc}}(\mathbf{QCat}) = \mathcal{QC}$$

is finitary: this follows by combining Corollary 9.2.1.13 with Corollary 9.1.6.3. More generally, if λ is an uncountable regular cardinal and $\mathbf{QCat}_{<\lambda}$ denote the category of λ -small ∞ -categories, then the inclusion functor $N_{\bullet}(\mathbf{QCat}_{<\lambda}) \hookrightarrow N_{\bullet}^{\mathrm{hc}}(\mathbf{QCat}_{<\lambda}) = \mathcal{QC}_{<\lambda}$ is $(\aleph_0, \lambda)$ -finitary.

Many of the results of §9.2.1 regarding (κ, λ) -cocomplete ∞ -categories have counterparts for (κ, λ) -finitary functors.

06DV **Proposition 9.2.2.21.** *Let $\kappa \trianglelefteq \lambda$ be regular cardinals and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, where $\mathcal{C}$ is λ -cocomplete. The following conditions are equivalent:*

- (1) *The functor F is λ -cocontinuous: that is, it preserves λ -small colimits.*
- (2) *The functor F is both κ -cocontinuous and (κ, λ) -finitary.*

Proof. The implication (1) $\Rightarrow$ (2) is trivial (and does not require the assumption $\kappa \trianglelefteq \lambda$). For the converse, suppose that condition (2) is satisfied. We wish to show that the functor F preserves K -indexed colimits for every λ -small simplicial set K . Using Lemma 9.1.7.18, we can realize K as the colimit of a diagram of κ -small simplicial subsets $\{K_{\alpha}\}_{\alpha \in A}$ indexed by a

λ -small κ -directed partially ordered set $(A, \leq)$. If F is κ -cocontinuous, then it preserves K_α -indexed colimits for each index $\alpha \in A$. Our assumption that F is (κ, λ) -finitary guarantees that it also admits $N_\bullet(A)$ -indexed colimits. Applying Corollary 9.1.6.6, we conclude that F preserves colimits indexed by the filtered colimit $K = \varinjlim_{\alpha \in A} K_\alpha$. $\square$

Corollary 9.2.2.22. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, where $\mathcal{C}$ is cocomplete, and let κ be a small regular cardinal. Then F is cocontinuous if and only if it is κ -cocontinuous and κ -finitary.* 06DW

Proof. Apply Proposition 9.2.2.21 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal (see Example 9.1.7.11). $\square$

Corollary 9.2.2.23. *Let λ be a regular cardinal and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, where $\mathcal{C}$ is λ -cocomplete. Then F is λ -cocontinuous if and only if it is finitely cocontinuous and preserves λ -small filtered colimits.* 06DX

Proof. Apply Proposition 9.2.1.7 in the special case where $\kappa = \aleph_0$ (see Example 9.1.7.10). $\square$

Corollary 9.2.2.24. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, where $\mathcal{C}$ is cocomplete. Then F is cocontinuous if and only if it is finitely cocontinuous and finitary.* 06DY

Proof. Apply Corollary 9.2.2.22 in the special case $\kappa = \aleph_0$. $\square$

Proposition 9.2.2.25. *Let κ and λ be regular cardinals satisfying $\kappa \leq \lambda$. For every ∞ -category $\mathcal{C}$, the following conditions are equivalent:* 06DZ

- (1) *The ∞ -category $\mathcal{C}$ is (κ, λ) -cocomplete.*
- (2) *The ∞ -category $\mathcal{C}$ admits $N_\bullet(A)$ -indexed colimits, for every λ -small κ -directed partially ordered set $(A, \leq)$.*

Proof. The implication (1) $\Rightarrow$ (2) follows from Example 9.1.1.7. To prove the converse, we may assume that $\kappa < \lambda$ (otherwise there is nothing to prove, by virtue of Example 9.2.2.16). In this case, the desired result follows from Corollary 7.2.2.8, since every λ -small κ -filtered ∞ -category $\mathcal{K}$ admits a right cofinal functor $N_\bullet(A) \rightarrow \mathcal{K}$, where $(A, \leq)$ is a λ -small κ -directed partially ordered set (Theorem 9.1.8.7). $\square$

Corollary 9.2.2.26. *Let κ be a small regular cardinal and let $\mathcal{C}$ be an ∞ -category which admits small κ -filtered colimits. Then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is κ -finitary if and only if it preserves $N_\bullet(A)$ -indexed colimits, for every small κ -directed partially ordered set $(A, \leq)$.* 06E0

Proof. Apply Proposition 9.2.2.25 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal (see Example 9.1.7.11). $\square$

06E1 **Corollary 9.2.2.27.** *Let λ be a regular cardinal and let $\mathcal{C}$ be an ∞ -category which admits λ -small filtered colimits. Then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ preserves λ -small filtered colimits if and only if it preserves $N_\bullet(A)$ -indexed colimits, for every λ -small directed partially ordered set $(A, \leq)$.*

Proof. Apply Proposition 9.2.2.25 in the special case $\kappa = \aleph_0$ (see Example 9.1.7.10). $\square$

06E2 **Corollary 9.2.2.28.** *Let $\mathcal{C}$ be an ∞ -category which admits small filtered colimits. Then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is finitary if and only if it preserves $N_\bullet(A)$ -indexed colimits, for every small directed partially ordered set $(A, \leq)$.*

Proof. Apply Corollary 9.2.2.26 in the special case $\kappa = \aleph_0$. $\square$

062T **Proposition 9.2.2.29** (Transitivity). *Let $\kappa \leq \lambda \leq \mu$ be regular cardinals and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, where $\mathcal{C}$ is (κ, μ) -cocomplete. The following conditions are equivalent:*

- (1) *The functor F is (κ, μ) -finitary.*
- (2) *The functor F is (κ, λ) -finitary and (λ, μ) -finitary.*

Proof. We will assume that $\kappa < \lambda$ (otherwise, there is nothing to prove). The implication (1) $\Rightarrow$ (2) follows from Remark 9.2.2.8 (and requires only the assumption $\kappa \leq \lambda \leq \mu$). The converse follows from Corollary 9.1.6.6, since every μ -small κ -filtered ∞ -category $\mathcal{K}$ can be realized as a μ -small, λ -filtered colimit of λ -small κ -filtered ∞ -categories (Corollary 9.1.7.16). $\square$

062U **Corollary 9.2.2.30.** *Let κ and λ be small regular cardinals satisfying $\kappa \leq \lambda$ and let $\mathcal{C}$ be an ∞ -category which admits small κ -filtered colimits. Then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is κ -finitary if and only if it is both λ -finitary and (κ, λ) -finitary.*

Proof. Apply Proposition 9.2.2.29 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal (see Example 9.1.7.11). $\square$

062V **Corollary 9.2.2.31.** *Let λ be a small regular cardinal and let $\mathcal{C}$ be an ∞ -category which admits small filtered colimits. Then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is finitary if and only if it is λ -finitary and preserves λ -small filtered colimits.*

Proof. Apply Corollary 9.2.2.30 in the special case $\kappa = \aleph_0$ (see Example 9.1.7.10). $\square$

9.2.3 Example: Sequential Cocompleteness

Recall that an ∞ -category $\mathcal{C}$ is *sequentially cocomplete* if every diagram

06E3

$$X_0 \rightarrow X_1 \rightarrow X_2 \rightarrow \cdots$$

admits a colimit in $\mathcal{C}$ (Definition 7.6.5.1). In this section, we study a transfinite variant of this condition.

Definition 9.2.3.1. Let κ be a regular cardinal. We say that an ∞ -category $\mathcal{C}$ is κ -*sequentially cocomplete* if it admits $N_\bullet(\text{Ord}_{<\kappa})$ -indexed colimits. Here $\text{Ord}_{<\kappa}$ denotes the collection of ordinals which are strictly smaller than κ (so that $\text{Ord}_{<\kappa}$ is a linearly ordered set of order type κ : see Proposition 4.7.1.22). If this condition is satisfied, then we say that a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ *preserves κ -sequential colimits* if it preserves $N_\bullet(\text{Ord}_{<\kappa})$ -indexed colimits. 06E4

Example 9.2.3.2. An ∞ -category $\mathcal{C}$ is sequentially cocomplete (in the sense of Definition 7.6.5.1) if and only if it is $\aleph_0$ -sequentially cocomplete (in the sense of Definition 9.2.3.1). If this condition is satisfied, then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ preserves sequential colimits if and only if it preserves $\aleph_0$ -sequential colimits. 06E5

Warning 9.2.3.3. Let κ be a regular cardinal. There is a slight tension between the terminological conventions of Definitions 7.6.6.6 and Definition 9.2.3.1: 06E6

- According to Definition 7.6.6.6, an ∞ -category $\mathcal{C}$ is κ -cocomplete if it admits K -indexed colimits for every κ -small simplicial set K .
- According to Definition 9.2.3.1, an ∞ -category $\mathcal{C}$ is κ -sequentially cocomplete if it admits colimits indexed by the ∞ -category $N_\bullet(\text{Ord}_{<\kappa})$.

Neither of these conditions implies the other (the linearly ordered set $\text{Ord}_{<\kappa}$ has cardinality κ , and is therefore not κ -small). Instead, they should be viewed as complementary to one another: see Corollary 9.2.3.9.

Notation 9.2.3.4. Let $\mathcal{QC}$ denote the ∞ -category of (small) ∞ -categories (Construction 5.5.4.1). For every regular cardinal κ , we define a subcategory $\mathcal{QC}^{\kappa\text{-seq}} \subseteq \mathcal{QC}$ as follows: 06E7

- An object $\mathcal{C}$ of $\mathcal{QC}$ belongs to $\mathcal{QC}^{\kappa\text{-seq}}$ if and only if it is κ -sequentially cocomplete.
- A morphism $F : \mathcal{C} \rightarrow \mathcal{D}$ of $\mathcal{QC}$ belongs to $\mathcal{QC}^{\kappa\text{-seq}}$ if and only if it preserves κ -sequential colimits, in the sense of Definition 9.2.2.6.

More generally, if λ is any uncountable cardinal, we let $\mathcal{QC}_{<\lambda}^{\kappa\text{-seq}}$ denote the subcategory of $\mathcal{QC}_{<\lambda}$ whose objects are λ -small ∞ -categories which are κ -sequentially cocomplete, and whose morphisms are functors which preserve κ -sequential colimits.

To formulate Definition 9.2.3.1 it is not necessary to assume that κ is regular, or even that it is a cardinal. However, this does not really lead to any additional generality:

06E8 Proposition 9.2.3.5. *Let $(Q, \leq)$ be a nonempty linearly ordered set with no largest element, so that the cofinality $\kappa = \text{cf}(Q)$ is a regular cardinal (Example 4.7.3.15). Then an ∞ -category $\mathcal{C}$ is κ -sequentially cocomplete (in the sense of Definition 9.2.3.1) if and only if it admits $N_\bullet(Q)$ -indexed colimits. If this condition is satisfied, then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is κ -sequentially cocontinuous if and only if it preserves $N_\bullet(Q)$ -indexed colimits.*

Proof. Recall that the cofinality $\kappa = \text{cf}(Q)$ is characterized by the requirement that there exists a cofinal map of linearly ordered sets $f : \text{Ord}_{<\kappa} \rightarrow Q$. Then, for each $q \in Q$, there exists an ordinal $\alpha < \kappa$ satisfying $q \leq f(\alpha)$. Let $g(q)$ be the smallest such ordinal, so that the construction $q \mapsto g(q)$ determines a cofinal map of linearly ordered sets $g : Q \rightarrow \text{Ord}_{<\kappa}$. Invoking Corollary 7.2.3.4, we deduce that the functors

$$N_\bullet(f) : N_\bullet(\text{Ord}_{<\kappa}) \rightarrow N_\bullet(Q) \quad N_\bullet(g) : N_\bullet(Q) \rightarrow N_\bullet(\text{Ord}_{<\kappa})$$

are right cofinal. The desired results now follow from Corollaries 7.2.2.12 and 7.2.2.8. $\square$

Definition 9.2.3.1 can be viewed as a special case of Definition 9.2.1.3:

06E9 Proposition 9.2.3.6. *Let κ be a regular cardinal and let $\mathcal{C}$ be an ∞ -category. Then following conditions are equivalent:*

- (1) *The ∞ -category $\mathcal{C}$ is κ -sequentially cocomplete (in the sense of Definition 9.2.3.1).*
- (2) *The ∞ -category $\mathcal{C}$ is (κ, κ^+) -cocomplete (in the sense of Definition 9.2.1.3), where κ^+ is the successor of κ .*

Proof. The implication (2) $\Rightarrow$ (1) is immediate, since the ∞ -category $N_\bullet(\text{Ord}_{<\kappa})$ is κ^+ -small and κ -filtered (Example 9.1.1.8). The converse follows from Corollary 7.2.2.12, since every κ^+ -small κ -filtered ∞ -category $\mathcal{K}$ admits a right cofinal functor $N_\bullet(\text{Ord}_{<\kappa}) \rightarrow \mathcal{K}$ (Corollary 9.1.8.9). $\square$

06EA Remark 9.2.3.7. In the situation of Proposition 9.2.3.6, a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ preserves κ -sequential colimits (in the sense of Definition 9.2.3.1) if and only if it is (κ, κ^+) -finitary (in the sense of Definition 9.2.2.6). In other words, we have an equality $\mathcal{QC}^{\kappa\text{-seq}} = \mathcal{QC}^{(\kappa, \kappa^+)\text{-ccomp}}$ of subcategories of $\mathcal{QC}$ (see Notations 9.2.3.4 and 9.2.2.14).

06EB Corollary 9.2.3.8. *An ∞ -category $\mathcal{C}$ is $(\aleph_0, \aleph_1)$ -cocomplete (in the sense of Definition 9.2.1.3) if and only if it is sequentially cocomplete (in the sense of Definition 7.6.5.1). If these conditions are satisfied, then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is $(\aleph_0, \aleph_1)$ -finitary if and only if it preserves sequential colimits.*

Proof. Apply Proposition 9.2.3.6 (and Remark 9.2.3.7) in the special case $\kappa = \aleph_0$ (see Example 9.2.3.2). $\square$

Corollary 9.2.3.9. *Let κ be a regular cardinal. Then an ∞ -category $\mathcal{C}$ is κ^+ -cocomplete if and only if it is both κ -cocomplete and κ -sequentially cocomplete. If these conditions are satisfied, then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is κ^+ -cocontinuous if and only if it is κ -cocontinuous and preserves κ -sequential colimits.* 06EC

Proof. Combine Proposition 9.2.3.6 with Proposition 9.2.1.7 (for the first assertion) and Proposition 9.2.2.21 (for the second). $\square$

Corollary 9.2.3.10. *Let $\mathcal{C}$ be an ∞ -category. Then $\mathcal{C}$ is $\aleph_1$ -cocomplete (that is, it admits countable colimits) if and only if it is finitely cocomplete and sequentially cocomplete. If these conditions are satisfied, then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is $\aleph_1$ -cocontinuous (that is, it preserves countable colimits) if and only if it preserves finite colimits and sequential colimits.* 06ED

Proof. Apply Corollary 9.2.3.9 in the special case $\kappa = \aleph_0$ (see Example 9.2.3.2). $\square$

Corollary 9.2.3.11. *Let κ be a small regular cardinal and let $\mathcal{C}$ be an ∞ -category. Then $\mathcal{C}$ admits small κ -filtered colimits if and only if it admits small κ^+ -filtered colimits and is κ -sequentially cocomplete. If these conditions are satisfied, then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is κ -finitary if and only if it is κ^+ -finitary and preserves κ -sequential colimits.* 06EE

Proof. Combine Proposition 9.2.3.6 with Corollary 9.2.1.16 (for the first assertion) and Corollary 9.2.2.30 (for the second). $\square$

Corollary 9.2.3.12. *Let $\mathcal{C}$ be an ∞ -category. Then $\mathcal{C}$ admits small filtered colimits if and only if it is sequentially cocomplete and admits small $\aleph_1$ -filtered colimits. If these conditions are satisfied, then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is finitary if and only if it is $\aleph_1$ -finitary and preserves sequential colimits.* 06EF

Proof. Apply Corollary 9.2.3.11 in the special case $\kappa = \aleph_0$. $\square$

9.2.4 Fiber Products of Filtered ∞ -Categories

Let $\mathcal{C}_-$, $\mathcal{C}_+$, and $\mathcal{C}$ be filtered ∞ -categories, and suppose we are given functors $F_- : \mathcal{C}_- \rightarrow \mathcal{C}$ and $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$. If F_- and F_+ are cocartesian fibrations, then Corollary 9.1.3.14 guarantees that the fiber product $\mathcal{C}_- \times_{\mathcal{C}} \mathcal{C}_+$ is also a filtered ∞ -category. Our goal in this section is to prove a variant of this result, where we relax the assumption that F_- and F_+ are cocartesian fibrations. 06EG

06EH **Proposition 9.2.4.1.** *Suppose we are given a categorical pullback diagram of ∞ -categories*

06EJ

$$\begin{array}{ccc} \mathcal{C}_{\pm} & \xrightarrow{E_+} & \mathcal{C}_+ \\ \downarrow E_- & & \downarrow F_+ \\ \mathcal{C}_- & \xrightarrow{F_-} & \mathcal{C} \end{array} \quad (9.3)$$

satisfying the following conditions:

- (1) *The ∞ -categories $\mathcal{C}_-$, $\mathcal{C}$, and $\mathcal{C}_+$ are filtered.*
- (2) *The functors F_- and F_+ are right cofinal.*
- (3) *The ∞ -categories $\mathcal{C}_-$ and $\mathcal{C}_+$ are sequentially cocomplete, and the functors F_- and F_+ preserve sequential colimits.*

Then the ∞ -category $\mathcal{C}_{\pm}$ is filtered, and the functors E_- and E_+ are right cofinal.

06EK **Warning 9.2.4.2.** In the formulation of Proposition 9.2.4.1, condition (3) cannot be omitted. For example, let $\mathcal{C} = \mathbf{N}_{\bullet}(\mathbf{Z})$ be the nerve of the linearly ordered set of integers $\mathbf{Z} = \{\cdots < -2 < -1 < 0 < 1 < 2 < \cdots\}$, let $\mathcal{C}_+$ be the full subcategory of $\mathcal{C}$ spanned by the even integers, and let $\mathcal{C}_-$ be the full subcategory of $\mathcal{C}$ spanned by the odd integers. Then the ∞ -categories $\mathcal{C}_-$, $\mathcal{C}$, and $\mathcal{C}_+$ are filtered (Example 9.1.1.2), and the inclusion functors $F_- : \mathcal{C}_- \hookrightarrow \mathcal{C}$ and $F_+ : \mathcal{C}_+ \hookrightarrow \mathcal{C}$ are right cofinal (Corollary 7.2.3.4). However, the fiber product $\mathcal{C}_- \times_{\mathcal{C}} \mathcal{C}_+$ (which coincides with the homotopy fiber product $\mathcal{C}_- \times_{\mathcal{C}}^{\mathbf{h}} \mathcal{C}_+$) is empty.

Proposition 9.2.4.1 is a special case of the following more general result:

06EL **Theorem 9.2.4.3.** *Let $\kappa \leq \lambda$ be regular cardinals and suppose we are given a categorical pullback diagram of ∞ -categories*

06EM

$$\begin{array}{ccc} \mathcal{C}_{\pm} & \xrightarrow{E_+} & \mathcal{C}_+ \\ \downarrow E_- & & \downarrow F_+ \\ \mathcal{C}_- & \xrightarrow{F_-} & \mathcal{C} \end{array} \quad (9.4)$$

satisfying the following conditions:

- (1) *The ∞ -categories $\mathcal{C}_-$, $\mathcal{C}$, and $\mathcal{C}_+$ are λ -filtered.*
- (2) *The functors F_- and F_+ are right cofinal.*

- (3) The ∞ -categories $\mathcal{C}_-$ and $\mathcal{C}_+$ are κ -sequentially cocomplete, and the functors F_- and F_+ preserve κ -sequential colimits (see Definition 9.2.3.1).

Then the ∞ -category $\mathcal{C}_\pm$ is λ -filtered, and the functor E_- and E_+ are right cofinal.

Remark 9.2.4.4. In the situation of Theorem 9.2.4.3, the ∞ -category $\mathcal{C}_\pm$ is also κ -sequentially cocomplete, and the functors E_- and E_+ preserve κ -sequential colimits. See Proposition 7.1.9.1. 06EN

Proof of Proposition 9.2.4.1. Apply Theorem 9.2.4.3 in the special case $\kappa = \lambda = \aleph_0$. $\square$

The main difficulty in proving Theorem 9.2.4.3 is to show that hypothesis (3) rules out the behavior described in Warning 9.2.4.2. We can formulate this more precisely as follows:

Lemma 9.2.4.5. Let κ be a regular cardinal, let $\mathcal{C}_-$ and $\mathcal{C}_+$ be ∞ -categories which are κ -filtered and κ -sequentially cocomplete, and let $\mathcal{C}$ be a κ -filtered ∞ -category. Let $F_- : \mathcal{C}_- \rightarrow \mathcal{C}$ and $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$ be functors which are right cofinal and preserve κ -sequential colimits. Then the homotopy fiber product $\mathcal{C}_- \times_{\mathcal{C}}^h \mathcal{C}_+$ is nonempty. 06EP

Proof. Recall that every ordinal α can be written uniquely as a sum $\alpha_0 + n$, where α_0 is a limit ordinal and n is a nonnegative integer. Let us say that α is *even* if n is an even integer, and that α is *odd* if n is an odd integer. For every ordinal $\beta \leq \kappa$, let $\text{Ord}_{<\beta}^+$ denote the linearly ordered set of even ordinals which are smaller than β , and let $\text{Ord}_{<\beta}^-$ denote the linearly ordered set of odd ordinals which are smaller than β . We will construct a commutative diagram of ∞ -categories

$$\begin{array}{ccccc}
 N_\bullet(\text{Ord}_{<\kappa}^-) & \longrightarrow & N_\bullet(\text{Ord}_{<\kappa}) & \longleftarrow & N_\bullet(\text{Ord}_{<\kappa}^+) \\
 \downarrow T^- & & \downarrow T & & \downarrow T^+ \\
 \mathcal{C}_- & \xrightarrow{F_-} & \mathcal{C} & \xleftarrow{F_+} & \mathcal{C}_+ .
 \end{array} \tag{9.5}$$
06EQ

Assuming this is possible, our assumption that $\mathcal{C}_-$ and $\mathcal{C}_+$ are κ -sequentially cocomplete guarantees that the diagrams T^- and T^+ admit colimits $C_- = \varinjlim(T^-)$ and $C_+ = \varinjlim(T^+)$ in the ∞ -categories $\mathcal{C}_-$ and $\mathcal{C}_+$, respectively. Since the functors F_- preserves κ -sequential colimits, the object $F_-(C_-) \in \mathcal{C}$ is a colimit of the diagram $F_- \circ T^- = T|_{N_\bullet(\text{Ord}_{<\kappa}^-)}$. Similarly, $F_+(C_+)$ is a colimit of the diagram $F_+ \circ T^+ = T|_{N_\bullet(\text{Ord}_{<\kappa}^+)}$. Corollary 7.2.3.4 guarantees that the inclusion maps $N_\bullet(\text{Ord}_{<\kappa}^-) \hookrightarrow N_\bullet(\text{Ord}_{<\kappa}) \hookleftarrow N_\bullet(\text{Ord}_{<\kappa}^+)$ are right cofinal, so that $F_-(C_-)$ and $F_+(C_+)$ can also be viewed as colimits of the diagram T (Corollary 7.2.2.11). Using Proposition 7.1.1.12, we can choose an isomorphism $u : F_-(C_-) \rightarrow F_+(C_+)$ in the ∞ -category $\mathcal{C}$. It follows that the triple (C_-, C_+, u) can be viewed as an object of the homotopy fiber product $\mathcal{C}_- \times_{\mathcal{C}}^h \mathcal{C}_+$.

It remains to construct the diagram (9.5). Let P denote the collection of all tuples $(\alpha, T_{<\alpha}, T_{<\alpha}^-, T_{<\alpha}^+)$ where $\alpha \leq \kappa$ is an ordinal and

$$T_{<\alpha}^- : N_\bullet(\text{Ord}_{<\alpha}^-) \rightarrow \mathcal{C}_- \quad T_{<\alpha} : N_\bullet(\text{Ord}_{<\alpha}) \rightarrow \mathcal{C} \quad T_{<\alpha}^+ : N_\bullet(\text{Ord}_{<\alpha}^+) \rightarrow \mathcal{C}_+$$

are functors satisfying $F_- \circ T_{<\alpha}^- = T_{<\alpha}|_{N_\bullet(\text{Ord}_{<\alpha}^-)}$ and $F_+ \circ T_{<\alpha}^+ = T_{<\alpha}|_{N_\bullet(\text{Ord}_{<\alpha}^+)}$. We regard P as a partially ordered set, where $(\alpha, T_{<\alpha}, T_{<\alpha}^-, T_{<\alpha}^+) \leq (\beta, T_{<\beta}, T_{<\beta}^-, T_{<\beta}^+)$ if $\alpha \leq \beta$ and the functors $T_{<\alpha}$, $T_{<\alpha}^-$, and $T_{<\alpha}^+$ are the restrictions of $T_{<\beta}$, $T_{<\beta}^-$, and $T_{<\beta}^+$, respectively. The partially ordered set P satisfies the hypotheses of Zorn's lemma, and therefore contains a maximal element $(\gamma, T_{<\gamma}, T_{<\gamma}^-, T_{<\gamma}^+)$. To complete the proof, it will suffice to show that $\gamma = \kappa$. Assume otherwise. For simplicity, we will assume that γ is even (the case where γ is odd can be handled by a similar argument). To obtain a contradiction, it will suffice to show that $T_{<\gamma}$ and $T_{<\gamma}^+$ can be extended to functors

$$T_{\leq\gamma} : N_\bullet(\text{Ord}_{\leq\gamma}) \rightarrow \mathcal{C} \quad T_{\leq\gamma}^+ : N_\bullet(\text{Ord}_{\leq\gamma}^+) \rightarrow \mathcal{C}_+$$

satisfying $F_+ \circ T_{\leq\gamma}^+ = T_{\leq\gamma}|_{N_\bullet(\text{Ord}_{\leq\gamma}^+)}$. Unwinding the definitions, we must show that the ∞ -category

$$\mathcal{E} = \mathcal{C}_{T_{<\gamma}/} \times_{\mathcal{C}_{(F_+ \circ T_{<\gamma}^+)/}} (\mathcal{C}_+)_{T_{<\gamma}^+/}$$

is nonempty. We distinguish two cases:

- Suppose that γ is a limit ordinal. Then the inclusion map $N_\bullet(\text{Ord}_{<\gamma}^+) \hookrightarrow N_\bullet(\text{Ord}_{<\gamma})$ is right cofinal (Corollary 7.2.3.4) and therefore right anodyne (Proposition 7.2.1.3). Applying Proposition 4.3.6.13, we deduce that the restriction map $\mathcal{C}_{T_{<\gamma}/} \rightarrow \mathcal{C}_{(F_+ \circ T_{<\gamma}^+)/}$ is a trivial Kan fibration. It follows that projection onto the second factor induces a trivial Kan fibration $\mathcal{E} \rightarrow (\mathcal{C}_+)_{T_{<\gamma}^+/}$. In particular, to show that $\mathcal{E}$ is nonempty, it suffices to show that the coslice ∞ -category $(\mathcal{C}_+)_{T_{<\gamma}^+/}$ is nonempty. This follows from our assumption that $\mathcal{C}_+$ is κ -filtered, since the simplicial set $N_\bullet(\text{Ord}_{<\gamma}^+)$ is κ -small.
- Suppose that $\gamma = \beta + 1$ is the successor of an odd ordinal β . Set $A = \text{Ord}_{<\gamma}^+ \cup \{\beta\}$. Then the inclusion map $N_\bullet(A) \hookrightarrow N_\bullet(\text{Ord}_{<\gamma})$ is right cofinal (Corollary 7.2.3.4) and therefore right anodyne (Proposition 7.2.1.3). Let $T' = T_{<\gamma}|_{N_\bullet(A)}$. Then the restriction map $\mathcal{C}_{T_{<\gamma}/} \rightarrow \mathcal{C}_{T' /}$ is a trivial Kan fibration (Proposition 4.3.6.13), and therefore induces a trivial Kan fibration from $\mathcal{E}$ to the ∞ -category

$$\mathcal{E}' = \mathcal{C}_{T' /} \times_{\mathcal{C}_{(F_+ \circ T_{<\gamma}^+)/}} (\mathcal{C}_+)_{T_{<\gamma}^+/}.$$

We will complete the proof by showing that $\mathcal{E}'$ is weakly contractible (and therefore nonempty). This follows from Theorem 7.2.3.1, since F_+ is a right cofinal functor of κ -filtered ∞ -categories and therefore induces a cofinal functor of coslice ∞ -categories $(\mathcal{C}_+)_{T_{<\gamma}^+/} \rightarrow \mathcal{C}_{(F_+ \circ T_{<\gamma}^+)/}$ (Corollary 9.1.4.18), because the simplicial set $N_\bullet(\text{Ord}_{<\gamma}^+)$ is κ -small.

□

Proof of Theorem 9.2.4.3. Let $\kappa \leq \lambda$ be regular cardinals and let

$$\begin{array}{ccc}
 \mathcal{C}_{\pm} & \xrightarrow{E_+} & \mathcal{C}_+ \\
 \downarrow E_- & & \downarrow F_+ \\
 \mathcal{C}_- & \xrightarrow{F_-} & \mathcal{C}
 \end{array} \tag{9.6}$$

be a categorical pullback diagram of ∞ -categories which satisfies conditions (1), (2), and (3) of Theorem 9.2.4.3, and let $E : \mathcal{C}_{\pm} \rightarrow \mathcal{C}$ be the functor given by the composition $F_+ \circ E_+ = F_- \circ E_-$. For every λ -small diagram $q : K \rightarrow \mathcal{C}_{\pm}$, the induced diagram of coslice ∞ -categories

$$\begin{array}{ccc}
 (\mathcal{C}_{\pm})_{q/} & \longrightarrow & (\mathcal{C}_+)_{(E_+ \circ q)/} \\
 \downarrow & & \downarrow \\
 (\mathcal{C}_-)_{(E_- \circ q)/} & \longrightarrow & \mathcal{C}_{(E \circ q)/}
 \end{array}$$

is also a categorical pullback square (Corollary 4.6.4.22) satisfying conditions (1), (2), and (3) of Theorem 9.2.4.3: condition (1) follows from Proposition 9.1.1.16, condition (2) from Corollary 9.1.4.18, and condition (3) from Corollary 7.1.7.5. Applying Lemma 9.2.4.5, we deduce that the ∞ -category $(\mathcal{C}_{\pm})_{q/}$ is nonempty. Allowing q to vary, we conclude that the ∞ -category $\mathcal{C}_{\pm}$ is λ -filtered.

We will complete the proof by showing that the functor E_- is right cofinal (the assertion that E_+ is right cofinal follows by a similar argument). By virtue of Theorem 9.1.4.5, it will suffice to show that for every object $X \in \mathcal{C}_{\pm}$, the induced map of coslice ∞ -categories $(\mathcal{C}_{\pm})_{X/} \rightarrow (\mathcal{C}_-)_{E_-(X)/}$ is weakly right cofinal. Arguing as above, we can replace (9.6) by the diagram of coslice ∞ -categories

$$\begin{array}{ccc}
 (\mathcal{C}_{\pm})_{X/} & \longrightarrow & (\mathcal{C}_+)_{E_+(X)/} \\
 \downarrow & & \downarrow \\
 (\mathcal{C}_-)_{E_-(X)/} & \longrightarrow & \mathcal{C}_{E(X)/}
 \end{array}$$

and thereby reduce to the problem of showing that the functor E_- is weakly cofinal. Fix an object $Y \in \mathcal{C}_-$; we wish to show that the ∞ -category $\mathcal{C}_{\pm} \times_{\mathcal{C}_-} (\mathcal{C}_-)_{Y/}$ is nonempty.

This follows by applying Lemma 9.2.4.5 to the outer rectangle in the commutative diagram

$$\begin{array}{ccccc}
 \mathcal{C}_{\pm} \times_{\mathcal{C}_{-}} (\mathcal{C}_{-})_{Y/} & \longrightarrow & \mathcal{C}_{\pm} & \xrightarrow{E_{+}} & \mathcal{C}_{+} \\
 \downarrow & & \downarrow E_{-} & & \downarrow F_{+} \\
 (\mathcal{C}_{-})_{Y/} & \longrightarrow & \mathcal{C}_{-} & \xrightarrow{F_{-}} & \mathcal{C};
 \end{array}$$

note that the bottom horizontal composition is right cofinal by virtue of Corollary 9.1.4.16. $\square$

9.2.5 Compact Objects

0649 We now formulate an ∞ -categorical counterpart of Definition 9.2.0.2.

064A **Definition 9.2.5.1.** Let $\mathcal{C}$ be an ∞ -category which admits small filtered colimits. We say that an object $C \in \mathcal{C}$ is *compact* if the corepresentable functor $\mathrm{Hom}_{\mathcal{C}}(C, \bullet) : \mathcal{C} \rightarrow \mathcal{S}$ is finitary: that is, it preserves small filtered colimits.

064B **Warning 9.2.5.2.** In the formulation of Definition 9.2.5.1, we have implicitly assumed that the ∞ -category $\mathcal{C}$ is locally small (so that the corepresentable functor $\mathrm{Hom}_{\mathcal{C}}(C, \bullet) : \mathcal{C} \rightarrow \mathcal{S}$ is well-defined). More generally, let μ be a regular cardinal which is not small such that $\mathcal{C}$ is locally μ -small. In this case, we say that $C \in \mathcal{C}$ is *compact* if the corepresentable functor $\mathrm{Hom}_{\mathcal{C}}(C, \bullet) : \mathcal{C} \rightarrow \mathcal{S}_{<\mu}$ is finitary. It follows from Corollary 7.4.3.8 that this condition does not depend on the choice of μ .

064C **Example 9.2.5.3.** Let $\mathcal{C}$ be a category which admits small filtered colimits. Then the nerve $N_{\bullet}(\mathcal{C})$ is an ∞ -category which admits small filtered colimits (Corollary 9.2.1.13). Moreover, an object $C \in \mathcal{C}$ is compact (in the sense of Definition 9.2.0.2) if and only if it is compact when viewed as an object of the ∞ -category $N_{\bullet}(\mathcal{C})$ (in the sense of Definition 9.2.5.1). This follows from Proposition 9.2.2.25, since the inclusion functor $N_{\bullet}(\mathrm{Set}) \hookrightarrow \mathcal{S}$ is finitary (see Variant 9.1.6.4).

064D **Example 9.2.5.4.** The Kan complex Δ^0 corepresents the identity functor $\mathrm{id} : \mathcal{S} \rightarrow \mathcal{S}$ (see Proposition 5.6.6.17), and is therefore compact when viewed as an object of the ∞ -category of spaces $\mathcal{S}$ (Example 9.2.2.9). See Corollary 9.2.6.5 for a more general statement.

064E **Example 9.2.5.5.** Let X be a Kan complex, which we view as an ∞ -category in which every morphism is an isomorphism. Then X admits small filtered colimits which are preserved by any functor of ∞ -categories $X \rightarrow \mathcal{C}$ (see Example 7.3.9.5). It follows that every vertex $x \in X$ is a compact object of X .

It will often be useful to consider an infinitary generalization of Definition 9.2.5.1.

Definition 9.2.5.6. Let κ be a small regular cardinal, and let $\mathcal{C}$ be an ∞ -category which admits small κ -filtered colimits. We say that an object $C \in \mathcal{C}$ is κ -compact if the corepresentable functor $\mathrm{Hom}_{\mathcal{C}}(C, \bullet)$ is κ -finitary: that is, it preserves small κ -filtered colimits. We will sometimes write $\mathcal{C}_{<\kappa}$ for the full subcategory of $\mathcal{C}$ spanned by the κ -compact objects. 064F

Warning 9.2.5.7. Let κ be an uncountable regular cardinal. We have now assigned two meanings to the notation $\mathcal{C}_{<\kappa}$ in the cases $\mathcal{C} = \mathcal{S}$ and $\mathcal{C} = \mathcal{QC}$: 064G

- Following the convention of Remark 5.5.4.12 and Variant 5.5.4.13, $\mathcal{C}_{<\kappa}$ denotes the full subcategory of $\mathcal{C}$ spanned by those objects which are κ -small when viewed as simplicial sets.
- Following the convention of Definition 9.2.5.6, $\mathcal{C}_{<\kappa}$ denotes the full subcategory of $\mathcal{C}$ spanned by those objects which are κ -compact.

However, these conventions are almost compatible: we will see later that a Kan complex is κ -compact (as an object of $\mathcal{S}$) if and only if it is essentially κ -small (Proposition 9.2.6.9). Similarly, a small ∞ -category is κ -compact (as an object of $\mathcal{QC}$) if and only if it is essentially κ -small (Proposition 9.2.7.14).

Example 9.2.5.8. Let $\mathcal{C}$ be an ∞ -category which admits small filtered colimits. Then an object $C \in \mathcal{C}$ is compact (in the sense of Definition 9.2.5.1) if and only if it is $\aleph_0$ -compact (in the sense of Definition 9.2.5.6). 064H

Example 9.2.5.9. Let κ be a (small) regular cardinal. For every (small) set S , the following conditions are equivalent: 064J

- (1) The set S is κ -small: that is, it has cardinality $< \kappa$.
- (2) The set S is κ -compact when viewed as an object of (the nerve of) the category of sets.

To prove the implication (1) $\Rightarrow$ (2), we can use the decomposition $S \simeq \coprod_{s \in S} \{s\}$ to reduce to the case where S consists of a single element (Corollary 9.2.5.24). In this case, S corepresents the identity functor $\mathrm{id} : \mathrm{Set} \rightarrow \mathrm{Set}$, which preserves all colimits. For the converse, we observe that S can be realized as a κ -filtered colimit of κ -small subsets of itself. Consequently, if S is κ -compact, then the identity function $\mathrm{id} : S \rightarrow S$ factors through some κ -small subset $S_0 \subseteq S$. It follows that $S = S_0$ is κ -small.

Variant 9.2.5.10. Let κ be a (small) regular cardinal and let X be a (small) simplicial set. Then X is κ -compact (as an object of the ordinary category of simplicial sets) if and only if it is κ -small (in the sense of Definition 4.7.4.1). 064K

Proof. If $\kappa = \aleph_0$, this is a restatement of Variant 9.2.0.5. We may therefore assume without loss of generality that κ is uncountable. Assume first that X is a κ -small simplicial set, and let Δ_X be the category of simplices of X (Construction 1.1.3.9). Then X can be realized as a colimit $\varinjlim_{([n], \sigma) \in \Delta_X} \Delta^n$ (see the proof of Proposition 1.1.3.11, or Theorem 8.4.2.1). Each of the standard simplices Δ^n is a κ -compact object of the category Set_Δ , since the evaluation functor $(Y_\bullet \in \text{Set}_\Delta) \mapsto Y_n$ preserves colimits (Remark 1.1.0.8). Our assumption that X is κ -small guarantees that the category Δ_X is κ -small (Proposition 4.7.4.10), so that X is κ -compact by virtue of Proposition 9.2.5.23.

We now prove the converse. As in Example 9.2.5.9, we can realize X as a κ -filtered colimit $\varinjlim_{\alpha \in A} X_\alpha$, where $\{X_\alpha\}_{\alpha \in A}$ is the collection of all κ -small simplicial subsets of X . If X is κ -compact, then the identity map id_X factors through some X_α , so that $X = X_\alpha$ is κ -small. $\square$

064L **Variant 9.2.5.11.** Let κ be a regular cardinal, let Y be a set, and let $\text{Sub}(Y)$ be the collection of all subsets of Y , viewed as a partially ordered set (with respect to inclusion). A subset $X \subseteq Y$ is κ -small if and only if it is κ -compact when viewed as an object of the ∞ -category $\mathbf{N}_\bullet(\text{Sub}(Y))$.

064M **Definition 9.2.5.12.** Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete. We say that an object $C \in \mathcal{C}$ is (κ, λ) -compact if the corepresentable functor

$$\text{Hom}_{\mathcal{C}}(C, \bullet) : \mathcal{C} \rightarrow \mathcal{S}_{<\mu} \quad D \mapsto \text{Hom}_{\mathcal{C}}(C, D)$$

is (κ, λ) -finitary: that is, it preserves λ -small κ -filtered colimits. Here μ is any cardinal of cofinality $\geq \lambda$ such that $\mathcal{C}$ is locally μ -small (it follows from Corollary 7.4.3.8 that this condition does not depend on the choice of μ).

064N **Remark 9.2.5.13.** In the situation of Definition 9.2.5.12, the corepresentable functor $\text{Hom}_{\mathcal{C}}(C, \bullet)$ is only well-defined up to isomorphism. However, the condition that the functor $\text{Hom}_{\mathcal{C}}(C, \bullet)$ is (κ, λ) -finitary depends only on its isomorphism class.

064P **Remark 9.2.5.14.** Following the convention of Remark 4.7.0.5, a regular cardinal κ is small if it satisfies $\kappa < \Omega$, for some fixed strongly inaccessible cardinal Ω . If $\mathcal{C}$ is an ∞ -category which admits small κ -filtered colimits, then an object $C \in \mathcal{C}$ is κ -compact (in the sense of Definition 9.2.5.6) if and only if it is (κ, Ω) -compact (in the sense of Definition 9.2.5.12). In particular, if $\mathcal{C}$ admits small filtered colimits, then an object $C \in \mathcal{C}$ is compact if and only if it is $(\aleph_0, \Omega)$ -compact.

064Q **Example 9.2.5.15.** Let $\mathcal{C}$ be an ∞ -category and let κ be a regular cardinal. Assume either that $\kappa = \aleph_0$ or that $\mathcal{C}$ is idempotent-complete, so that $\mathcal{C}$ is (κ, κ) -cocomplete (Proposition 9.2.1.14). Then every object $C \in \mathcal{C}$ is (κ, κ) -compact. See Example 9.2.2.16.

Example 9.2.5.16. Let $\mathcal{C}$ be an ∞ -category which is sequentially cocomplete. Then an object $C \in \mathcal{C}$ is $(\aleph_0, \aleph_1)$ -compact if and only if the corepresentable functor $\mathrm{Hom}_{\mathcal{C}}(C, \bullet)$ commutes with sequential colimits. See Corollary 9.2.3.8. 064R

Remark 9.2.5.17 (Monotonicity). Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete, and let C be an object which is (κ, λ) -compact. Then C is also (κ', λ') -compact for all regular cardinals κ' and λ' satisfying $\kappa \leq \kappa' \leq \lambda' \leq \lambda$. See Remark 9.2.2.8. 064S

Remark 9.2.5.18 (Retracts). Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete, and let $C \in \mathcal{C}$ be an object. If C is (κ, λ) -compact, then any retract of C is also (κ, λ) -compact. See Remark 9.2.2.13. 064Z

Remark 9.2.5.19. Let $\kappa \leq \lambda$ be regular cardinals and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, where $\mathcal{C}$ and $\mathcal{D}$ are (κ, λ) -cocomplete, and let C be a (κ, λ) -compact object of $\mathcal{C}$. If F admits a (κ, λ) -finitary right adjoint $G : \mathcal{D} \rightarrow \mathcal{C}$, then $F(C)$ is a (κ, λ) -compact object of $\mathcal{D}$. This follows from the observation that $F(C)$ corepresents the composite functor $\mathcal{D} \xrightarrow{G} \mathcal{C} \xrightarrow{\mathrm{Hom}_{\mathcal{C}}(C, \bullet)} \mathcal{S}_{<\mu}$, where μ is any regular cardinal for which $\mathcal{C}$ is locally μ -small. See Remark 6.2.6.3. 06ES

Definition 9.2.5.12 makes sense for every pair of regular cardinals $\kappa \leq \lambda$. However, it is primarily of interest in the case $\kappa \leq \lambda$, in the sense of Definition 9.1.7.5 (see Warning 9.2.2.7).

Proposition 9.2.5.20. Let κ , λ , and μ be regular cardinals satisfying $\kappa \leq \lambda \leq \mu$, and let $\mathcal{C}$ be an ∞ -category which is (κ, μ) -cocomplete. Then an object $C \in \mathcal{C}$ is (κ, μ) -compact if and only if it is both (κ, λ) -compact and (λ, μ) -compact. 064T

Proof. Apply Proposition 9.2.2.29 to the corepresentable functor $\mathrm{Hom}_{\mathcal{C}}(C, \bullet)$. $\square$

Corollary 9.2.5.21. Let κ and λ be small regular cardinals satisfying $\kappa \leq \lambda$, and let $\mathcal{C}$ be an ∞ -category which admits small κ -filtered colimits. Then an object $C \in \mathcal{C}$ is κ -compact if and only if it is both (κ, λ) -compact and λ -compact. 064U

Corollary 9.2.5.22. Let λ be a small regular cardinal and let $\mathcal{C}$ be an ∞ -category which admits small filtered colimits. Then an object $C \in \mathcal{C}$ is compact if and only if it is both $(\aleph_0, \lambda)$ -compact and λ -compact. 064V

Proposition 9.2.5.23. Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete. Then the collection of (κ, λ) -compact objects of $\mathcal{C}$ is closed under κ -small colimits. 064W

Proof. Fix an uncountable cardinal μ having cofinality $\geq \lambda$ and exponential cofinality $\geq \kappa$, and such that $\mathcal{C}$ is locally μ -small. Let $\text{Fun}^{(\kappa, \lambda)\text{-fin}}(\mathcal{C}, \mathcal{S}_{<\mu})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{S}_{<\mu})$ spanned by the (κ, λ) -finitary functors. Then the subcategory $\text{Fun}^{(\kappa, \lambda)\text{-fin}}(\mathcal{C}, \mathcal{S}_{<\mu})$ is closed under κ -small limits (Remark 9.2.2.17). By definition, an object $C \in \mathcal{C}$ is (κ, λ) -compact if and only if the contravariant Yoneda embedding $h^\bullet : \mathcal{C}^{\text{op}} \rightarrow \text{Fun}(\mathcal{C}, \mathcal{S}_{<\mu})$ carries C to an object of $\text{Fun}^{(\kappa, \lambda)\text{-fin}}(\mathcal{C}, \mathcal{S}_{<\mu})$. The desired result now follows from the observation that $h^\bullet$ is κ -continuous (see Proposition 7.4.1.18). $\square$

064X **Corollary 9.2.5.24.** *Let κ be a small regular cardinal and let $\mathcal{C}$ be an ∞ -category which admits small κ -filtered colimits. Then the collection of κ -compact objects of $\mathcal{C}$ is closed under κ -small colimits.*

064Y **Corollary 9.2.5.25.** *Let $\mathcal{C}$ be an ∞ -category which admits small filtered colimits. Then the collection of compact objects of $\mathcal{C}$ is closed under finite colimits.*

9.2.6 Finiteness Conditions on Kan Complexes

067N We now study compact objects of the ∞ -category of spaces $\mathcal{S}$ (see Construction 5.5.1.1).

067P **Definition 9.2.6.1.** Let X be a Kan complex. We say that X is *essentially finite* if there exists a weak homotopy equivalence $K \rightarrow X$, where K is a finite simplicial set.

067Q **Remark 9.2.6.2.** A Kan complex X is essentially finite if and only if it is homotopy equivalent to the Kan complex $\text{Ex}^\infty(K)$, for some finite simplicial set K . See Proposition 3.3.6.7.

067R **Proposition 9.2.6.3.** *Let $\mathcal{S}_{\text{fin}}$ denote the smallest full subcategory of $\mathcal{S}$ which contains Δ^0 and is closed under finite colimits. Then a Kan complex X belongs to $\mathcal{S}_{\text{fin}}$ if and only if it is essentially finite.*

Proof. Assume first that X is essentially finite: that is, there exists a weak homotopy equivalence $K \rightarrow X$, where K is a finite simplicial set. Then X can be realized as the colimit of the constant diagram $K \rightarrow \{\Delta^0\} \hookrightarrow \mathcal{S}$ (Example 7.1.2.9), and therefore belongs to $\mathcal{S}_{\text{fin}}$.

To prove the converse, we will show that the collection of essentially finite Kan complexes is closed under finite colimits (in the ∞ -category $\mathcal{S}$). Since the initial object $\emptyset \in \mathcal{S}$ is finite (and therefore essentially finite), it will suffice to show that the collection of essentially finite Kan complexes is closed under pushouts (Corollary 7.6.2.30). By virtue of Example 7.6.3.3 (and Corollary 5.6.5.18), this is equivalent to the following more concrete assertion:

(*) Suppose we are given a homotopy pushout diagram of Kan complexes

$$\begin{array}{ccc} X & \xrightarrow{f_0} & X_0 \\ \downarrow f_1 & & \downarrow \\ X_1 & \longrightarrow & X_{01}. \end{array} \quad \begin{array}{l} 067S \\ (9.7) \end{array}$$

If X , X_0 , and X_1 are essentially finite, then X_{01} is also essentially finite.

To prove (*), we may assume without loss of generality that $X_0 = \mathrm{Ex}^\infty(K_0)$ and $X_1 = \mathrm{Ex}^\infty(K_1)$, for some finite simplicial sets K_0 and K_1 (Remark 9.2.6.2). Choose a weak homotopy equivalence $u : K \rightarrow X$, where K is a finite simplicial set. Since K is finite, the morphisms $f_0 \circ u$ and $f_1 \circ u$ factor through $\mathrm{Ex}^n(K_0)$ and $\mathrm{Ex}^n(K_1)$ for some integer $n \gg 0$. Using Proposition 3.3.6.7, we see that the diagram (9.7) induces a weak homotopy equivalence from the homotopy pushout $\mathrm{Ex}^n(K_0) \amalg_K^h \mathrm{Ex}^n(K_1)$ to the Kan complex X_{01} . Combining Propositions 3.3.4.8 and 3.4.2.5 with Theorem 3.3.5.1, we obtain weak homotopy equivalences

$$\begin{array}{c} \mathrm{Ex}^n(K_0) \amalg_K^h \mathrm{Ex}^n(K_1) \\ \uparrow \\ \mathrm{Sd}^n(\mathrm{Ex}^n(K_0)) \amalg_{\mathrm{Sd}^n(K)}^h \mathrm{Sd}^n(\mathrm{Ex}^n(K_1)) \\ \downarrow \\ K_0 \amalg_{\mathrm{Sd}^n(K)}^h K_1. \end{array}$$

It follows that X_{01} is weakly homotopy equivalent to the finite simplicial set $K_0 \amalg_{\mathrm{Sd}^n(K)}^h K_1$, and is therefore essentially finite. $\square$

Corollary 9.2.6.4. *Let X be a Kan complex. Then X is essentially finite if and only if it is homotopy equivalent to a simplicial set of the form $\mathrm{Sing}_\bullet(Y)$, where Y is a finite CW complex.* 067T

Proof. Assume first that X is essentially finite: that is, there exists a weak homotopy equivalence $f : K \rightarrow X$, where K is a finite simplicial set. Then f induces a homotopy equivalence of topological spaces $|K| \rightarrow |X|$ (Corollary 3.6.4.3), and therefore a homotopy equivalence of Kan complexes $\mathrm{Sing}_\bullet(|K|) \rightarrow \mathrm{Sing}_\bullet(|X|)$ (Example 3.1.6.3). The unit map

$X \rightarrow \text{Sing}_\bullet(|X|)$ is a weak homotopy equivalence between Kan complexes (Theorem 3.6.4.1), and therefore a homotopy equivalence (Proposition 3.1.6.13). It follows that X is homotopy equivalent to $\text{Sing}_\bullet(Y)$, where $Y = |K|$ is a finite CW complex (Remark 1.2.3.12).

To prove the converse, it will suffice to show that if Y is a finite CW complex, then the singular simplicial set $\text{Sing}_\bullet(Y)$ is essentially finite. We proceed by induction on the number of cells of Y (with respect to any choice of CW decomposition). If Y is empty, there is nothing to prove. Otherwise, fix a cell $U \subseteq Y$ of maximal dimension d , so that $Y_0 = Y \setminus U$ is a finite CW complex with a smaller number of cells. Choose a point $y \in U$. Applying Theorem 3.4.6.1, we deduce that the diagram of Kan complexes

$$\begin{array}{ccc} \text{Sing}_\bullet(U \setminus \{y\}) & \longrightarrow & \text{Sing}_\bullet(U) \\ \downarrow & & \downarrow \\ \text{Sing}_\bullet(Y \setminus \{y\}) & \longrightarrow & \text{Sing}_\bullet(Y) \end{array}$$

is a homotopy pushout square of simplicial sets, and therefore a pushout square in the ∞ -category $\mathcal{S}$ (Example 7.6.3.3). Note that U is contractible and $U \setminus \{y\}$ is homotopy equivalent to a sphere S^{n-1} , so that $\text{Sing}_\bullet(U)$ and $\text{Sing}_\bullet(U \setminus \{y\})$ are weakly homotopy equivalent to Δ^0 and $\partial\Delta^n$, respectively. The topological space $Y \setminus \{y\}$ is homotopy equivalent to Y_0 , so that $\text{Sing}_\bullet(Y \setminus \{y\})$ is essentially finite by virtue of our inductive hypothesis. Applying Proposition 9.2.6.3, we conclude that $\text{Sing}_\bullet(Y)$ is also essentially finite. $\square$

067U **Corollary 9.2.6.5.** *Let X be an essentially finite Kan complex. Then X is compact when viewed as an object of the ∞ -category $\mathcal{S}$.*

Proof. Since the collection of compact objects of $\mathcal{S}$ is closed under finite colimits (Corollary 9.2.5.25), this follows from the observation that $\Delta^0 \in \mathcal{S}$ is compact (Example 9.2.5.4). $\square$

067W **Definition 9.2.6.6.** Let X be a Kan complex. We say that X is *finitely dominated* if it is a retract (in the homotopy category hKan) of an essentially finite Kan complex.

067X **Proposition 9.2.6.7.** *Let X be a Kan complex. Then X is finitely dominated if and only if it is compact when viewed as an object of the ∞ -category $\mathcal{S}$.*

Proof. If X is finitely dominated, then it is a retract of an essentially finite Kan complex Y . Since Y is a compact object of $\mathcal{S}$ (Corollary 9.2.6.5), it follows that X is also a compact object of $\mathcal{S}$ (Remark 9.2.5.18).

Conversely, suppose that X is a compact object of $\mathcal{S}$. Let $\{X_\alpha\}_{\alpha \in A}$ be the collection of all finite simplicial subsets of X , and let $\text{Ex}^\infty : \text{Set}_\Delta \rightarrow \text{Set}_\Delta$ be the functor defined in Construction 3.3.6.1. Then $\text{Ex}^\infty(X)$ can be identified with the filtered colimit $\varinjlim_{\alpha \in A} \text{Ex}^\infty(X_\alpha)$

in the ordinary category of simplicial sets, and therefore also in the ∞ -category $\mathcal{S}$ (Variant 9.1.6.4). Since X is compact, the functor

$$\mathcal{S} \rightarrow \mathbf{N}_\bullet(\mathbf{Set}) \quad Y \mapsto \pi_0(\mathrm{Hom}_{\mathcal{S}}(X, Y)) = \mathrm{Hom}_{\mathbf{hKan}}(X, Y)$$

preserves filtered colimits, and therefore induces a bijection

$$\varinjlim_{\alpha \in A} \mathrm{Hom}_{\mathbf{hKan}}(X, \mathrm{Ex}^\infty(X_\alpha)) \rightarrow \mathrm{Hom}_{\mathbf{hKan}}(X, \mathrm{Ex}^\infty(X)).$$

In particular, the homotopy equivalence $X \rightarrow \mathrm{Ex}^\infty(X)$ of Proposition 3.3.6.7 factors through $\mathrm{Ex}^\infty(X_\alpha)$ for some $\alpha \in A$. It follows that X is a retract of the essentially finite Kan complex $\mathrm{Ex}^\infty(X_\alpha)$, and is therefore finitely dominated. $\square$

Warning 9.2.6.8. Let X be a Kan complex. If X is essentially finite, then it is finitely dominated. The converse holds if X is simply connected, but not in general (see [65]). We will return to this point in §[?]. 067Y

We now study weaker finiteness conditions.

Proposition 9.2.6.9. *Let κ be an uncountable regular cardinal and let X be a Kan complex. The following conditions are equivalent:* 0680

- (1) *The Kan complex X is essentially κ -small (Definition 4.7.5.1).*
- (2) *The Kan complex X belongs to the smallest full subcategory of $\mathcal{S}$ which contains Δ^0 and is closed under κ -small colimits.*
- (3) *The Kan complex X is κ -compact when viewed as an object of the ∞ -category $\mathcal{S}$.*

In the formulation of Proposition 9.2.6.9, we have implicitly assumed that the cardinal κ and the Kan complex X are small. Following the convention of Remark 4.7.0.5, we can regard Proposition 9.2.6.9 as a special case of the following more precise assertion:

Proposition 9.2.6.10. *Let κ and λ be uncountable regular cardinals satisfying $\kappa \trianglelefteq \lambda$ and let X be a λ -small Kan complex. The following conditions are equivalent:* 0681

- (1) *The Kan complex X is essentially κ -small.*
- (2) *The Kan complex X belongs to the smallest full subcategory of $\mathcal{S}_{<\lambda}$ which contains Δ^0 and is closed under κ -small colimits.*
- (3) *The Kan complex X is (κ, λ) -compact when viewed as an object of the ∞ -category $\mathcal{S}_{<\lambda}$.*

Proof. If X is essentially κ -small, then there exists a weak homotopy equivalence $K \rightarrow X$, where K is a κ -small simplicial set. In this case, X can be viewed as a colimit of the constant diagram $K \rightarrow \{\Delta^0\} \hookrightarrow \mathcal{S}_{<\lambda}$ (Example 7.1.2.9). This proves the implication (1) $\Rightarrow$ (2). Note that the object $\Delta^0 \in \mathcal{S}_{<\lambda}$ corepresents the identity functor $\text{id} : \mathcal{S}_{<\lambda} \rightarrow \mathcal{S}_{<\lambda}$, and is therefore (κ, λ) -compact. Consequently, the implication (2) $\Rightarrow$ (3) follows from Proposition 9.2.5.23.

We will complete the proof by showing that (3) implies (1). Suppose that X is (κ, λ) -compact when viewed as an object of the ∞ -category $\mathcal{S}_{<\lambda}$; we wish to show that X is essentially κ -small. We proceed as in the proof of Proposition 9.2.6.7. Without loss of generality we may assume that X is λ -small. Using our assumption that $\kappa \leq \lambda$, we can choose a λ -small collection of κ -small simplicial subsets $\{X_\alpha\}_{\alpha \in A}$ such that every κ -small simplicial subset of X is contained in some X_α (Lemma 9.1.7.18). We regard A as a partially ordered set, with $\alpha \leq \beta$ if X_α is contained in X_β . The partially ordered set $(A, \leq)$ is then κ -directed (Remark 9.1.7.19). Since Ex^∞ preserves filtered colimits (Proposition 3.3.6.4), we can identify $\text{Ex}^\infty(X)$ with the colimit of the diagram $\{\text{Ex}^\infty(X_\alpha)\}_{\alpha \in A}$ in the category of Kan complexes, and therefore also in the ∞ -category $\mathcal{S}_{<\lambda}$ (Variant 9.1.6.4). Arguing as in the proof of Proposition 9.2.6.7, we see that the homotopy equivalence $X \rightarrow \text{Ex}^\infty(X)$ factors up to homotopy through some $\text{Ex}^\infty(X_\alpha)$, so that X is a retract of $\text{Ex}^\infty(X_\alpha)$ in the ∞ -category $\mathcal{S}_{<\lambda}$. In particular, X can be realized as the colimit of a diagram

$$\text{Ex}^\infty(X_\alpha) \xrightarrow{e} \text{Ex}^\infty(X_\alpha) \xrightarrow{e} \text{Ex}^\infty(X_\alpha) \xrightarrow{e} \text{Ex}^\infty(X_\alpha) \rightarrow \cdots$$

in the ∞ -category $\mathcal{S}_{<\lambda}$, for some (homotopy idempotent) endomorphism e of the Kan complex $\text{Ex}^\infty(X_\alpha)$. Forming the colimit of this diagram in the ordinary category of simplicial sets, we obtain a κ -small Kan complex which is homotopy equivalent to X (Variant 7.6.5.9). $\square$

Proof of Proposition 9.2.6.9. Apply Proposition 9.2.6.10 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal (see Example 9.1.7.11). $\square$

9.2.7 Finiteness Conditions on ∞ -Categories

0685 The results of §9.2.6 have counterparts for the ∞ -category $\mathcal{QC}$ of small ∞ -categories.

0686 **Definition 9.2.7.1.** Let $\mathcal{C}$ be an ∞ -category. We say that $\mathcal{C}$ is *essentially finite* if there exists a categorical equivalence $K \rightarrow \mathcal{C}$, where K is a finite simplicial set.

Let X be a Kan complex. We have now given two definitions of what it means for X to be essentially finite:

- According to Definition 9.2.6.1, X is essentially finite if there exists a finite simplicial set K and a weak homotopy equivalence $K \rightarrow X$.
- According to Definition 9.2.7.1, X is essentially finite if there exists a finite simplicial set K and a categorical equivalence $K \rightarrow X$.

However, there is actually no conflict: we will see in a moment that these conditions are equivalent (Proposition 9.2.7.4). The proof will require the following technical result:

Lemma 9.2.7.2. *Let $\mathcal{C}$ be an ∞ -category which is essentially finite. Suppose we are given a diagram $f_0 : K_0 \rightarrow \mathcal{C}$, where K_0 is a finite simplicial set. Then f_0 factors as a composition $K_0 \xrightarrow{u} K \xrightarrow{f} \mathcal{C}$, where u is a monomorphism, K is a finite simplicial set, and f is a categorical equivalence of simplicial sets.* 0687

Proof. Since $\mathcal{C}$ is essentially finite, we can choose a categorical equivalence $U_0 : \mathcal{D}_0 \rightarrow \mathcal{C}$, where $\mathcal{D}_0$ is a finite simplicial set. Arguing as in the proof of Proposition 4.1.3.2, we can factor U_0 as a composition $\mathcal{D}_0 \xrightarrow{j} \mathcal{D} \xrightarrow{U} \mathcal{C}$, where U is an inner fibration and j is a transfinite composition of pushouts of inner horn inclusions. More precisely, we may assume that $\mathcal{D} = \mathcal{D}_\beta$ for some ordinal β and some well-ordered diagram

$$\text{Ord}_{\leq \beta} \rightarrow \text{Set}_\Delta \quad \alpha \mapsto \mathcal{D}_\alpha$$

having the following properties:

- For every ordinal $\alpha < \beta$, there is a pair of integers $0 < i < n$ and a pushout diagram of simplicial sets

$$\begin{array}{ccc} \Lambda_i^n & \xrightarrow{\quad} & \mathcal{D}_\alpha \\ \downarrow & & \downarrow \\ \Delta^n & \xrightarrow{\sigma_\alpha} & \mathcal{D}_{\alpha+1} . \end{array}$$

In what follows, we will identify σ_α with an n -simplex of $\mathcal{D}$ and write τ_α for its i th face $d_i^n(\sigma_\alpha)$.

- For every nonzero limit ordinal $\lambda \leq \beta$, the comparison map $\varinjlim_{\alpha < \lambda} \mathcal{D}_\alpha \rightarrow \mathcal{D}_\lambda$ is an isomorphism.

Let us say that a simplicial subset $S \subseteq \mathcal{D}$ is *saturated* if, whenever S contains the simplex τ_α , then it also contains the simplex σ_α . If S is any simplicial subset of $\mathcal{D}$, then there is a smallest saturated simplicial subset S^+ which contains S . Moreover, if S is finite, then S^+ is also finite.

Since U is an inner fibration, $\mathcal{D}$ is an ∞ -category. Since U_0 and j are categorical equivalences of simplicial sets, the functor U is an equivalence of ∞ -categories, and therefore admits a homotopy inverse $U^{-1} : \mathcal{C} \rightarrow \mathcal{D}$. Let $L \subseteq \mathcal{D}$ be the smallest saturated simplicial subset which contains both $\mathcal{D}_0$ and the image of the diagram $(U^{-1} \circ f_0) : K_0 \rightarrow \mathcal{D}$. For $\alpha \leq \beta$, set $L_\alpha = L \cap \mathcal{D}_\alpha$. Then the inclusion map $\mathcal{D}_0 = L_0 \hookrightarrow L_\beta = L$ can be realized as a transfinite composition of morphisms $L_\alpha \hookrightarrow L_{\alpha+1}$, each of which is either a pushout of an

inner horn inclusion (if the simplex σ_α is contained in L) or an isomorphism (if σ_α is not contained in L). In particular, the inclusion $\mathcal{D}_0 \hookrightarrow L$ is inner anodyne, so that $U|_L : L \rightarrow \mathcal{C}$ is a categorical equivalence of simplicial sets.

By construction, the composition $U^{-1} \circ f_0$ can be regarded as a morphism of simplicial sets $g : K_0 \rightarrow L$. Set $f_1 = U|_L \circ g$. Since U^{-1} is a homotopy inverse to U , f_0 and f_1 are isomorphic when regarded as objects of the ∞ -category $\text{Fun}(K, \mathcal{C})$. Let Q be a finite simplicial set equipped with a monomorphism $e : \Delta^1 \hookrightarrow Q$ which exhibits Q as a localization of Δ^1 with respect to its nondegenerate edge (for example, we can take Q to be the quotient of Δ^3 appearing in Corollary 6.3.2.8). Let q_0 and q_1 be the vertices of Q given by the source and target of the edge e . Our assumption that f_0 and f_1 are isomorphic is then equivalent to the assertion that there exists a diagram $h : Q \rightarrow \text{Fun}(K_0, \mathcal{C})$ satisfying $h(q_0) = f_0$ and $h(q_1) = f_1$. Let us identify h with a morphism of simplicial sets $H : Q \times K_0 \rightarrow \mathcal{C}$.

Note that the projection map $Q \rightarrow \Delta^0$ is a categorical equivalence of simplicial sets (see Corollary 6.3.2.7), so the inclusion $\{q_1\} \hookrightarrow Q$ has the same property. Form a pushout diagram

$$\begin{array}{ccc} \{q_1\} \times K_0 & \xrightarrow{g} & L \\ \downarrow & & \downarrow \\ Q \times K_0 & \longrightarrow & K, \end{array}$$

so that the left vertical map determines a categorical equivalence $L \hookrightarrow K$ (Remark 4.5.4.13). By construction, there is a unique morphism of simplicial sets $f : K \rightarrow \mathcal{C}$ satisfying $f|_L = U|_L$ and $f|_{(Q \times K_0)} = H$. Since $U|_L$ is a categorical equivalence, it follows that f is a categorical equivalence. We conclude by observing that f_0 can be recovered as the composition $f \circ u$, where u is the monomorphism given by the composition

$$K_0 \simeq \{q_0\} \times K_0 \hookrightarrow Q \times K_0 \rightarrow K.$$

□

0688 Proposition 9.2.7.3. *Let $\mathcal{C}$ be an essentially finite ∞ -category and let W be a finite collection of morphisms of $\mathcal{C}$. Then the localization $\mathcal{C}[W^{-1}]$ is also essentially finite.*

Proof. Choose a categorical equivalence $F : \mathcal{C}_0 \rightarrow \mathcal{C}$, where $\mathcal{C}_0$ is a finite simplicial set. By virtue of Lemma 9.2.7.2, we can assume that $W = F(W_0)$, where W_0 is a collection of morphisms of $\mathcal{C}_0$. In this case, we can identify $\mathcal{C}[W^{-1}]$ with a localization of $\mathcal{C}_0$ with respect to W_0 , which is essentially finite by virtue of Remark 6.3.2.10. □

Definitions 9.2.7.1 and 9.2.6.1 are compatible with one another:

Proposition 9.2.7.4. *Let X be a Kan complex. The following conditions are equivalent:* 0689

- (1) *The Kan complex X is essentially finite in the sense of Definition 9.2.6.1: that is, there exists a finite simplicial set K and a weak homotopy equivalence $f : K \rightarrow X$.*
- (2) *The Kan complex X is essentially finite when viewed as an ∞ -category, in the sense of Definition 9.2.7.1: that is, there exists a finite simplicial set K and a categorical equivalence $K \rightarrow X$.*

Proof. The implication (2) $\Rightarrow$ (1) is trivial, since every categorical equivalence of simplicial sets is a weak homotopy equivalence (Remark 4.5.3.4). We now prove the converse. Assume that there exists a weak homotopy equivalence $f : K \rightarrow X$, where K is a finite simplicial set. Then f factors as a composition $K \xrightarrow{i} \mathcal{C} \xrightarrow{F} X$, where $\mathcal{C}$ is an ∞ -category and i is a categorical equivalence of simplicial sets (Proposition 4.1.3.2). Let W be the collection of all edges of K . Since f is a weak homotopy equivalence, it exhibits the Kan complex X as a localization of K with respect to W (Proposition 6.3.1.21). It follows that the functor F exhibits X as a localization of $\mathcal{C}$ with respect to $i(W)$. Since $\mathcal{C}$ is an essentially finite ∞ -category, Proposition 9.2.7.3 implies that X is also an essentially finite ∞ -category. $\square$

Remark 9.2.7.5. Let $\mathcal{C}$ be an ∞ -category. Choose a weak homotopy equivalence $F : \mathcal{C} \rightarrow X$, 068A where X is a Kan complex (for example, we could take $X = \text{Ex}^\infty(\mathcal{C})$). Suppose that $\mathcal{C}$ is essentially finite: that is, that there exists a categorical equivalence of simplicial sets $G : K \rightarrow \mathcal{C}$. Then the composite map $(G \circ F) : K \rightarrow X$ is a weak homotopy equivalence, so that X is an essentially finite when regarded as a Kan complex. It follows from Proposition 9.2.7.4 that X is also essentially finite when regarded as an ∞ -category.

Proposition 9.2.7.6. *Suppose we are given a categorical pushout diagram of ∞ -categories* 068B

$$\begin{array}{ccc} \mathcal{C} & \longrightarrow & \mathcal{C}_0 \\ \downarrow & & \downarrow \\ \mathcal{C}_1 & \longrightarrow & \mathcal{C}_{01} \end{array} \quad (9.8) \quad 068C$$

If $\mathcal{C}$, $\mathcal{C}_0$, and $\mathcal{C}_1$ are essentially finite, then $\mathcal{C}_{01}$ is essentially finite.

Proof. Using Lemma 9.2.7.2, we can construct a commutative diagram of simplicial sets

$$\begin{array}{ccccc} K_0 & \longleftarrow & K & \longrightarrow & K_1 \\ \downarrow & & \downarrow & & \downarrow \\ \mathcal{C}_0 & \longleftarrow & \mathcal{C} & \longrightarrow & \mathcal{C}_1 \end{array}$$

where the vertical maps are categorical equivalences, the upper horizontal maps are monomorphisms, and the simplicial sets K_0 , K , and K_1 are finite. Our assumption that (9.8) is a categorical pushout square then guarantees that the induced map $K_0 \amalg_K K_1 \rightarrow \mathcal{C}_{01}$ is a categorical equivalence (Proposition 4.5.4.9), so that the ∞ -category $\mathcal{C}_{01}$ is also essentially finite. $\square$

068D **Corollary 9.2.7.7.** *The collection of essentially finite ∞ -categories is closed under the formation of finite colimits (formed in the ∞ -category $\mathcal{QC}$).*

Proof. Since the initial object $\emptyset \in \mathcal{QC}$ is essentially finite, it will suffice to show that essential finiteness is closed under the formation of pushouts (see Corollary 7.6.2.30). This is a reformulation of Proposition 9.2.7.6 (see Example 7.6.3.4). $\square$

068E **Proposition 9.2.7.8.** *Let $\mathcal{QC}_{\text{fin}}$ denote the smallest full subcategory of $\mathcal{QC}$ which is closed under finite colimits and contains Δ^1 . Then an ∞ -category $\mathcal{C}$ belongs to $\mathcal{QC}_{\text{fin}}$ if and only if it is essentially finite.*

Proof. For every simplicial set K , we can choose a categorical equivalence $K \rightarrow \mathcal{C}$, where $\mathcal{C}$ is an ∞ -category. Let us say that K is *good* if the ∞ -category $\mathcal{C}$ belongs to $\mathcal{QC}_{\text{fin}}$ (note that this condition is invariant under equivalence, and therefore depends only on K). We will show that every finite simplicial set K is good: that is, every essentially finite ∞ -category belongs to $\mathcal{QC}_{\text{fin}}$; the converse is an immediate consequence of Corollary 9.2.7.7. Our proof proceeds in several steps:

- (a) The simplicial set Δ^1 is good (since it is an ∞ -category which belongs to $\mathcal{QC}_{\text{fin}}$).
- (b) Let $f : K \rightarrow K'$ be a categorical equivalence of simplicial sets. Then K is good if and only if K' is good.
- (c) The collection of good simplicial sets is closed under finite coproducts (since $\mathcal{QC}_{\text{fin}}$ is closed under finite coproducts in $\mathcal{QC}$; see Corollary 4.5.3.10 and Example 7.6.1.17).
- (d) Suppose we are given a categorical pushout square of simplicial sets

$$\begin{array}{ccc} K_{01} & \longrightarrow & K_0 \\ \downarrow & & \downarrow \\ K_1 & \longrightarrow & K. \end{array}$$

If K_0 , K_1 , and K_{01} are good, then K is good. See Example 7.6.3.5.

- (e) Let (K, x) and (K', x') be pointed simplicial sets and let $K \vee K'$ denote the pushout $K \amalg_{\Delta^0} K'$. If K and K' are good, then $K \vee K'$ is also good. To prove this, consider the diagram

$$\begin{array}{ccccc}
 \Delta^1 \amalg \Delta^1 & \longrightarrow & \{x\} \amalg \{x'\} & \longrightarrow & K \amalg K' \\
 \downarrow & & \downarrow & & \downarrow \\
 \Delta^1 & \longrightarrow & \Delta^0 & \longrightarrow & K \vee K'.
 \end{array}$$

The right half of the diagram is a pushout square in which the horizontal maps are monomorphisms, and therefore a categorical pushout square (Example 4.5.4.12). The left half of the diagram is a categorical pushout square by virtue of Proposition 6.3.2.4. Applying Proposition 4.5.4.8, we conclude that the outer rectangle is also a categorical pushout square. By virtue of (d), it will suffice to show that the simplicial sets Δ^1 , $\Delta^1 \amalg \Delta^1$, and $K \amalg K'$ are good. This follows from (a) and (b).

- (f) Let n be a positive integer, and let $\text{Spine}[n]$ denote the spine of the standard n -simplex Δ^n (Example 1.5.7.7). Then the simplicial set $\text{Spine}[n]$ is good. For $n = 1$, this follows from (a). The general case follows by induction on n , using (e).
- (g) The standard 0-simplex Δ^0 is good. To prove this, consider the diagram of simplicial sets

$$\begin{array}{ccccc}
 N_{\bullet}(\{0 < 1\}) & \longrightarrow & \text{Spine}[2] & \longrightarrow & \text{Spine}[2]/N_{\bullet}(\{1 < 2\}) \\
 \downarrow & & \downarrow & & \downarrow \\
 \Delta^0 & \longrightarrow & \text{Spine}[2]/N_{\bullet}(\{0 < 1\}) & \longrightarrow & \Delta^0.
 \end{array}$$

The left side and outer rectangle are pushout square in which the horizontal maps are monomorphisms, and therefore categorical pushout squares (Example 4.5.4.12). Applying Proposition 4.5.4.8, we see that the right side is also a categorical pushout square. Using (d), we are reduced to proving that the simplicial set $\text{Spine}[2]$ and its quotients $\text{Spine}[2]/N_{\bullet}(\{0 < 1\})$ and $\text{Spine}[2]/N_{\bullet}(\{1 < 2\})$ are good, which follows from (f).

- (h) For every integer n , the standard n -simplex Δ^n is good. For $n = 0$, this follows from (g). For $n > 0$, it follows from (b) and (f), since the inclusion map $\text{Spine}[n] \hookrightarrow \Delta^n$ is a categorical equivalence (Example 1.5.7.7).

We now show that every finite simplicial set K is good. If K is empty, this follows from (c). We may therefore assume that K has dimension $d \geq 0$. Proceeding by induction on d and on the number of nondegenerate simplices of K , we may assume that there exists a pushout square

$$\begin{array}{ccc} \partial\Delta^d & \longrightarrow & K_0 \\ \downarrow & & \downarrow \\ \Delta^d & \longrightarrow & K, \end{array} \quad (9.9)$$

where the simplicial sets $\partial\Delta^d$ and K_0 are good by our inductive hypothesis, and Δ^d is good by virtue of (h). Since (9.9) is a categorical pushout square (Example 4.5.4.12), it follows from (d) that K is also good. $\square$

068G Proposition 9.2.7.9. *Let $\mathcal{C}$ be an essentially finite ∞ -category. Then $\mathcal{C}$ is compact when regarded as an object of the ∞ -category $\mathcal{QC}$.*

Proof. Let $h^{\mathcal{C}} : \mathcal{QC} \rightarrow \mathcal{S}$ be the functor corepresented by $\mathcal{C}$; we wish to show that the functor $h^{\mathcal{C}}$ is finitary. By virtue of Corollary 9.2.1.13, it will suffice to show that the functor $h^{\mathcal{C}}$ preserves the colimit of every diagram $\mathcal{F} : N_{\bullet}(A) \rightarrow \mathcal{QC}$ indexed by a small directed partially ordered set $(A, \leq)$. Using Corollary 5.6.5.18, we can reduce to the case where $\mathcal{F}$ factors through the simplicial subset $N_{\bullet}(\mathcal{QCat}) \subset N_{\bullet}^{\text{h}\mathcal{C}}(\mathcal{QCat}) = \mathcal{QC}$: that is, it is given by a diagram in the ordinary category of simplicial sets.

Choose a categorical equivalence $f : K \rightarrow \mathcal{C}$, where K is a finite simplicial set. Using Proposition 5.6.6.17, we can assume that $h^{\mathcal{C}}$ is obtained as the homotopy coherent nerve of the simplicially enriched functor $\text{Fun}(K, \bullet)^{\simeq} : \mathcal{QCat} \rightarrow \text{Kan}$. In particular, we have a commutative diagram of ∞ -categories

$$\begin{array}{ccc} N_{\bullet}(\mathcal{QCat}) & \xrightarrow{\text{Fun}(K, \bullet)^{\simeq}} & N_{\bullet}(\text{Kan}) \\ \downarrow & & \downarrow \\ \mathcal{QC} & \xrightarrow{h^{\mathcal{C}}} & \mathcal{S}. \end{array}$$

Consequently, to show that the functor $h^{\mathcal{C}}$ preserves the colimit of the diagram $\mathcal{F}$, it will suffice to show that the vertical maps and upper horizontal map in this diagram preserve $N_{\bullet}(A)$ -indexed colimits. For the vertical maps, this follows from Corollary 9.1.6.3 and Variant 9.1.6.4. For the upper horizontal map, it follows from Variant 9.2.0.5. $\square$

Beware that the converse of Proposition 9.2.7.9 is false. This motivates the following:

Definition 9.2.7.10. Let $\mathcal{C}$ be an ∞ -category. We say that $\mathcal{C}$ is *finitely dominated* if it is a retract (in the homotopy category hQCat) of an essentially finite ∞ -category. 068J

Remark 9.2.7.11. Let X be a Kan complex. The following conditions are equivalent: 068K

- (1) The Kan complex X is finitely dominated in the sense of Definition 9.2.6.6: that is, it is a retract of an essentially finite Kan complex Y (in the homotopy category hKan).
- (2) The Kan complex X is finitely dominated when regarded as an ∞ -category, in the sense of Definition 9.2.7.10: that is, it is a retract of an essentially finite ∞ -category $\mathcal{C}$ (in the homotopy category hQCat).

The implication (1) $\Rightarrow$ (2) is immediate. For the converse, assume that X is a retract of an essentially finite ∞ -category $\mathcal{C}$. Then X is a retract of the Kan complex $\mathrm{Ex}^\infty(\mathcal{C})$, which is also essentially finite (Remark 9.2.7.5).

Proposition 9.2.7.12. Let $\mathcal{C}$ be a small ∞ -category. Then $\mathcal{C}$ is finitely dominated if and only if it is compact when viewed as an object of the ∞ -category $\mathcal{QC}$. 068L

Proof. If $\mathcal{C}$ is finitely dominated, then it is a retract (in the ∞ -category $\mathcal{QC}$) of an essentially finite ∞ -category $\mathcal{D}$. Since $\mathcal{D}$ is a compact object of $\mathcal{QC}$ (Proposition 9.2.7.9), it follows that $\mathcal{C}$ is also a compact object of $\mathcal{QC}$ (Remark 9.2.5.18).

For the converse, we proceed as in the proof of Proposition 9.2.6.7. Using Proposition 4.1.3.2, we can choose a functor $Q : \mathrm{Set}_\Delta \rightarrow \mathrm{QCat}$ which preserves small filtered colimits, which carries each simplicial set X to an ∞ -category $Q(X)$ equipped with an inner anodyne map $u_X : X \hookrightarrow Q(X)$. Using Corollary 9.1.6.3, we see that the functor

$$N_\bullet(\mathrm{Set}_\Delta) \xrightarrow{Q} N_\bullet(\mathrm{QCat}) \hookrightarrow N_\bullet^{\mathrm{hc}}(\mathrm{QCat}) = \mathcal{QC}$$

also preserves small filtered colimits. If $\mathcal{C}$ is a compact object of $\mathcal{QC}$, it follows that the functor

$$\mathrm{Set}_\Delta \rightarrow \mathrm{Set} \quad X \mapsto \pi_0(\mathrm{Hom}_{\mathcal{QC}}(\mathcal{C}, Q(X))) = \mathrm{Hom}_{\mathrm{hQC}}(\mathcal{C}, Q(X))$$

preserves small sifted colimits. In particular, the equivalence $u_{\mathcal{C}} : \mathcal{C} \rightarrow Q(\mathcal{C})$ factors up to homotopy through $Q(\mathcal{C}_0)$ for some finite simplicial subset $\mathcal{C}_0 \subseteq \mathcal{C}$. It follows that $\mathcal{C}$ is a retract of the essentially finite ∞ -category $Q(\mathcal{C}_0)$, and is therefore finitely dominated. $\square$

Proposition 9.2.7.13. Let $\mathcal{QC}_{<\aleph_0}$ be the ∞ -category of finitely dominated ∞ -categories. Then $\mathcal{QC}_{<\aleph_0}$ is essentially $\aleph_1$ -small: that is, it is equivalent to an ∞ -category having finitely many simplices. 06ET

Proof. By virtue of Proposition 8.5.5.7, it will suffice to show that the ∞ -category $\mathcal{QC}_{\mathrm{fin}}$ is essentially $\aleph_1$ -small. Since the collection of isomorphism classes of finite simplicial sets

is countable (Variant 4.7.4.21), the collection of isomorphism classes of objects of $\mathcal{QC}_{\text{fin}}$ is also countable. It will therefore suffice to show that the ∞ -category $\mathcal{QC}_{\text{fin}}$ is locally $\aleph_1$ -small. Let $\mathcal{C}$ and $\mathcal{D}$ be essentially finite ∞ -categories; we wish to show that the morphism space $\text{Hom}_{\mathcal{QC}}(\mathcal{C}, \mathcal{D}) \simeq \text{Fun}(\mathcal{C}, \mathcal{D})^\simeq$ is essentially $\aleph_1$ -small (see Remark 5.5.4.5). Without loss of generality, we may assume that $\mathcal{D}$ is $\aleph_1$ -small. Since $\mathcal{C}$ is essentially finite, there is a categorical equivalence $e : K \rightarrow \mathcal{C}$, where K is a finite simplicial set. Then composition with e induces a homotopy equivalence from $\text{Fun}(\mathcal{C}, \mathcal{D})^\simeq$ to the Kan complex $\text{Fun}(K, \mathcal{D})^\simeq$, which is $\aleph_1$ -small by virtue of Corollary 4.7.4.19. $\square$

The infinitary counterpart of Proposition 9.2.7.12 is more straightforward.

068N Proposition 9.2.7.14. *Let κ be an uncountable regular cardinal and let $\mathcal{C}$ be an ∞ -category. The following conditions are equivalent:*

- (1) *The ∞ -category $\mathcal{C}$ is essentially κ -small (Definition 4.7.5.1).*
- (2) *The ∞ -category $\mathcal{C}$ belongs to the smallest full subcategory of $\mathcal{QC}$ which contains Δ^1 and is closed under κ -small colimits.*
- (3) *The ∞ -category $\mathcal{C}$ is κ -compact when viewed as an object of the ∞ -category $\mathcal{QC}$.*

In the formulation of Proposition 9.2.7.14, we have implicitly assumed that the cardinal κ and the ∞ -category $\mathcal{C}$ are κ -small. Following the convention of Remark 4.7.0.5, we can regard Proposition 9.2.7.14 as a special case of the following more precise assertion:

068P Proposition 9.2.7.15. *Let $\kappa \leq \lambda$ be uncountable regular cardinals and let $\mathcal{C}$ be a λ -small ∞ -category. The following conditions are equivalent:*

- (1) *The ∞ -category $\mathcal{C}$ is essentially κ -small.*
- (2) *The ∞ -category $\mathcal{C}$ belongs to the smallest full subcategory of $\mathcal{QC}_{<\lambda}$ which contains Δ^1 and is closed under κ -small colimits.*
- (3) *The ∞ -category $\mathcal{C}$ is (κ, λ) -compact when viewed as an object of the ∞ -category $\mathcal{QC}_{<\lambda}$.*

Proof. Let $\mathcal{E} \subseteq \mathcal{QC}_{<\lambda}$ be the smallest full subcategory which contains Δ^1 and is closed under κ -small colimits. Applying Proposition 9.2.7.8, we conclude that every essentially finite ∞ -category belongs to $\mathcal{E}$. Let $Q : \text{Set}_\Delta \rightarrow \text{QCat}$ be as in the proof of Proposition 9.2.7.12. If $\mathcal{C}$ is a κ -small simplicial set, then it can be realized as the colimit of a κ -small filtered diagram $\{\mathcal{C}_\alpha\}$ of finite simplicial sets $\mathcal{C}_\alpha$, so that $Q(\mathcal{C})$ is the colimit of a κ -small filtered diagram $\{Q(\mathcal{C}_\alpha)\}$ in the ∞ -category $\mathcal{QC}_{<\lambda}$. Since each $Q(\mathcal{C}_\alpha)$ is essentially finite, it follows that $Q(\mathcal{C})$ belongs to $\mathcal{E}$. If $\mathcal{C}$ is an ∞ -category, then it is equivalent to $Q(\mathcal{C})$ and therefore also belongs to $\mathcal{E}$. This establishes the implication (1) $\Rightarrow$ (2).

The implication (2) $\Rightarrow$ (3) follows from Proposition 9.2.5.23. We will complete the proof by showing that (3) implies (1). Using Variant 9.1.7.21, we can write $\mathcal{C}$ as the colimit of a diagram

$$(A, \leq) \rightarrow \mathbf{QCat} \quad \alpha \mapsto \mathcal{C}_\alpha,$$

where $(A, \leq)$ is a λ -small κ -directed partially ordered set and each $\mathcal{C}_\alpha$ is a κ -small ∞ -category. Corollary 9.1.6.3 implies that $\mathcal{C}$ is also the colimit of the diagram $\{\mathcal{C}_\alpha\}$ in the ∞ -category $\mathbf{QC}_{<\lambda}$. If $\mathcal{C}$ is a (κ, λ) -compact object of $\mathbf{QC}_{<\lambda}$, it follows that the identity functor $\mathrm{id}_{\mathcal{C}}$ factors up to homotopy through some $\mathcal{C}_\alpha$. In particular, $\mathcal{C}$ is a retract of $\mathcal{C}_\alpha$, and can therefore be realized as the colimit of a diagram

$$\mathcal{C}_\alpha \xrightarrow{e} \mathcal{C}_\alpha \xrightarrow{e} \mathcal{C}_\alpha \xrightarrow{e} \mathcal{C}_\alpha \rightarrow \cdots$$

in the ∞ -category $\mathcal{S}_{<\lambda}$, for some (homotopy idempotent) endomorphism e of the ∞ -category $\mathcal{C}_\alpha$. Forming the colimit of this diagram in the ordinary category of simplicial sets, we obtain a κ -small ∞ -category which is equivalent to $\mathcal{C}$ (Corollary 9.1.6.3). $\square$

9.2.8 Closure Properties of Compact Objects

Let $\mathcal{C}$ be an ∞ -category which admits small filtered colimits. In this section, we collect some elementary results which can be used to establish the compactness of an object $C \in \mathcal{C}$. Our starting point is the following: 06EU

Proposition 9.2.8.1 (Compactness in Oriented Fiber Products). *Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}_-$, $\mathcal{C}_+$, and $\mathcal{C}$ be ∞ -categories which are (κ, λ) -cocomplete, and let $F_- : \mathcal{C}_- \rightarrow \mathcal{C}$ and $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$ be functors which are (κ, λ) -finitary. Then:* 06EV

- (1) *The oriented fiber product $\mathcal{C}_\pm = \mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ is (κ, λ) -cocomplete, and the projection maps $\mathcal{C}_- \xleftarrow{\mathrm{ev}_-} \mathcal{C}_\pm \xrightarrow{\mathrm{ev}_+} \mathcal{C}_+$ are (κ, λ) -finitary.*
- (2) *Let C be an object of $\mathcal{C}_\pm$, given by a triple (C_-, C_+, u) where C_- is an object of $\mathcal{C}_-$, C_+ is an object of $\mathcal{C}_+$, and $u : F_-(C_-) \rightarrow F_+(C_+)$ is a morphism in $\mathcal{C}$. If C_- , C_+ , and $F_-(C_-)$ are (κ, λ) -compact (as objects of $\mathcal{C}_-$, $\mathcal{C}_+$, and $\mathcal{C}$, respectively), then C is a (κ, λ) -compact object of $\mathcal{C}_\pm$.*

Remark 9.2.8.2. In the situation of Proposition 9.2.8.1, it is not necessary to assume that $F_+(C_+)$ is a (κ, λ) -compact object of $\mathcal{C}$. 06EW

Proof of Proposition 9.2.8.1. Assertion (1) follows from Corollary 7.1.9.5 (and does not require the assumption that F_+ is (κ, λ) -finitary). We will prove (2). Fix an uncountable cardinal μ of cofinality $\geq \lambda$ such that $\mathcal{C}_-$, $\mathcal{C}_+$, and $\mathcal{C}$ are locally μ -small. We must show that the corepresentable functor $h^C : \mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+ \rightarrow \mathcal{S}_{<\mu}$ is (κ, λ) -finitary. Let $h^{C_-} : \mathcal{C}_- \rightarrow \mathcal{S}_{<\mu}$, $h^{C_+} : \mathcal{C}_+ \rightarrow \mathcal{S}_{<\mu}$ and $h^{F_-(C_-)} : \mathcal{C} \rightarrow \mathcal{S}_{<\mu}$ denote functors corepresented by C_- , C_+ , and

$F_-(C_-)$, respectively. Let $\text{ev}_- : \mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+ \rightarrow \mathcal{C}_-$ and $\text{ev}_+ : \mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+ \rightarrow \mathcal{C}_+$ be the projection maps. Applying Theorem 8.3.7.1 (and Remark 8.3.7.2), we obtain a (levelwise) pullback diagram

$$\begin{array}{ccc} h^C & \xrightarrow{\quad} & h^{C_+} \circ \text{ev}_+ \\ \downarrow & & \downarrow \\ h^{C_-} \circ \text{ev}_- & \xrightarrow{\quad} & h^{F_-(C_-)} \circ F_+ \circ \text{ev}_+ \end{array}$$

in the ∞ -category $\text{Fun}(\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+, \mathcal{S}_{<\mu})$. Since the collection of (κ, λ) -finitary functors from $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ to $\mathcal{S}_{<\mu}$ is closed under κ -small limits, it will suffice to show that the functors $h^{C_+} \circ \text{ev}_+$, $h^{C_-} \circ \text{ev}_-$, and $h^{F_-(C_-)} \circ F_+ \circ \text{ev}_+$ are (κ, λ) -finitary. Since the functors ev_- , ev_+ , and F_+ are (κ, λ) -finitary (Corollary 7.1.9.5), this follows from our assumption that the objects C_- , C_+ , and $F_-(C_-)$ are (κ, λ) -compact. $\square$

06EX Corollary 9.2.8.3 (Compactness in Homotopy Fiber Products). *Let $\kappa \leq \lambda$ be regular cardinals and suppose we are given a categorical pullback diagram of ∞ -categories*

06EY

$$\begin{array}{ccc} \mathcal{C}_{\pm} & \xrightarrow{E_+} & \mathcal{C}_+ \\ \downarrow E_- & & \downarrow F_+ \\ \mathcal{C}_- & \xrightarrow{F_-} & \mathcal{C} \end{array} \quad (9.10)$$

Assume that the ∞ -categories $\mathcal{C}_+$, $\mathcal{C}_-$, and $\mathcal{C}$ are (κ, λ) -cocomplete and that the functors F_- and F_+ are (κ, λ) -finitary (so that $\mathcal{C}_{\pm}$ is (κ, λ) -cocomplete and the functors E_+ and E_- are (κ, λ) -finitary; see Proposition 9.1.9.8). Let $C \in \mathcal{C}_{\pm}$ be an object whose images in $\mathcal{C}_+$, $\mathcal{C}_-$, and $\mathcal{C}$ are (κ, λ) -compact. Then C is (κ, λ) -compact.

Proof. Our assumption that (9.10) is a categorical pullback square guarantees that E_- and E_+ induce an equivalence of ∞ -categories $E : \mathcal{C}_{\pm} \rightarrow \mathcal{C}_- \times_{\mathcal{C}}^h \mathcal{C}_+$. It will therefore suffice to show that $E(C)$ is (κ, λ) -compact when viewed as an object of the homotopy fiber product $\mathcal{C}_- \times_{\mathcal{C}}^h \mathcal{C}_+$. In fact, $E(C)$ is even (κ, λ) -compact when viewed as an object of the oriented fiber product $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$, by virtue of Proposition 9.2.8.1. $\square$

06EZ Proposition 9.2.8.4 (Compactness in Products). *Let $\kappa \leq \lambda$ be regular cardinals, let $\{\mathcal{C}_i\}_{i \in I}$ be a collection of (κ, λ) -cocomplete ∞ -categories, and let $C = \{C_i\}_{i \in I}$ be an object of the product $\mathcal{C} = \prod_{i \in I} \mathcal{C}_i$. If C is a (κ, λ) -compact object of $\mathcal{C}$, then each C_i is a (κ, λ) -compact object of $\mathcal{C}_i$. The converse holds if the index set I is κ -small.*

Proof. Fix an uncountable cardinal μ such that each of the ∞ -categories $\mathcal{C}_i$ is locally μ -small. Then, for each index $i \in I$, we can choose a functor $\mathcal{F}_i : \mathcal{C}_i \rightarrow \mathcal{S}_{<\mu}$ and a vertex $\eta_i \in \mathcal{F}_i(\mathcal{C}_i)$ which exhibits the functor $\mathcal{F}_i$ as corepresented by the object $\mathcal{C}_i$ (see Definition 5.6.6.1). Enlarging μ if necessary, we may assume that it has cofinality $\geq \lambda$ and exponential cofinality larger than the cardinality of I , so that the ∞ -category $\text{Fun}(\mathcal{C}, \mathcal{S}_{<\mu})$ admits λ -small colimits and I -indexed products (see Corollary 7.4.3.10, Variant 7.4.1.15 and Proposition 7.1.8.2). We can therefore choose a functor $\mathcal{F} : \mathcal{C} \rightarrow \mathcal{S}_{<\mu}$ and a collection of natural transformations $u_i : \mathcal{F} \rightarrow \mathcal{F}_i|_{\mathcal{C}}$ which exhibit $\mathcal{F}$ as a product of the collection $\{\mathcal{F}_i|_{\mathcal{C}}\}_{i \in I}$ in the ∞ -category $\text{Fun}(\mathcal{C}, \mathcal{S}_{<\mu})$. It follows that the natural transformations u_i induce a homotopy equivalence of Kan complexes $\mathcal{F}(C) \rightarrow \prod_{i \in I} \mathcal{F}_i(C_i)$ (see Example 7.6.1.16). We may therefore assume without loss of generality that the collection $\{\eta_i\}_{i \in I}$ is the image of some vertex $\eta \in \mathcal{F}(C)$. Using Remark 4.6.1.9, we see that η exhibits the functor $\mathcal{F}$ as corepresented by C .

Assume first that C is a (κ, λ) -compact object of $\mathcal{C}$ and let i be an element of I ; we wish to show that $\mathcal{C}_i$ is a (κ, λ) -compact object of $\mathcal{C}_i$. Let $\delta : \mathcal{C}_i \rightarrow \mathcal{C}$ be the functor given by the identity map $\text{id} : \mathcal{C}_i \rightarrow \mathcal{C}_i$ together with the constant functors $\mathcal{C}_i \rightarrow \{C_j\} \hookrightarrow \mathcal{C}_j$ for $j \neq i$. Our assumption that C is (κ, λ) -compact guarantees that the composite functor

$$\mathcal{C}_i \xrightarrow{\delta} \mathcal{C} \xrightarrow{\mathcal{F}} \mathcal{S}_{<\mu}$$

is (κ, λ) -finitary. This composite functor can be identified with the product of $\mathcal{F}_i$ with the constant functor $\mathcal{C}_i \rightarrow \mathcal{S}_{<\mu}$ taking the value $X = \prod_{j \neq i} \mathcal{F}_j(C_j)$. Since the Kan complex X is nonempty (it contains the vertex $\{\eta_j\}_{j \neq i}$), it follows that $\mathcal{F}_i$ is a retract of $\delta \circ \mathcal{F}$ and is therefore also (κ, λ) -finitary (Remark 9.2.2.13).

We now prove the converse. Assume that each $\mathcal{C}_i$ is (κ, λ) -compact as an object of $\mathcal{C}_i$. Then each of the functors $\mathcal{F}_i$ is (κ, λ) -finitary, and therefore restricts to a (κ, λ) -finitary functor $\mathcal{F}_i|_{\mathcal{C}} : \mathcal{C} \rightarrow \mathcal{S}_{<\mu}$ (Proposition 9.1.9.8). If I is κ -small, then the formation of I -indexed products commutes with λ -small κ -filtered colimits in the ∞ -category $\mathcal{S}_{<\mu}$ (Theorem 9.1.5.9), so the functor $\mathcal{F} = \prod_{i \in I} \mathcal{F}_i|_{\mathcal{C}}$ is also (κ, λ) -finitary: that is, the object $C \in \mathcal{C}$ is (κ, λ) -compact. $\square$

Corollary 9.2.8.5 (Compactness in Sequential Limits). *Let $\kappa \leq \lambda$ be uncountable regular cardinals and suppose we are given a tower of ∞ -categories*

$$\cdots \rightarrow \mathcal{C}_3 \xrightarrow{U_2} \mathcal{C}_2 \xrightarrow{U_1} \mathcal{C}_1 \xrightarrow{U_0} \mathcal{C}_0.$$

Assume that:

- *Each of the ∞ -categories $\mathcal{C}_n$ is (κ, λ) -cocomplete.*
- *Each of the functors $U_n : \mathcal{C}_{n+1} \rightarrow \mathcal{C}_n$ is (κ, λ) -finitary.*
- *Each of the functors U_n is an isofibration, so that the inverse limit $\varprojlim (\mathcal{C}_n)$.*

Let C be an object of the inverse limit $\varprojlim \mathcal{C}_n$, given by a sequence of objects $\{C_n \in \mathcal{C}_n\}$ satisfying $F_n(C_{n+1}) = C_n$. If each C_n is a (κ, λ) -compact object of $\mathcal{C}_n$, then C is (κ, λ) -compact object of $\varprojlim(\mathcal{C}_n)$.

Proof. Set $\mathcal{C} = \prod_n \mathcal{C}_n$, and let $S : \mathcal{C} \rightarrow \mathcal{C}$ be the shift functor (given on objects by the construction $\{D_n\}_{n \geq 0} \mapsto \{U_n(D_{n+1})\}_{n \geq 0}$). By virtue of Corollary 4.5.6.19, the diagram of ∞ -categories

$$\begin{array}{ccc} \varprojlim \mathcal{C}_n & \xrightarrow{\quad} & \mathcal{C} \\ \downarrow & & \downarrow (\text{id}, \text{id}) \\ \mathcal{C} & \xrightarrow{(\text{id}, S)} & \mathcal{C} \times \mathcal{C} \end{array}$$

is a categorical pullback square, in which the maps are given by (κ, λ) -finitary functors. By virtue of Corollary 9.2.8.3, to show that the sequence $C = \{C_n\}_{n \geq 0}$ is (κ, λ) -compact as an object of the inverse limit $\varprojlim(\mathcal{C}_n)$, it will suffice to show that it is (κ, λ) -compact when viewed as an object of $\mathcal{C}$ and that (C, C) is (κ, λ) -compact when viewed as an object of $\mathcal{C} \times \mathcal{C}$. Both assertions follow from Proposition 9.2.8.4 (since κ is uncountable and each C_n is a (κ, λ) -compact object of $\mathcal{C}_n$). $\square$

06F1 Warning 9.2.8.6. In the statement of Corollary 9.2.8.5, the assumption that κ is uncountable cannot be omitted.

06F2 Proposition 9.2.8.7 (Compactness in Diagram ∞ -Categories). *Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete, and let K be a simplicial set. Then:*

- (1) *The diagram ∞ -category $\text{Fun}(K, \mathcal{C})$ is (κ, λ) -cocomplete.*
- (2) *Let $F : K \rightarrow \mathcal{C}$ be a diagram. If K is κ -small and $F(k) \in \mathcal{C}$ is (κ, λ) -compact for each vertex $k \in K$, then F is (κ, λ) -compact as an object of $\text{Fun}(K, \mathcal{C})$.*

Proof. Assertion (1) follows from Proposition 7.1.8.2. We will prove (2). Let $F : K \rightarrow \mathcal{C}$ be a diagram having the property that, for each vertex $k \in K$, the object $F(k) \in \mathcal{C}$ is (κ, λ) -compact. If K' is a simplicial set with a map $K' \rightarrow K$, we will say that K' is *good* if $F|_{K'}$ is (κ, λ) -compact when viewed as an object of the ∞ -category $\text{Fun}(K', \mathcal{C})$. To complete the proof, it will suffice to show that if K' is κ -small, then it is good.

Note that $\text{Fun}(K', \mathcal{C})$ can be realized as the inverse limit of a tower of ∞ -categories

$$\cdots \rightarrow \text{Fun}(\text{sk}_2(K'), \mathcal{C}) \rightarrow \text{Fun}(\text{sk}_1(K'), \mathcal{C}) \rightarrow \text{Fun}(\text{sk}_0(K'), \mathcal{C}),$$

where the transition maps are isofibrations (Corollary 4.4.5.3). Each of the ∞ -categories appearing in this tower is (κ, λ) -cocomplete and each of the transition functors is (κ, λ) -finitary. It will therefore suffice to show that each of the skeleta $\mathrm{sk}_n(K')$ is good: this is immediate if $\kappa = \aleph_0$ (the assumption that K' is finite guarantees that it coincides with $\mathrm{sk}_n(K')$ for $n \gg 0$), and follows from Corollary 9.2.8.5 when $\kappa > \aleph_0$. We may therefore replace K' by $\mathrm{sk}_n(K')$ and thereby reduce to the case where the simplicial set K has dimension $\leq n$, for some integer $n \geq -1$.

We now proceed by induction on n . If $n = -1$, then the simplicial set K' is empty and the result is clear. Otherwise, let $K'' = \mathrm{sk}_{n-1}(K')$ be the $(n-1)$ -skeleton of K and let S be the collection of all nondegenerate n -simplices of K' (which is κ -small, by virtue of our assumption that K' is κ -small). Applying Proposition 1.1.4.12, we obtain a pullback diagram of ∞ -categories

$$\begin{array}{ccc} \mathrm{Fun}(K', \mathcal{C}) & \xrightarrow{\quad} & \mathrm{Fun}(K'', \mathcal{C}) \\ \downarrow & & \downarrow \\ \prod_{\sigma \in S} \mathrm{Fun}(\Delta^n, \mathcal{C}) & \xrightarrow{\quad} & \prod_{\sigma \in S} \mathrm{Fun}(\partial\Delta^n, \mathcal{C}). \end{array}$$

Since the horizontal maps in this diagram are isofibrations (Corollary 4.4.5.3), it is also a categorical pullback square (Corollary 4.5.2.28). Moreover, each of the ∞ -categories in the diagram is (κ, λ) -cocomplete and the transition functors are (κ, λ) -finitary. Combining our inductive hypothesis, Corollary 9.2.8.3, and Proposition 9.2.8.4, we can reduce to the case where $K' = \Delta^n$ is a standard simplex.

If $n = 0$, the desired result follows from our assumption that F carries vertices of K to (κ, λ) -compact objects of $\mathcal{C}$. If $n = 1$, then we can identify $\mathrm{Fun}(K', \mathcal{C})$ with the oriented fiber product $\mathcal{C} \tilde{\times}_{\mathcal{C}} \mathcal{C}$, and the desired result follows from Proposition 9.2.8.1. We may therefore assume that $n \geq 2$. Let $\mathrm{Spine}[n] \subseteq \Delta^n$ be as in Example 1.5.7.7. The inclusion $\mathrm{Spine}[n] \hookrightarrow \Delta^n$ is inner anodyne and therefore induces a trivial Kan fibration $\mathrm{Fun}(\Delta^n, \mathcal{C}) \rightarrow \mathrm{Fun}(\mathrm{Spine}[n], \mathcal{C})$. The desired result now follows from our inductive hypothesis, since the simplicial set $\mathrm{Spine}[n]$ has dimension 1. $\square$

Warning 9.2.8.8. The converse of Proposition 9.2.8.7 is false in general. For example, let $K = \Delta^1 / \partial\Delta^1$ be the simplicial circle (Example 1.5.7.11) and let $\mathcal{C}$ be (the nerve of) the category $\mathbf{Ab}$ of abelian groups. Then $\mathrm{Fun}(K, \mathcal{C})$ can be identified with (the nerve of) the category of pairs (M, u) , where M is an abelian group and $u : M \rightarrow M$ is an endomorphism of M . In this case, (M, u) is a compact object of $\mathcal{C}$ if and only if M is finitely generated as a module over the polynomial ring $\mathbf{Z}[u]$. (see Proposition 9.2.0.1). This condition does not guarantee that M is finitely generated as an abelian group (for example, the polynomial ring $\mathbf{Z}[u]$ itself is not finitely generated as an abelian group). 06F3

06F4 **Corollary 9.2.8.9** (Compactness in Slice ∞ -Categories). *Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be a (κ, λ) -cocomplete ∞ -category, and let $F : K \rightarrow \mathcal{C}$ be a κ -small diagram. Then:*

- (1) *If X is an object of the slice ∞ -category $\mathcal{C}_{/F}$ whose image in $\mathcal{C}$ is (κ, λ) -compact, then X is (κ, λ) -compact as an object of $\mathcal{C}_{/F}$.*
- (2) *Suppose that F carries each vertex of K to a (κ, λ) -compact object of $\mathcal{C}$. If Y is an object of the coslice ∞ -category $\mathcal{C}_{F/}$ whose image in $\mathcal{C}$ is (κ, λ) -compact, then Y is (κ, λ) -compact as an object of $\mathcal{C}_{F/}$.*

Proof. Theorem 4.6.4.19 supplies equivalences of ∞ -categories

$$\mathcal{C}_{/F} \hookrightarrow \mathcal{C} \tilde{\times}_{\mathrm{Fun}(K, \mathcal{C})} \{F\} \quad \mathcal{C}_{F/} \hookrightarrow \{F\} \tilde{\times}_{\mathrm{Fun}(K, \mathcal{C})} \mathcal{C}.$$

The desired results now follow by combining Propositions 9.2.8.7 and 9.2.8.1. $\square$

9.2.9 Compactness in ∞ -Categories of Sections

06F5 Let $\mathcal{C}$ be a simplicial set and let $\mathcal{D}$ be an ∞ -category which is given as the limit of an $\mathcal{C}$ -indexed diagram $\{\mathcal{D}_C\}_{C \in \mathcal{C}}$. If each of the ∞ -categories $\mathcal{D}_C$ admits small filtered colimits and each of the transition functors $\mathcal{D}_C \rightarrow \mathcal{D}_{C'}$ preserves small filtered colimits, then the ∞ -category $\mathcal{D}$ also admits small filtered colimits, which are computed levelwise (see Proposition 7.6.6.26). The goal in this section is to formulate a criterion which can be used to establish the compactness of an object $D \in \mathcal{D}$. Our main result asserts that, if the simplicial set $\mathcal{C}$ is finite, then it is sufficient to assume that the image of D in each $\mathcal{D}_C$ is compact. This is a special case of the following:

06F6 **Proposition 9.2.9.1.** *Let $\kappa \leq \lambda$ and μ be regular cardinals, where μ is uncountable. Let $\mathcal{D}$ be the limit of a κ -small diagram*

$$\mathcal{F} : \mathcal{C} \rightarrow \mathcal{QC}_{<\mu}^{(\kappa, \lambda)\text{-ccomp}} \quad (C \in \mathcal{C}) \mapsto \mathcal{F}(C).$$

Let $D \in \mathcal{D}$ be an object having the property that, for each $C \in \mathcal{C}$, the image of D in $\mathcal{F}(C)$ is (κ, λ) -compact. Then D is (κ, λ) -compact.

06F7 **Corollary 9.2.9.2.** *Let μ be an uncountable cardinal and let $\mathcal{D}$ be the limit of a finite diagram*

$$\mathcal{F} : \mathcal{C} \rightarrow \mathcal{QC}_{<\mu} \quad (C \in \mathcal{C}) \mapsto \mathcal{F}(C)$$

satisfying the following conditions:

- (1) *For each vertex $C \in \mathcal{C}$, the ∞ -category $\mathcal{F}(C)$ admits small filtered colimits.*
- (2) *For each edge $e : C \rightarrow C'$ of $\mathcal{C}$, the functor $\mathcal{F}(e) : \mathcal{F}(C) \rightarrow \mathcal{F}(C')$ is finitary.*

Let D be an object of $\mathcal{D}$. If the image of D in each $\mathcal{F}(C)$ is compact, then C is compact.

Proof. Apply Proposition 9.2.9.1 in the special case where $\kappa = \aleph_0$ and $\lambda = \Omega$ is a fixed strongly inaccessible cardinal. $\square$

Warning 9.2.9.3. The converse of Corollary 9.2.9.2 is false in general: that is, the ∞ -category $\mathcal{D}$ might have compact objects which do not have compact image in each $\mathcal{F}(C)$. For example, let $\mathcal{C} = \Delta^1 / \partial\Delta^1$ be the simplicial circle and let $\mathcal{F}$ be the constant functor whose value is (the nerve of) the category of abelian groups. In this case, we can identify $\mathcal{D} = \varprojlim(\mathcal{F})$ with (the nerve of) the category of pairs (M, u) , where M is an abelian group and $u : M \xrightarrow{\sim} M$ is an automorphism of M . In this case, (M, u) is a compact object of $\mathcal{D}$ if and only if M is finitely generated as a module over the Laurent polynomial ring $\mathbf{Z}[u^{\pm 1}]$. This condition does not guarantee that M is finitely generated as an abelian group (compare with Warning 9.2.8.8). 06F8

In the situation of Proposition 9.2.9.1, we can regard $\mathcal{F}$ as the covariant transport representation of a cocartesian fibration $U : \mathcal{E} \rightarrow \mathcal{C}$. In this case, the limit $\varprojlim(\mathcal{F})$ can be identified with the ∞ -category $\mathrm{Fun}_{\mathcal{C}}^{\mathrm{CCart}}(\mathcal{C}, \mathcal{E})$ of cocartesian sections of U (Proposition 7.4.4.1). We will deduce Proposition 9.2.9.1 from a more general result (Proposition 9.2.9.16), which applies to a much larger class of fibrations.

Definition 9.2.9.4. Let $\kappa \leq \lambda$ be regular cardinals and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. We will say that U is (κ, λ) -cocomplete if, for every n -simplex $\sigma : \Delta^n \rightarrow \mathcal{C}$, the fiber product $\mathcal{E}_\sigma = \Delta^n \times_{\mathcal{C}} \mathcal{E}$ is a (κ, λ) -cocomplete ∞ -category (in the sense of Definition 9.2.1.3). 06F9

Variant 9.2.9.5. Let κ be a regular cardinal and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. We say that U is κ -sequentially cocomplete if, for every n -simplex $\sigma : \Delta^n \rightarrow \mathcal{C}$, the fiber product $\mathcal{E}_\sigma = \Delta^n \times_{\mathcal{C}} \mathcal{E}$ is a κ -sequentially cocomplete ∞ -category (Definition 9.2.3.1). In other words, the inner fibration U is κ -sequentially cocomplete if and only if it is (κ, κ^+) -cocomplete (in the sense of Definition 9.2.9.4); see Proposition 9.2.3.6. 06FA

Example 9.2.9.6. Let $\kappa \leq \lambda$ be regular cardinals. Then an ∞ -category $\mathcal{E}$ is (κ, λ) -cocomplete (in the sense of Definition 9.2.1.3) if and only if the projection map $\mathcal{E} \rightarrow \Delta^0$ is a (κ, λ) -cocomplete inner fibration (in the sense of Definition 9.2.9.4). 06FB

Proposition 9.2.9.7. Let $\kappa \leq \lambda$ be regular cardinals and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. The following conditions are equivalent: 06FC

- (1) The inner fibration U is (κ, λ) -cocomplete (in the sense of Definition 9.2.9.4).
- (2) For every edge $\sigma : \Delta^1 \rightarrow \mathcal{C}$, the ∞ -category $\mathcal{E}_\sigma = \Delta^1 \times_{\mathcal{C}} \mathcal{E}$ is (κ, λ) -cocomplete.

- (3) For every vertex $C \in \mathcal{C}$, the ∞ -category $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is (κ, λ) -cocomplete. Moreover, if $\mathcal{K}$ is a λ -small κ -filtered ∞ -category, then every colimit diagram $\mathcal{K}^{\triangleright} \rightarrow \mathcal{E}_C$ is an edgewise U -colimit diagram (see Definition 7.1.7.9).

Proof. The implication (1) $\Rightarrow$ (2) is immediate from the definition. We next show that (2) $\Rightarrow$ (3). Assume that condition (2) is satisfied. For each vertex $C \in \mathcal{C}$, we can apply condition (2) to the degenerate edge id_C to guarantee that the ∞ -category $\Delta^1 \times \mathcal{E}_C$ is (κ, λ) -cocomplete. It follows immediately that the factor $\mathcal{E}_C$ is also (κ, λ) -cocomplete (see Example 7.1.3.11): that is, every λ -small κ -filtered diagram $F : \mathcal{K} \rightarrow \mathcal{E}_C$ can be extended to a colimit diagram $\overline{F} : \mathcal{K}^{\triangleright} \rightarrow \mathcal{E}_C$. We wish to show that in this case, $\overline{F}$ is an edgewise U -colimit diagram. To prove this, we may assume without loss of generality that $\mathcal{C} = \Delta^1$ and that $C \in \mathcal{C}$ is the initial vertex. In this case, condition (2) guarantees that the ∞ -category $\mathcal{E}$ is (κ, λ) -cocomplete, so that f extends to a colimit diagram $\overline{F}' : \mathcal{K}^{\triangleright} \rightarrow \mathcal{E}$. Let us identify $\overline{F}$ and $\overline{F}'$ with objects $X, X' \in \mathcal{E}_{F/}$. Our assumption that $\overline{F}'$ is a colimit diagram guarantees that X' is an initial object of $\mathcal{E}_{F/}$, so that there exists a morphism $X' \rightarrow X$. Then $\overline{F}'$ factors through the full subcategory $\mathcal{E}_C \subseteq \mathcal{E}$, and is therefore also a colimit diagram in $\mathcal{E}_C$. It follows that $\overline{F}$ is isomorphic to $\overline{F}'$ (as an object of the ∞ -category $\text{Fun}(\mathcal{K}^{\triangleright}, \mathcal{E}_C) \subseteq \text{Fun}(\mathcal{K}^{\triangleright}, \mathcal{E})$), and is therefore also a colimit diagram in $\mathcal{E}$.

We now complete the proof by showing that (3) $\Rightarrow$ (1). Assume that condition (3) is satisfied; we wish to show that for every n -simplex $\sigma : \Delta^n \rightarrow \mathcal{C}$, the fiber product $\mathcal{E}_\sigma = \Delta^n \times_{\mathcal{C}} \mathcal{E}$ is (κ, λ) -cocomplete. Replacing $\mathcal{E}$ by $\mathcal{E}_\sigma$, we may assume without loss of generality that $\mathcal{C} = \Delta^n$ is a standard simplex; in this case, we wish to show that the ∞ -category $\mathcal{E}$ is (κ, λ) -cocomplete. Let $\mathcal{K}$ be an ∞ -category which is λ -small and κ -filtered; we must show that every diagram $F : \mathcal{K} \rightarrow \mathcal{E}$ admits a colimit. For $0 \leq i \leq n$, let $\mathcal{K}_i \subseteq \mathcal{K}$ be the full subcategory spanned by those objects K satisfying $(U \circ F)(X) = i$. Since $\mathcal{K}$ is nonempty, there is some largest integer $0 \leq i \leq n$ for which $\mathcal{K}_i$ is nonempty. Applying Corollary 9.1.5.17, we see that $\mathcal{K}_i$ is κ -filtered and the inclusion $\mathcal{K}_i \hookrightarrow \mathcal{K}$ is right cofinal. Using Corollary 7.2.2.10, we can replace F by $F|_{\mathcal{K}_i}$ and thereby reduce to the case where the diagram F takes values in the ∞ -category $\mathcal{E}_i$. In this case, assumption (3) guarantees that F can be extended to a colimit diagram $\overline{F} : \mathcal{K}^{\triangleright} \rightarrow \mathcal{E}_i$ which is also a U -colimit diagram in the ∞ -category $\mathcal{E}$ (Proposition 7.1.7.14). Since $U \circ \overline{F}$ is a colimit diagram in the ∞ -category $\mathcal{C} = \Delta^n$, it follows that $\overline{F}$ is also a colimit diagram in the ∞ -category $\mathcal{E}$ (Corollary 7.1.6.12). $\square$

06FD Remark 9.2.9.8. Let $\kappa \leq \lambda$ be regular cardinals and let $\mathbb{K}$ be the collection of all λ -small κ -filtered ∞ -categories. Proposition 9.2.9.7 asserts that an inner fibration $U : \mathcal{E} \rightarrow \mathcal{C}$ is (κ, λ) -cocomplete (in the sense of Definition 9.2.9.4) if and only if it is $\mathbb{K}$ -cocomplete (in the sense of Definition 7.6.6.19). In particular:

- If U is (κ, λ) -cocomplete, then each fiber $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is a (κ, λ) -cocomplete ∞ -

category (Example 7.6.6.30). The converse holds if U is a locally cartesian fibration, but not in general (Example 7.6.6.29).

- If U is a locally cocartesian fibration, then it is (κ, λ) -cocomplete if and only if each fiber $\mathcal{E}_C$ is a (κ, λ) -cocomplete ∞ -category and the covariant transport functor $e_! : \mathcal{E}_C \rightarrow \mathcal{E}_{C'}$ is (κ, λ) -finitary, for each edge $e : C \rightarrow C'$ of $\mathcal{C}$ (see Example 7.6.6.31).
- If U is an essentially μ -small cocartesian fibration, then it is (κ, λ) -cocomplete if and only if the covariant transport representation $\mathrm{Tr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C} \rightarrow \mathcal{QC}_{<\mu}$ factors through the subcategory $\mathcal{QC}_{<\mu}^{(\kappa, \lambda)\text{-ccomp}}$ of Notation 9.2.2.14 (Example 7.6.6.32).

Remark 9.2.9.9. Let $\kappa \leq \lambda$ be regular cardinals and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an isofibration of ∞ -categories. If the ∞ -category $\mathcal{E}$ is (κ, λ) -cocomplete and the U is a (κ, λ) -finitary functor, then U is (κ, λ) -cocomplete as an inner fibration (Example 7.6.6.35). The converse holds if the ∞ -category $\mathcal{C}$ is (κ, λ) -cocomplete and U is a cocartesian fibration (Proposition 7.6.6.39). 06FE

Example 9.2.9.10. Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. If U is either a left fibration or a right fibration, then it is (κ, λ) -cocomplete for every pair of regular cardinals $\kappa \leq \lambda$. This follows by combining Remark 9.2.9.8 with Example 9.2.1.6 (together with Example 9.2.2.11 in the case of left fibrations). 06FF

Remark 9.2.9.11. Let $\kappa \leq \lambda$ be regular cardinals and suppose we are given a pullback diagram of simplicial sets 06FG

$$\begin{array}{ccc} \mathcal{E}' & \xrightarrow{\quad} & \mathcal{E} \\ \downarrow U' & & \downarrow U \\ \mathcal{C}' & \xrightarrow{\quad} & \mathcal{C} \end{array}$$

If U is a (κ, λ) -cocomplete inner fibration, then U' is also a (κ, λ) -cocomplete inner fibration.

Remark 9.2.9.12. Let $\kappa \leq \lambda$ be regular cardinals and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a (κ, λ) -cocomplete inner fibration of simplicial sets. Then the ∞ -category of sections $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ is (κ, λ) -cocomplete. Moreover, for every object $C \in \mathcal{C}$, the evaluation functor $\mathrm{ev}_C : \mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E}) \rightarrow \mathrm{Fun}_{/\mathcal{C}}(\{C\}, \mathcal{E}) = \mathcal{E}_C$ is (κ, λ) -finitary. By virtue of Remark 9.2.9.8, this is a special case of Corollary 7.1.10.4. 06FH

Remark 9.2.9.13. Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{E}$ be an ∞ -category equipped with a functor $U : \mathcal{E} \rightarrow \Delta^n$. The following conditions are equivalent: 06FJ

- (1) The inner fibration $U : \mathcal{E} \rightarrow \Delta^n$ is (κ, λ) -cocomplete, in the sense of Definition 9.2.9.4.
- (2) For $0 \leq i \leq n$, the fiber $\mathcal{E}_i = U^{-1}\{i\}$ is (κ, λ) -cocomplete, and the inclusion functor $\mathcal{E}_i \hookrightarrow \mathcal{E}$ is (κ, λ) -finitary.

- (3) The ∞ -category $\mathcal{E}$ is (κ, λ) -cocomplete and each of the full subcategories $\mathcal{E}_i \subseteq \mathcal{E}$ is closed under the formation of λ -small κ -filtered colimits.

If these conditions are satisfied, then a functor $F : \mathcal{E} \rightarrow \mathcal{E}'$ is (κ, λ) -finitary if and only if the restriction $F|_{\mathcal{E}_i} : \mathcal{E}_i \rightarrow \mathcal{E}'$ is (κ, λ) -finitary for $0 \leq i \leq n$.

06FK Proposition 9.2.9.14. *Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{E}$ be an ∞ -category equipped with a (κ, λ) -cocomplete inner fibration $U : \mathcal{E} \rightarrow \Delta^1$. Let $f : X \rightarrow Y$ be a morphism in $\mathcal{E}$, where $U(X) = 0$ and $U(Y) = 1$. If X and Y are (κ, λ) -compact objects of $\mathcal{E}$, then f is (κ, λ) -compact when viewed as an object of the ∞ -category $\mathrm{Fun}_{/\Delta^1}(\Delta^1, \mathcal{E})$.*

Proof. The ∞ -category $\mathrm{Fun}_{/\Delta^1}(\Delta^1, \mathcal{E})$ can be identified with the oriented fiber product $\mathcal{E}_0 \tilde{\times}_{\mathcal{E}} \mathcal{E}_1$. The desired result now follows from Proposition 9.2.8.1. $\square$

06FL Warning 9.2.9.15. Let $U : \mathcal{E} \rightarrow \Delta^1$ be as in Proposition 9.2.9.14 and let X be an object of $\mathcal{E}$. If $U(X) = 1$, then X is (κ, λ) -compact when viewed as an object of $\mathcal{E}$ if and only if it is (κ, λ) -compact when viewed as an object of $\mathcal{E}_1$. If $U(X) = 0$, the analogous statement is not necessarily true. In this case, Remark 9.2.9.13 shows that X is (κ, λ) -compact as an object of $\mathcal{E}$ if and only if it is (κ, λ) -compact as an object of $\mathcal{E}_0$ and satisfies the following additional condition:

($\star$) The functor

$$\mathcal{E}_1 \hookrightarrow \mathcal{E} \xrightarrow{\mathrm{Hom}_{\mathcal{E}}(X, \bullet)} \mathcal{S}_{<\mu}$$

is (κ, λ) -finitary. Here $\mu \geq \lambda$ is any infinite cardinal of cofinality $\geq \lambda$ for which $\mathcal{E}$ is locally μ -small (so that the corepresentable functor $\mathrm{Hom}_{\mathcal{E}}(X, \bullet) : \mathcal{E} \rightarrow \mathcal{S}_{<\mu}$ is well-defined).

Note that condition ($\star$) is automatic in either of the following situations:

- The functor U is a cartesian fibration and the contravariant transport functor $\mathcal{E}_1 \rightarrow \mathcal{E}_0$ is (κ, λ) -finitary.
- There exists a U -cocartesian morphism $f : X \rightarrow Y$, where Y is a (κ, λ) -compact object of $\mathcal{E}_1$.

We now prove a generalization of Proposition 9.2.9.14 which applies to inner fibrations over more general bases.

06FM Proposition 9.2.9.16. *Let $\kappa \leq \lambda$ be regular cardinals and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a (κ, λ) -cocomplete inner fibration of simplicial sets. Let $F : \mathcal{C} \rightarrow \mathcal{E}$ be a section of U satisfying the following condition:*

(*) For every edge $e : C \rightarrow C'$ of $\mathcal{C}$, the image $F(C)$ is (κ, λ) -compact when viewed as an object of the ∞ -category $\Delta^1 \times_{\mathcal{C}} \mathcal{E}$.

If the simplicial set $\mathcal{C}$ is κ -small, then F is (κ, λ) -compact when viewed as an object of the ∞ -category $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$.

Warning 9.2.9.17. In the formulation of Proposition 9.2.9.16, we generally cannot replace (*) by the following weaker condition: 06FN

(*)₀ For each vertex $C \in \mathcal{C}$, the image $F(C)$ is (κ, λ) -compact when viewed as an object of the ∞ -category $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$.

However, condition (*)₀ does imply condition (*) under either of the following additional assumptions:

- The inner fibration U is locally cartesian. Moreover, for every edge $e : C \rightarrow C'$ of $\mathcal{C}$, the contravariant transport functor $e^* : \mathcal{E}_{C'} \rightarrow \mathcal{E}_C$ is (κ, λ) -finitary.
- For every edge $e : C \rightarrow C'$ of $\mathcal{C}$, the image $F(C) \rightarrow F(C')$ is a locally U -cocartesian edge of $\mathcal{E}$.

See Warning 9.2.9.15.

Example 9.2.9.18. Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be a (κ, λ) -cocomplete ∞ -category. 06FP For every simplicial set K , we can identify $\mathrm{Fun}(K, \mathcal{C})$ with the ∞ -category of sections of the (κ, λ) -cocomplete inner fibration $K \times \mathcal{C} \rightarrow K$. In this case, Proposition 9.2.9.16 recovers the conclusion of Proposition 9.2.8.7: if K is κ -small, then any diagram of (κ, λ) -compact objects of $\mathcal{C}$ is (κ, λ) -compact when viewed as an object of $\mathrm{Fun}(K, \mathcal{C})$.

Proof of Proposition 9.2.9.16. We proceed as in the proof of Proposition 9.2.8.7. For every morphism of simplicial sets $\mathcal{C}' \rightarrow \mathcal{C}$, Remark 9.2.9.12 guarantees that the ∞ -category $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}', \mathcal{E})$ is (κ, λ) -cocomplete, and that the evaluation functors $\mathrm{ev}_C : \mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}', \mathcal{E}) \rightarrow \mathcal{E}_C$ are (κ, λ) -finitary for each $C \in \mathcal{C}'$. Let us say that $\mathcal{C}'$ is *good* if the restriction $F|_{\mathcal{C}'}$ is (κ, λ) -compact when viewed as an object of the ∞ -category $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}', \mathcal{E})$. We will complete the proof by showing that if $\mathcal{C}'$ is κ -small, then $\mathcal{C}'$ is good.

Note that $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}', \mathcal{E})$ can be realized as the inverse limit of a tower of ∞ -categories

$$\cdots \rightarrow \mathrm{Fun}_{/\mathcal{C}}(\mathrm{sk}_2(\mathcal{C}'), \mathcal{E}) \rightarrow \mathrm{Fun}_{/\mathcal{C}}(\mathrm{sk}_1(\mathcal{C}'), \mathcal{E}) \rightarrow \mathrm{Fun}_{/\mathcal{C}}(\mathrm{sk}_0(\mathcal{C}'), \mathcal{E}),$$

where the transition maps are isofibrations (Corollary 4.4.5.12). Each of the ∞ -categories appearing in this tower is (κ, λ) -cocomplete and each of the transition functors is (κ, λ) -finitary. It will therefore suffice to show that each of the skeleta $\mathrm{sk}_n(\mathcal{C}')$ is good: this is immediate if $\kappa = \aleph_0$ (the assumption that $\mathcal{C}'$ is finite guarantees that it coincides with $\mathrm{sk}_n(\mathcal{C}')$)

for $n \gg 0$), and follows from Corollary 9.2.8.5 when $\kappa > \aleph_0$. We may therefore replace $\mathcal{C}'$ by $\text{sk}_n(\mathcal{C}')$ and thereby reduce to the case where the simplicial set $\mathcal{C}$ has dimension $\leq n$, for some integer $n \geq -1$.

We now proceed by induction on n . If $n = -1$, then the simplicial set $\mathcal{C}'$ is empty and the result is clear. Otherwise, let $\mathcal{C}'' = \text{sk}_{n-1}(\mathcal{C}')$ be the $(n-1)$ -skeleton of $\mathcal{C}'$ and let S be the collection of all nondegenerate n -simplices of $\mathcal{C}$. Applying Proposition 1.1.4.12, we obtain a pullback diagram of ∞ -categories

$$\begin{array}{ccc} \text{Fun}_{/\mathcal{C}}(\mathcal{C}', \mathcal{E}) & \longrightarrow & \text{Fun}_{/\mathcal{C}}(\mathcal{C}'', \mathcal{E}) \\ \downarrow & & \downarrow \\ \prod_{\sigma \in S} \text{Fun}_{/\mathcal{C}}(\Delta^n, \mathcal{E}) & \longrightarrow & \prod_{\sigma \in S} \text{Fun}_{/\mathcal{C}}(\partial \Delta^n, \mathcal{E}). \end{array}$$

Since the horizontal maps in this diagram are isofibrations (Corollary 4.4.5.12), it is also a categorical pullback square (Corollary 4.5.2.28). Moreover, each of the ∞ -categories in the diagram is (κ, λ) -cocomplete of the transition functors is (κ, λ) -finitary. Combining our inductive hypothesis with Corollary 9.2.8.3 and Proposition 9.2.8.4, we can reduce to the case where $\mathcal{C}' = \Delta^n$ is a standard simplex.

If $n = 0$, then the map $\mathcal{C}' \rightarrow \mathcal{C}$ can be identified with a vertex $C \in \mathcal{C}$, and the desired result follows from the observation that $F(C)$ is (κ, λ) -compact when viewed as an object of the ∞ -category $\mathcal{E}_C$ (this is a special case of assumption $(*)$, applied to the degenerate edge $\text{id}_C : C \rightarrow C$). If $n = 1$, then the desired result is a reformulation of Proposition 9.2.9.14. We may therefore assume that $n \geq 2$. Let $\text{Spine}[n] \subseteq \Delta^n$ be as in Example 1.5.7.7. The inclusion $\text{Spine}[n] \hookrightarrow \Delta^n$ is inner anodyne and therefore induces a trivial Kan fibration $\text{Fun}_{/\mathcal{C}}(\Delta^n, \mathcal{E}) \rightarrow \text{Fun}_{/\mathcal{C}}(\text{Spine}[n], \mathcal{E})$. Consequently, to show that Δ^n is good, it will suffice to show that $\text{Spine}[n]$ is good. This follows from our inductive hypothesis, since the simplicial set $\text{Spine}[n]$ has dimension 1. $\square$

06FQ Corollary 9.2.9.19. *Let $\kappa \leq \lambda$ be regular cardinals and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a cocartesian fibration of simplicial sets which is (κ, λ) -cocomplete. Let $\text{Fun}_{/\mathcal{C}}^{\text{CCart}}(\mathcal{C}, \mathcal{E})$ denote the ∞ -category of cocartesian sections of U (Notation 5.3.1.10), and let $F \in \text{Fun}_{/\mathcal{C}}^{\text{CCart}}(\mathcal{C}, \mathcal{E})$ be an object which carries each vertex $C \in \mathcal{C}$ to a (κ, λ) -compact object $F(C) \in \mathcal{E}_C$. If $\mathcal{C}$ is κ -small, then F is (κ, λ) -compact when viewed as an object of $\text{Fun}_{/\mathcal{C}}^{\text{CCart}}(\mathcal{C}, \mathcal{E})$.*

Proof. It follows from Corollary 7.1.10.7 that the ∞ -category $\text{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ admits λ -small κ -filtered colimits, which are preserved by the evaluation functors $\text{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E}) \rightarrow \mathcal{E}_C$ for $C \in \mathcal{C}$. Using Remark 9.2.9.8 we see that the full subcategory $\text{Fun}_{/\mathcal{C}}^{\text{CCart}}(\mathcal{C}, \mathcal{E}) \subseteq \text{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ is closed under the formation of λ -small κ -filtered colimits. Consequently, to show that

F is (κ, λ) -compact as an object of $\mathrm{Fun}_{/\mathcal{C}}^{\mathrm{CCart}}(\mathcal{C}, \mathcal{E})$, it will suffice to show that it is (κ, λ) -compact when viewed as an object of the larger ∞ -category $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$. This follows from Proposition 9.2.9.16 (together with Warning 9.2.9.17). $\square$

Proof of Proposition 9.2.9.1. Let $\kappa \leq \lambda$ and μ be regular cardinals, where μ is uncountable, and let $\mathcal{D}$ be the limit of a κ -small diagram

$$\mathcal{F} : \mathcal{C} \rightarrow \mathcal{QC}_{<\mu}^{(\kappa, \lambda)\text{-ccomp}} \quad (C \in \mathcal{C}) \mapsto \mathcal{F}(C)$$

Then $\mathcal{F}$ is the covariant transport representation of a cocartesian fibration $U : \mathcal{E} \rightarrow \mathcal{C}$ which is essentially μ -small and (κ, λ) -cocomplete (Example 7.6.6.32). Using Proposition 7.4.4.1, we can identify $\mathcal{D}$ with the ∞ -category $\mathrm{Fun}_{/\mathcal{C}}^{\mathrm{CCart}}(\mathcal{C}, \mathcal{E})$ of cocartesian sections of U . Under this identification, each of the projection maps $\mathcal{D} \rightarrow \mathcal{F}(C)$ corresponds to the functor

$$\mathrm{ev}_C : \mathrm{Fun}_{/\mathcal{C}}^{\mathrm{CCart}}(\mathcal{C}, \mathcal{E}) \rightarrow \mathrm{Fun}_{/\mathcal{C}}(\{C\}, \mathcal{E}) = \mathcal{E}_C$$

given by evaluation at C . Applying Corollary 9.2.9.19, we see that if an object $D \in \mathcal{D}$ has (κ, λ) -compact image in each $\mathcal{F}(C)$, then D is (κ, λ) -compact as an object of $\mathcal{D}$. $\square$

9.3 Ind-Completions of ∞ Categories

Let $\mathcal{C}$ be an ∞ -category. In §9.3.1, we show that $\mathcal{C}$ admits an *Ind-completion* $\mathrm{Ind}(\mathcal{C})$, 06FR which is characterized (up to equivalence) by the existence of a functor $H : \mathcal{C} \rightarrow \mathrm{Ind}(\mathcal{C})$ satisfying the following conditions:

- (a) The ∞ -category $\mathrm{Ind}(\mathcal{C})$ admits small filtered colimits.
- (b) For every ∞ -category $\mathcal{D}$ which admits small filtered colimits, precomposition with H induces an equivalence of ∞ -categories

$$\mathrm{Fun}^{\mathrm{fin}}(\mathrm{Ind}(\mathcal{C}), \mathcal{D}) \rightarrow \mathrm{Fun}(\mathcal{C}, \mathcal{D}).$$

Here $\mathrm{Fun}^{\mathrm{fin}}(\mathrm{Ind}(\mathcal{C}), \mathcal{D})$ denotes the full subcategory of $\mathrm{Fun}(\mathrm{Ind}(\mathcal{C}), \mathcal{D})$ spanned by those functors which preserve small filtered colimits (see Definition 9.2.2.1).

Stated more informally, the ∞ -category $\mathrm{Ind}(\mathcal{C})$ is obtained from $\mathcal{C}$ by “freely” adjoining colimits of small filtered diagrams.

It follows immediately from the definitions that if an ∞ -category $\mathcal{C}$ admits an Ind-completion, then $\mathrm{Ind}(\mathcal{C})$ is uniquely determined up to equivalence. The existence of $\mathrm{Ind}(\mathcal{C})$ follows from the general results of §8.4.5. Assume for simplicity that the ∞ -category $\mathcal{C}$ is small. Using Proposition 8.4.5.8, we can identify $\mathrm{Ind}(\mathcal{C})$ with the smallest full subcategory of $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ which contains all representable functors and is closed under small filtered colimits. This subcategory can be described more intrinsically:

- In §9.3.4, we show that a functor $\mathcal{F} : \mathcal{C}^{\text{op}} \rightarrow \mathcal{S}$ belongs to $\text{Ind}(\mathcal{C})$ if and only if the ∞ -category of elements $\int_{\mathcal{C}^{\text{op}}} \mathcal{F}$ is cofiltered (Proposition 9.3.4.5). If this condition is satisfied, we say that the functor $\mathcal{F}$ is *flat* (Definition 9.3.4.1).
- Assume that the ∞ -category $\mathcal{C}$ admits finite colimits (so that $\mathcal{C}^{\text{op}}$ admits finite limits). In §9.3.5, we show that a functor $\mathcal{F} : \mathcal{C}^{\text{op}} \rightarrow \mathcal{S}$ belongs to $\text{Ind}(\mathcal{C})$ if and only if it preserves finite limits (Corollary 9.3.5.27). If this condition is satisfied, we say that $\mathcal{F}$ is *left exact* (see Definition 9.3.5.5 and Theorem 9.3.5.8).

For some applications, it will be useful to have a recognition principle for Ind-completions which does not explicitly reference their universal property. Suppose we are given a functor of ∞ -categories $H : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$, where $\widehat{\mathcal{C}}$ admits small filtered colimits. In §9.3.2, we show that H exhibits $\widehat{\mathcal{C}}$ as an Ind-completion of $\mathcal{C}$ if and only if its essential image consists of compact objects which generate $\widehat{\mathcal{C}}$ under small filtered colimits (Corollary 9.3.2.6). If this condition is satisfied, then $\widehat{\mathcal{C}}$ is generated by $\mathcal{C}$ in a very strong sense: every object of $\widehat{\mathcal{C}}$ can be realized as the colimit of a small filtered diagram which factors through $\mathcal{C}$ (Corollary 9.3.4.16).

063G Remark 9.3.0.1. Let $\mathcal{C}$ be an ∞ -category and let us abuse notation by identifying $\mathcal{C}$ with a full subcategory of its Ind-completion $\text{Ind}(\mathcal{C})$. Then every object $X \in \text{Ind}(\mathcal{C})$ can be realized as the colimit of a small filtered diagram $\{X_i\}_{i \in \mathcal{I}}$ in the ∞ -category $\mathcal{C}$. If $Y \in \text{Ind}(\mathcal{C})$ is the colimit of another small filtered diagram $\{Y_j\}_{j \in \mathcal{J}}$ in $\mathcal{C}$, then we have canonical homotopy equivalences

$$\begin{aligned}
 \text{Hom}_{\text{Ind}(\mathcal{C})}(X, Y) &= \text{Hom}_{\text{Ind}(\mathcal{C})}(\varinjlim_{i \in \mathcal{I}} X_i, Y) \\
 &\simeq \varprojlim_{i \in \mathcal{I}} \text{Hom}_{\text{Ind}(\mathcal{C})}(X_i, Y) \\
 &= \varprojlim_{i \in \mathcal{I}} \text{Hom}_{\text{Ind}(\mathcal{C})}(X_i, \varinjlim_j Y_j) \\
 &\simeq \varprojlim_{i \in \mathcal{I}} \varinjlim_{j \in \mathcal{J}} \text{Hom}_{\text{Ind}(\mathcal{C})}(X_i, Y_j) \\
 &= \varprojlim_{i \in \mathcal{I}} \varinjlim_{j \in \mathcal{J}} \text{Hom}_{\mathcal{C}}(X_i, Y_j).
 \end{aligned}$$

Here the limits and colimits are computed in the ∞ -category of spaces $\mathcal{S}$, and the equivalence on the fourth line comes from the observation that each X_i is compact as an object of $\mathcal{C}$.

We therefore obtain the following more informal description of the ∞ -category $\text{Ind}(\mathcal{C})$:

- Objects of $\text{Ind}(\mathcal{C})$ are represented by small filtered diagrams $\{X_i\}_{i \in \mathcal{I}}$ in the ∞ -category $\mathcal{C}_0$.
- Morphism spaces in $\text{Ind}(\mathcal{C})$ are given by the formula

$$\text{Hom}_{\text{Ind}(\mathcal{C})}(\{X_i\}_{i \in \mathcal{I}}, \{Y_j\}_{j \in \mathcal{J}}) = \varprojlim_{i \in \mathcal{I}} \varinjlim_{j \in \mathcal{J}} \text{Hom}_{\mathcal{C}}(X_i, Y_j).$$

Remark 9.3.0.2. For any ∞ -category $\mathcal{C}$, the Ind-completion $\mathrm{Ind}(\mathcal{C})$ is obtained from $\mathcal{C}$ by (freely) adjoining colimits of diagrams $\mathcal{K} \rightarrow \mathcal{C}$, where $\mathcal{K}$ is a small filtered ∞ -category. One can consider many variants of this construction, where we impose additional conditions on the ∞ -category $\mathcal{K}$. We will be particularly interested in the special case where we demand that $\mathcal{K}$ is κ -filtered and λ -small, for some pair of regular cardinals $\kappa \leq \lambda$; in this case, we denote the corresponding enlargement of $\mathcal{C}$ by $\mathrm{Ind}_\kappa^\lambda(\mathcal{C})$. Most of the pleasant properties of the construction $\mathcal{C} \mapsto \mathrm{Ind}(\mathcal{C})$ hold also for the construction $\mathcal{C} \mapsto \mathrm{Ind}_\kappa^\lambda(\mathcal{C})$, at least when the cardinals κ and λ satisfy the condition $\kappa \trianglelefteq \lambda$ (see Definition 9.1.7.5). In §9.3.6, we show that the formation of restricted Ind-completions is transitive in the following sense:

- For every triple of regular cardinals $\kappa \leq \lambda \leq \mu$, there is a fully faithful functor

$$T : \mathrm{Ind}_\lambda^\mu(\mathrm{Ind}_\kappa^\lambda(\mathcal{C})) \rightarrow \mathrm{Ind}_\kappa^\mu(\mathcal{C});$$

see Construction 9.3.6.2 and Proposition 9.3.6.3.

- If $\kappa \trianglelefteq \lambda \trianglelefteq \mu$, then T is an equivalence of ∞ -categories (Theorem 9.3.6.4).

9.3.1 Ind-Completion

Let $\mathcal{C}$ and $\mathcal{D}$ be ∞ -categories which admit small filtered colimits. Recall that a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is *finitary* if it preserves small filtered colimits (Definition 9.2.2.1), and write $\mathrm{Fun}^{\mathrm{fin}}(\mathcal{C}, \mathcal{D})$ for the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ spanned by the finitary functors from $\mathcal{C}$ to $\mathcal{D}$.

Definition 9.3.1.1. Let $H : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ be a functor of ∞ -categories. We say that H *exhibits* $\widehat{\mathcal{C}}$ as an Ind-completion of $\mathcal{C}$ if the following conditions are satisfied:

- The ∞ -category $\widehat{\mathcal{C}}$ admits small filtered colimits.
- Let $\mathcal{D}$ be any ∞ -category which admits small filtered colimits. Then precomposition with H induces an equivalence of ∞ -categories $\mathrm{Fun}^{\mathrm{fin}}(\widehat{\mathcal{C}}, \mathcal{D}) \rightarrow \mathrm{Fun}(\mathcal{C}, \mathcal{D})$.

Notation 9.3.1.2. Let $\mathcal{C}$ be an ∞ -category. It follows from Proposition 8.4.5.3 that there exists an ∞ -category $\widehat{\mathcal{C}}$ and a functor $H : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ which exhibits $\widehat{\mathcal{C}}$ as an Ind-completion of $\mathcal{C}$. In this case, the ∞ -category $\widehat{\mathcal{C}}$ is uniquely determined up to equivalence and depends functorially on $\mathcal{C}$. To emphasize this dependence, we will often denote $\widehat{\mathcal{C}}$ by $\mathrm{Ind}(\mathcal{C})$ and refer to it as *the* Ind-completion of $\mathcal{C}$. In §9.3.4, we will give a more explicit description of the ∞ -category $\mathrm{Ind}(\mathcal{C})$ in the case where $\mathcal{C}$ is essentially small (Proposition 9.3.4.5).

Variant 9.3.1.3 (Pro-Completions). Let $H : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ be a functor of ∞ -categories. We say that H *exhibits* $\widehat{\mathcal{C}}$ as a Pro-completion of $\mathcal{C}$ if it satisfies the following dual version of Definition 9.3.1.1:

(a') The ∞ -category $\widehat{\mathcal{C}}$ admits small cofiltered limits.

(b') If $\mathcal{D}$ is any ∞ -category which admits small cofiltered limits, then precomposition with H induces an equivalence $\mathrm{Fun}'(\widehat{\mathcal{C}}, \mathcal{D}) \rightarrow \mathrm{Fun}(\mathcal{C}, \mathcal{D})$, where $\mathrm{Fun}'(\widehat{\mathcal{C}}, \mathcal{D})$ is the full subcategory of $\mathrm{Fun}(\widehat{\mathcal{C}}, \mathcal{D})$ spanned by those functors which preserve small cofiltered limits.

If these conditions are satisfied, then the ∞ -category $\widehat{\mathcal{C}}$ is uniquely determined up to equivalence and depends functorially on $\mathcal{C}$. To emphasize this dependence, we will often denote $\widehat{\mathcal{C}}$ by $\mathrm{Pro}(\mathcal{C})$ and refer to it as *the* Pro-completion of $\mathcal{C}$. Note that we have a canonical equivalence $\mathrm{Pro}(\mathcal{C})^{\mathrm{op}} \simeq \mathrm{Ind}(\mathcal{C}^{\mathrm{op}})$.

It will sometimes be useful to work with an infinitary counterpart of Definition 9.3.1.1.

063N **Definition 9.3.1.4.** Let κ be a small regular cardinal. We say that a functor of ∞ -categories $H : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ *exhibits $\widehat{\mathcal{C}}$ as an Ind_{κ} -completion of $\mathcal{C}$* if the following conditions are satisfied:

(a) The ∞ -category $\widehat{\mathcal{C}}$ admits small κ -filtered colimits.

(b) Let $\mathcal{D}$ be any ∞ -category which admits small κ -filtered colimits. Then precomposition with H induces an equivalence of ∞ -categories $\mathrm{Fun}^{\kappa\text{-fin}}(\widehat{\mathcal{C}}, \mathcal{D}) \rightarrow \mathrm{Fun}(\mathcal{C}, \mathcal{D})$.

Here $\mathrm{Fun}^{\kappa\text{-fin}}(\widehat{\mathcal{C}}, \mathcal{D})$ denotes the full subcategory of $\mathrm{Fun}(\widehat{\mathcal{C}}, \mathcal{D})$ spanned by the κ -finitary functors (Definition 9.2.2.3).

063P **Notation 9.3.1.5.** Let $\mathcal{C}$ be an ∞ -category and let κ be a small regular cardinal. It follows from Proposition 8.4.5.3 that there exists an ∞ -category $\widehat{\mathcal{C}}$ and a functor $H : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ which exhibits $\widehat{\mathcal{C}}$ as an Ind_{κ} -completion of $\mathcal{C}$. In this case, the ∞ -category $\widehat{\mathcal{C}}$ is uniquely determined up to equivalence and depends functorially on $\mathcal{C}$. To emphasize this dependence, we will often denote $\widehat{\mathcal{C}}$ by $\mathrm{Ind}_{\kappa}(\mathcal{C})$.

063Q **Example 9.3.1.6.** Let $H : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ be a functor of ∞ -categories. Then H exhibits $\widehat{\mathcal{C}}$ as an Ind -completion of $\mathcal{C}$ (in the sense of Definition 9.3.1.1) if and only if it exhibits $\widehat{\mathcal{C}}$ as an $\mathrm{Ind}_{\aleph_0}$ -completion of $\mathcal{C}$ (in the sense of Definition 9.3.1.4). Stated more informally, we have an equivalence of ∞ -categories $\mathrm{Ind}(\mathcal{C}) \simeq \mathrm{Ind}_{\aleph_0}(\mathcal{C})$.

063R **Variant 9.3.1.7.** Let $\kappa \leq \lambda$ be regular cardinals. We say that a functor of ∞ -categories $H : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ *exhibits $\widehat{\mathcal{C}}$ as an $\mathrm{Ind}_{\kappa}^{\lambda}$ -completion of $\mathcal{C}$* if the following conditions are satisfied:

(a) The ∞ -category $\widehat{\mathcal{C}}$ is (κ, λ) -cocomplete: that is, it admits λ -small κ -filtered colimits (Definition 9.2.1.3).

(b) Let $\mathcal{D}$ be any ∞ -category which is (κ, λ) -cocomplete. Then precomposition with H induces an equivalence of ∞ -categories $\mathrm{Fun}^{(\kappa, \lambda)\text{-fin}}(\widehat{\mathcal{C}}, \mathcal{D}) \rightarrow \mathrm{Fun}(\mathcal{C}, \mathcal{D})$.

Here $\text{Fun}^{(\kappa, \lambda)\text{-fin}}(\widehat{\mathcal{C}}, \mathcal{D})$ denotes the full subcategory of $\text{Fun}(\widehat{\mathcal{C}}, \mathcal{D})$ spanned by the (κ, λ) -finitary functors (Definition 9.2.2.6).

Notation 9.3.1.8. Let $\mathcal{C}$ be an ∞ -category and let $\kappa \leq \lambda$ be regular cardinals. It follows 063S from Proposition 8.4.5.3 that there exists an ∞ -category $\widehat{\mathcal{C}}$ and a functor $H : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ which exhibits $\widehat{\mathcal{C}}$ as an $\text{Ind}_{\kappa}^{\lambda}$ -completion of $\mathcal{C}$. In this case, the ∞ -category $\widehat{\mathcal{C}}$ is uniquely determined up to equivalence and depends functorially on $\mathcal{C}$. To emphasize this dependence, we will often denote $\widehat{\mathcal{C}}$ by $\text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$.

Example 9.3.1.9. Following the convention of Remark 4.7.0.5, a cardinal κ is small if it 063T satisfies $\kappa < \Omega$, where Ω is some fixed strongly inaccessible cardinal. In this case, a functor of ∞ -categories $H : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ exhibits $\widehat{\mathcal{C}}$ as an Ind_{κ} -completion of $\mathcal{C}$ (in the sense of Definition 9.3.1.4) if and only if it exhibits $\widehat{\mathcal{C}}$ as an $\text{Ind}_{\kappa}^{\Omega}$ -completion of $\mathcal{C}$ (in the sense of Variant 9.3.1.7). In particular, H exhibits $\widehat{\mathcal{C}}$ as an Ind -completion of $\mathcal{C}$ if and only if it exhibits $\widehat{\mathcal{C}}$ as an $\text{Ind}_{\aleph_0}^{\Omega}$ -completion of $\mathcal{C}$. Stated more informally, we have equivalences

$$\text{Ind}_{\kappa}(\mathcal{C}) \simeq \text{Ind}_{\kappa}^{\Omega}(\mathcal{C}) \quad \text{Ind}(\mathcal{C}) \simeq \text{Ind}_{\aleph_0}^{\Omega}(\mathcal{C}).$$

Example 9.3.1.10 (Idempotent-Completion). Let κ be a regular cardinal and let $H : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ 063U be a functor of ∞ -categories. Then:

- If κ is uncountable, then H exhibits $\widehat{\mathcal{C}}$ as an $\text{Ind}_{\kappa}^{\kappa}$ -completion of $\mathcal{C}$ if and only if it exhibits $\widehat{\mathcal{C}}$ as an idempotent-completion of $\mathcal{C}$.
- If $\kappa = \aleph_0$, then H exhibits $\widehat{\mathcal{C}}$ as an $\text{Ind}_{\aleph_0}^{\aleph_0}$ -completion of $\mathcal{C}$ if and only if it is an equivalence of ∞ -categories.

See Proposition 9.2.1.14.

Remark 9.3.1.11. Let $\kappa \leq \lambda$ be regular cardinals and let $H : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ be a functor 06FS which exhibits $\widehat{\mathcal{C}}$ as an $\text{Ind}_{\kappa}^{\lambda}$ -completion of $\mathcal{C}$. Then H is a weak homotopy equivalence: that is, for every Kan complex X , composition with H induces a homotopy equivalence $\text{Fun}(\widehat{\mathcal{C}}, X) \rightarrow \text{Fun}(\mathcal{C}, X)$. This is a special case of the universal property appearing in Variant 9.3.1.7, since the Kan X is (κ, λ) -cocomplete when viewed as an ∞ -category (Example 9.2.1.6), and every functor $\widehat{\mathcal{C}} \rightarrow X$ is (κ, λ) -finitary (Example 9.2.2.11).

Definition 9.3.1.12 (Ind-Extensions of Functors). Let $\mathcal{C}$ be an ∞ -category. Fix regular 063X cardinals $\kappa \leq \lambda$ and a functor $H : \mathcal{C} \rightarrow \text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ which exhibits $\text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ as an $\text{Ind}_{\kappa}^{\lambda}$ -completion of $\mathcal{C}$. Suppose we are given a functor of ∞ -categories $f : \mathcal{C} \rightarrow \mathcal{D}$, where $\mathcal{D}$ is (κ, λ) -cocomplete. Then there is a (κ, λ) -finitary functor $F : \text{Ind}_{\kappa}^{\lambda}(\mathcal{C}) \rightarrow \mathcal{D}$ and an isomorphism of functors $\alpha : f \rightarrow F \circ H$. Moreover, the pair (F, α) is unique up to (canonical) isomorphism. In this case, we say that α exhibits F as an $\text{Ind}_{\kappa}^{\lambda}$ -extension of f . In the special case $\kappa < \lambda = \Omega$, we also say that α exhibits F as an Ind_{κ} -extension of f . If $\kappa = \aleph_0$ and $\lambda = \Omega$, we say that α exhibits F as an Ind -extension of f .

063Y **Remark 9.3.1.13** (Ind-Extensions as Kan Extensions). In the situation of Definition 9.3.1.12, suppose that we are given functors $f : \mathcal{C} \rightarrow \mathcal{D}$ and $F : \mathrm{Ind}_\kappa^\lambda(\mathcal{C}) \rightarrow \mathcal{D}$ and a natural transformation $\alpha : f \rightarrow F \circ H$. The following conditions are equivalent:

- (1) The natural transformation α exhibits F as an $\mathrm{Ind}_\kappa^\lambda$ -extension of f , in the sense of Definition 9.3.1.12. That is, the functor F is (κ, λ) -finitary and α is an isomorphism.
- (2) The natural transformation α exhibits F as a left Kan extension of f along H , in the sense of Variant 7.3.1.5.

See Corollary 8.4.5.11.

063Z **Remark 9.3.1.14.** Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category. The following conditions are equivalent:

- (1) The ∞ -category $\mathcal{C}$ is (κ, λ) -cocomplete: that is, it admits λ -small κ -filtered colimits.
- (2) The tautological map $H : \mathcal{C} \rightarrow \mathrm{Ind}_\kappa^\lambda(\mathcal{C})$ admits a left adjoint $F : \mathrm{Ind}_\kappa^\lambda(\mathcal{C}) \rightarrow \mathcal{C}$.

Moreover, if these conditions are satisfied, then the functor F is a $\mathrm{Ind}_\kappa^\lambda$ -extension of the identity functor $\mathrm{id}_\mathcal{C}$ (more precisely, if $\alpha : \mathrm{id}_\mathcal{C} \rightarrow H \circ F$ is the unit of an adjunction, then α exhibits F as an $\mathrm{Ind}_\kappa^\lambda$ -extension of $\mathrm{id}_\mathcal{C}$). See Proposition 8.4.5.13.

9.3.2 Recognition of Ind-Completions

0650 We now use the theory of compact objects developed in §9.2.5 to formulate a recognition principle for Ind-completions. Our starting point is the following special case of Lemma 8.4.7.8:

0651 **Proposition 9.3.2.1.** *Let $\kappa \leq \lambda$ be regular cardinals and let $f : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories satisfying the following conditions:*

- (0) *The ∞ -category $\mathcal{D}$ admits λ -small κ -filtered colimits.*
- (1) *The functor f is fully faithful.*
- (2) *For each object $C \in \mathcal{C}$, the image $f(C)$ is a (κ, λ) -compact object of $\mathcal{D}$.*

Then the $\mathrm{Ind}_\kappa^\lambda$ -extension of f is a fully faithful functor $F : \mathrm{Ind}_\kappa^\lambda(\mathcal{C}) \rightarrow \mathcal{D}$.

0652 **Corollary 9.3.2.2.** *Let $\kappa \leq \lambda$ be regular cardinals and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. If F is fully faithful, then the functor $\mathrm{Ind}_\kappa^\lambda(F) : \mathrm{Ind}_\kappa^\lambda(\mathcal{C}) \rightarrow \mathrm{Ind}_\kappa^\lambda(\mathcal{D})$ is fully faithful.*

Proof. Combine Proposition 9.3.2.1 with Remark 9.3.3.9. □

Applying Variant 8.4.7.9, we obtain the following recognition principle for Ind-completions:

Proposition 9.3.2.3. *Let $\kappa \leq \lambda$ be regular cardinals and let $f : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Then f exhibits $\mathcal{D}$ as an $\text{Ind}_\kappa^\lambda$ -completion of $\mathcal{C}$ if and only if it satisfies conditions (0), (1), and (2) of Proposition 9.3.2.1, together with the following additional condition:*

- (3) *The ∞ -category $\mathcal{D}$ is generated under λ -small κ -filtered colimits by the image of f . That is, if $\mathcal{D}_0 \subseteq \mathcal{D}$ is a full subcategory which contains $f(\mathcal{C})$ and is closed under λ -small κ -filtered colimits, then $\mathcal{D}_0 = \mathcal{D}$.*

Remark 9.3.2.4. We will see later that, if the functor f exhibits $\mathcal{D}$ as an $\text{Ind}_\kappa^\lambda$ -completion of $\mathcal{C}$, then it satisfies the following stronger version of condition (3):

- (3⁺) Every object $\mathcal{D}$ can be realized as the colimit of a diagram

$$\mathcal{K} \rightarrow \mathcal{C} \xrightarrow{f} \mathcal{D},$$

where $\mathcal{K}$ is a λ -small κ -filtered ∞ -category.

In other words, every object of $\text{Ind}_\kappa^\lambda(\mathcal{C})$ can be built in a single step as a λ -small κ -filtered colimit of objects of $\mathcal{C}$ (rather than iteratively). See Corollary 9.3.4.16.

Corollary 9.3.2.5. *Let κ be a small regular cardinal and $f : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Then f exhibits $\mathcal{D}$ as an Ind_κ -completion of $\mathcal{C}$ if and only if the following conditions are satisfied:*

- (0) *The ∞ -category $\mathcal{D}$ admits small κ -filtered colimits.*
- (1) *The functor f is fully faithful.*
- (2) *For each object $X \in \mathcal{C}$, the image $f(X)$ is a κ -compact object of $\mathcal{D}$.*
- (3) *The ∞ -category $\mathcal{D}$ is generated under small κ -filtered colimits by the image of f .*

Moreover, if f is assumed only to satisfy conditions (0), (1), and (2), then its Ind_κ -extension $F : \text{Ind}_\kappa(\mathcal{C}) \rightarrow \mathcal{D}$ is fully faithful.

Corollary 9.3.2.6. *Let $f : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Then f exhibits $\mathcal{D}$ as an Ind -completion of $\mathcal{C}$ if and only if the following conditions are satisfied:*

- (0) *The ∞ -category $\mathcal{D}$ admits small filtered colimits.*
- (1) *The functor f is fully faithful.*

(2) For each object $X \in \mathcal{C}$, the image $f(X)$ is a compact object of $\mathcal{D}$.

(3) The ∞ -category $\mathcal{D}$ is generated under small filtered colimits by the image of f .

Moreover, if f satisfies conditions (0), (1), and (2), then its Ind-extension $F : \text{Ind}(\mathcal{C}) \rightarrow \mathcal{D}$ is fully faithful.

0657 **Example 9.3.2.7.** Let Set be the category of sets, and let Set_{fin} be the full subcategory spanned by the finite sets. Then the inclusion functor $\text{Set}_{\text{fin}} \hookrightarrow \text{Set}$ exhibits (the nerve of) Set as an Ind-completion of the Set_{fin} . This follows from Corollary 9.3.2.6, since every finite set is a compact object of Set (Example 9.2.0.4) and every set can be realized as a filtered colimit of finite sets.

0658 **Example 9.3.2.8.** Let R be an associative ring, let $\mathcal{C}$ be (the nerve of) the category of left R -modules, and let $\mathcal{C}_{\text{fin}}$ denote the full subcategory of $\mathcal{C}$ spanned by the finitely presented left R -modules. Then the inclusion functor $\mathcal{C}_{\text{fin}} \hookrightarrow \mathcal{C}$ exhibit $\mathcal{C}$ as an Ind-completion of $\mathcal{C}_{\text{fin}}$. This follows from Corollary 9.3.2.6, since every finitely presented R -module M is a compact object of $\mathcal{C}$ (Proposition 9.2.0.1), and every R -module can be realized as a filtered colimit of finitely presented R -modules. This assertion has counterparts for many other mathematical structures studied in algebra; see Remark 9.2.0.3.

0659 **Variant 9.3.2.9** (Lazard's Theorem). Let R be an associative ring. Recall that a (left) R -module M is *flat* if the tensor product functor

$$\{\text{Right } R\text{-modules}\} \xrightarrow{\otimes_R M} \{\text{Abelian Groups}\}$$

is exact. It is easy to see that the collection of flat R -modules is closed under the formation of filtered colimits. Conversely, a theorem of Lazard ([41]) asserts that every flat R -module M can be realized as a filtered colimit of free R -modules of finite rank (see [?] for a more general statement). It follows that the category of flat R -modules is an Ind-completion of the full subcategory spanned by the free R -modules of finite rank.

065A **Example 9.3.2.10.** Let X be a Kan complex. Then the identity map $\text{id}_X : X \rightarrow X$ exhibits X as an Ind-completion of itself. This follows from the criterion of Corollary 9.3.2.6, since every vertex $x \in X$ is compact (see Example 9.2.5.5). More generally, for every pair of regular cardinals $\kappa \leq \lambda$, the identity map id_X exhibits X as an $\text{Ind}_{\kappa}^{\lambda}$ -completion of itself.

065B **Example 9.3.2.11.** Let S be a set. For every regular cardinal κ , let $\text{Sub}_{<\kappa}(S)$ denote the nerve of the partially ordered set of κ -small subsets of S . For every regular cardinal $\lambda \geq \kappa$, Proposition 9.3.2.1 and Variant 9.2.5.11 supplies a fully faithful functor

$$\text{Ind}_{\kappa}^{\lambda}(\text{Sub}_{<\kappa}(S)) \hookrightarrow \text{Sub}_{<\lambda}(S).$$

This functor is an equivalence if and only if every λ -small subset $S' \subseteq S$ can be realized as a λ -small κ -filtered union of κ -small subsets of S' (Remark 9.3.2.4). Assuming that S has cardinality $\geq \lambda$, this is equivalent to the requirement that $\kappa \leq \lambda$ (see Definition 9.1.7.5).

Exercise 9.3.2.12 (Ind-Completion of Partially Ordered Sets). Let $(A, \leq)$ be a (small) 065C partially ordered set. Recall that an *ideal* of A is a subset $J \subseteq A$ satisfying the following conditions:

- The set J is downward-closed: that is, for elements $a \leq b$ of A , if b belongs to J , then a also belongs to J .
- The set J is directed: that is, every finite subset of J has an upper bound (which is also contained in J).

Let $\widehat{A}$ denote the collection of all ideals $J \subseteq A$, which we regard as partially ordered by inclusion. Show that the nondecreasing function

$$A \rightarrow \widehat{A} \quad (b \in A) \mapsto (A_{\leq b} = \{a \in A : a \leq b\})$$

exhibits the ∞ -category $N_{\bullet}(\widehat{A})$ as an Ind-completion of $N_{\bullet}(A)$.

It follows from Exercise 9.3.2.12 that if an ∞ -category $\mathcal{C}$ is equivalent to the nerve of a partially ordered set, then the Ind-completion $\text{Ind}(\mathcal{C})$ has the same property. This is a special case of the following more generally assertion:

Proposition 9.3.2.13. *Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category, and let n be 065D an integer. Then $\mathcal{C}$ is locally n -truncated (see Definition 4.8.2.1) if and only if $\text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ is locally n -truncated.*

Proof. Choose a functor $H : \mathcal{C} \rightarrow \text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ which exhibits $\text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ as an $\text{Ind}_{\kappa}^{\lambda}$ -completion of $\mathcal{C}$. Assume that $\mathcal{C}$ is locally n -truncated; we will show that $\text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ has the same property (the converse is immediate, since the functor H is fully faithful). Fix objects $\widehat{X}, \widehat{Y} \in \text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$; we wish to show that the morphism space $\text{Hom}_{\text{Ind}_{\kappa}^{\lambda}(\mathcal{C})}(\widehat{X}, \widehat{Y})$ is an n -truncated Kan complex. Let us first regard the object $\widehat{Y}$ as fixed, and let $\mathcal{D}$ denote the full subcategory of $\text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ spanned by those objects $\widehat{X}$ for which $\text{Hom}_{\text{Ind}_{\kappa}^{\lambda}(\mathcal{C})}(\widehat{X}, \widehat{Y})$ is n -truncated. Since the collection of n -truncated spaces is closed under limits (Remark 7.4.1.5), we see that $\mathcal{D}$ is closed under colimits in $\text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ (see Proposition 7.4.1.18). In particular, it is closed under λ -small κ -filtered colimits. Consequently, to show that $\mathcal{D} = \text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$, it will suffice to show that the mapping space $\text{Hom}_{\text{Ind}(\mathcal{C})}(\widehat{X}, \widehat{Y})$ is n -truncated in the special case $\widehat{X} = H(X)$ for some object $X \in \mathcal{C}$.

Let us now regard the object $\widehat{X} = H(X)$ as fixed, and let $\mathcal{D}' \subseteq \text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ denote the full subcategory spanned by those objects $\widehat{Y}$ for which the morphism space $\text{Hom}_{\text{Ind}_{\kappa}^{\lambda}(\mathcal{C})}(\widehat{X}, \widehat{Y})$ is

an n -truncated Kan complex. Since $\widehat{X}$ is a (κ, λ) -compact object of $\mathrm{Ind}_\kappa^\lambda(\mathcal{C})$, the subcategory $\mathcal{D}'$ is closed under λ -small κ -filtered colimits (Variant 9.1.9.3). Consequently, to prove that $\mathcal{D}' = \mathrm{Ind}_\kappa^\lambda(\mathcal{C})$, it will suffice to show that it contains $H(Y)$, for each object $Y \in \mathcal{C}$. Since H is fully faithful, we are reduced to proving that the morphism space $\mathrm{Hom}_{\mathcal{C}}(X, Y)$ is n -truncated, which follows from our assumption that the ∞ -category $\mathcal{C}$ is locally n -truncated. $\square$

065E Corollary 9.3.2.14. *Let $\mathcal{C}$ be an ∞ -category. If $\mathcal{C}$ is equivalent to the nerve of an ordinary category, then $\mathrm{Ind}(\mathcal{C})$ has the same property.*

Proof. Apply Proposition 9.3.2.13 in the special case where $\kappa = \aleph_0$, $\lambda = \Omega$ (Example 9.3.1.9) and $n = 0$ (see Corollary 4.8.2.16). $\square$

065F Remark 9.3.2.15 (Ind-Completions of Ordinary Categories). Let $\mathcal{C}$ be an ordinary category. It follows from Corollary 9.3.2.14 that there is a functor $H : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ for which the induced map $N_\bullet(H) : N_\bullet(\mathcal{C}) \rightarrow N_\bullet(\widehat{\mathcal{C}})$ exhibits $N_\bullet(\widehat{\mathcal{C}})$ as an Ind-completion of the ∞ -category $N_\bullet(\mathcal{C})$. We then have the following:

(a) The category $\widehat{\mathcal{C}}$ admits small filtered colimits.

(b) For every category $\mathcal{D}$ which admits small filtered colimits, composition with H induces an equivalence

$$\mathrm{Fun}^{\mathrm{fin}}(\widehat{\mathcal{C}}, \mathcal{D}) \rightarrow \mathrm{Fun}(\mathcal{C}, \mathcal{D}),$$

where $\mathrm{Fun}^{\mathrm{fin}}(\widehat{\mathcal{C}}, \mathcal{D})$ is the full subcategory of $\mathrm{Fun}(\widehat{\mathcal{C}}, \mathcal{D})$ spanned by those functors which preserve small filtered colimits.

These properties determine the category $\widehat{\mathcal{C}}$ uniquely up to equivalence. To emphasize the uniqueness, we denote $\widehat{\mathcal{C}}$ by $\mathrm{Ind}(\mathcal{C})$ and refer to it as the Ind-completion of the category $\mathcal{C}$. Corollary 9.3.2.14 then supplies an equivalence of ∞ -categories

$$\mathrm{Ind}(N_\bullet(\mathcal{C})) \xrightarrow{\sim} N_\bullet(\mathrm{Ind}(\mathcal{C})).$$

In other words, the category $\mathrm{Ind}(\mathcal{C})$ automatically satisfies a stronger version of condition (b), where we allow $\mathcal{D}$ to be an ∞ -category.

065G Proposition 9.3.2.16. *Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category. Then the tautological functor $F : \mathcal{C} \rightarrow \mathrm{Ind}_\kappa^\lambda(\mathcal{C})$ preserves all κ -small colimits which exist in $\mathcal{C}$.*

Proof. Let $\mu \geq \lambda$ be an uncountable cardinal of exponential cofinality $\geq \kappa$ such that $\mathrm{Ind}_\kappa^\lambda(\mathcal{C})$ is locally μ -small, and let $h^\bullet : \mathrm{Ind}_\kappa^\lambda(\mathcal{C})^{\mathrm{op}} \rightarrow \mathrm{Fun}(\mathrm{Ind}_\kappa^\lambda(\mathcal{C}), \mathcal{S}_{<\mu})$ be a contravariant Yoneda embedding for $\mathrm{Ind}_\kappa^\lambda(\mathcal{C})$. By virtue of Proposition 7.4.1.18, it will suffice to show that the composite functor $(h^\bullet \circ F^{\mathrm{op}}) : \mathcal{C}^{\mathrm{op}} \rightarrow \mathrm{Fun}(\mathrm{Ind}_\kappa^\lambda(\mathcal{C}), \mathcal{S}_{<\mu})$ preserves all κ -small limits which exist in $\mathcal{C}$.

Since F carries each object of $\mathcal{C}$ to a (κ, λ) -compact object of $\mathrm{Ind}_\kappa^\lambda(\mathcal{C})$ (Proposition 9.3.2.3), the functor $h^\bullet \circ F^{\mathrm{op}}$ factors through the full subcategory $\mathrm{Fun}^{(\kappa, \lambda)-\mathrm{fin}}(\mathrm{Ind}_\kappa^\lambda(\mathcal{C}), \mathcal{S}_{<\mu})$ of (κ, λ) -finitary functors from $\mathrm{Ind}(\mathcal{C})$ to $\mathcal{S}_{<\mu}$. Since λ -small κ -filtered colimits commute with κ -small limits in $\mathcal{S}_{<\mu}$ (Proposition 9.1.5.10), the subcategory $\mathrm{Fun}^{(\kappa, \lambda)-\mathrm{fin}}(\mathrm{Ind}_\kappa^\lambda(\mathcal{C}), \mathcal{S}_{<\mu})$ is closed under κ -small limits. It will therefore suffice to show that $(h^\bullet \circ F^{\mathrm{op}}) : \mathcal{C}^{\mathrm{op}} \rightarrow \mathrm{Fun}^{(\kappa, \lambda)-\mathrm{fin}}(\mathrm{Ind}_\kappa^\lambda(\mathcal{C}), \mathcal{S}_{<\mu})$ preserves finite limits. Since F exhibits $\mathrm{Ind}_\kappa^\lambda(\mathcal{C})$ as an $\mathrm{Ind}_\kappa^\lambda$ -completion of $\mathcal{C}$, precomposition with F induces an equivalence of ∞ -categories $F^* : \mathrm{Fun}^{(\kappa, \lambda)-\mathrm{fin}}(\mathrm{Ind}_\kappa^\lambda(\mathcal{C}), \mathcal{S}_{<\mu}) \rightarrow \mathrm{Fun}(\mathcal{C}, \mathcal{S}_{<\mu})$. We are therefore reduced to showing that the composite functor

$$(F^* \circ h^\bullet \circ F^{\mathrm{op}}) : \mathcal{C}^{\mathrm{op}} \rightarrow \mathrm{Fun}(\mathcal{C}, \mathcal{S}_{<\mu})$$

preserves κ -small limits. Since F is fully faithful, this composition is a contravariant Yoneda embedding for the ∞ -category $\mathcal{C}$, and therefore preserves all limits which exist in $\mathcal{C}^{\mathrm{op}}$ (Proposition 7.4.1.18). $\square$

We now record some important special cases of Proposition 9.3.2.3.

Proposition 9.3.2.17. *Let $\mathcal{S}$ denote the ∞ -category of spaces, and let $\mathcal{S}_{\mathrm{fin}}$ be the full subcategory spanned by the essentially finite Kan complexes (Definition 9.2.6.1). Then the inclusion functor $\iota : \mathcal{S}_{\mathrm{fin}} \hookrightarrow \mathcal{S}$ exhibits $\mathcal{S}$ as an Ind-completion of $\mathcal{S}_{\mathrm{fin}}$.* 06FT

Proof. The ∞ -category $\mathcal{S}$ admits small filtered colimits (Corollary 7.4.3.10), and every object of $\mathcal{S}_{\mathrm{fin}}$ is compact when viewed as an object of $\mathcal{S}$ (Corollary 9.2.6.5). Recall that every (small) simplicial set X can be realized as the colimit of a (small) filtered diagram $\{X_\alpha\}$, where each X_α is a finite simplicial set (Remark 3.6.1.8). Applying Proposition 3.3.6.4, we conclude that $\mathrm{Ex}^\infty(X)$ can be realized as the colimit of a (small) filtered diagram $\{\mathrm{Ex}^\infty(X_\alpha)\}$ in the category of simplicial sets, and therefore also in the ∞ -category $\mathcal{S}$ (Variant 9.1.6.4). If X is a Kan complex, then it is homotopy equivalent to $\mathrm{Ex}^\infty(X)$ (Proposition 3.3.6.7), and can therefore be realized as the colimit of a small filtered diagram of essentially finite Kan complexes. The desired result now follows from the criterion of Corollary 9.3.2.6. $\square$

Variant 9.3.2.18. Let $\kappa \leq \lambda$ be uncountable regular cardinals. Then the inclusion functor $\mathcal{S}_{<\kappa} \hookrightarrow \mathcal{S}_{<\lambda}$ induces a fully faithful functor $\mathrm{Ind}_\kappa^\lambda(\mathcal{S}_{<\kappa}) \rightarrow \mathcal{S}_{<\lambda}$. If $\kappa \trianglelefteq \lambda$, then this functor is an equivalence of ∞ -categories: that is, the inclusion exhibits $\mathcal{S}_{<\lambda}$ as an $\mathrm{Ind}_\kappa^\lambda$ -completion of $\mathcal{S}_{<\kappa}$. 06FU

Proof. We assume that λ is uncountable (otherwise, $\kappa = \lambda$ and there is nothing to prove). Note that $\mathcal{S}_{<\lambda}$ admits λ -small colimits (Corollary 7.4.3.10), and that objects of $\mathcal{S}_{<\kappa}$ are (κ, λ) -compact when viewed as objects of $\mathcal{S}_{<\lambda}$ (for κ uncountable, this is Proposition 9.2.6.10). The first assertion now follows from Proposition 9.3.2.1. To prove the second, assume that $\kappa \trianglelefteq \lambda$. Then every λ -small simplicial set X can be realized as the colimit of a

λ -small κ -filtered diagram $\{X_\alpha\}$, where each X_α is κ -small (see Lemma 9.1.7.18). Applying Proposition 3.3.6.4, we conclude that $\mathrm{Ex}^\infty(X)$ can be realized as the colimit of a (small) filtered diagram $\{\mathrm{Ex}^\infty(X_\alpha)\}$ in the category of simplicial sets, and therefore also in the ∞ -category $\mathcal{S}_{<\lambda}$ (Variant 9.1.6.4). If X is a Kan complex, then it is homotopy equivalent to $\mathrm{Ex}^\infty(X)$ (Proposition 3.3.6.7), and can therefore be realized the colimit of a λ -small κ -filtered diagram in $\mathcal{S}_{<\kappa}$. The desired result now follows from the criterion of Proposition 9.3.2.3. $\square$

0684 **Corollary 9.3.2.19.** *Let κ be a small uncountable regular cardinal. Then the inclusion functor $\mathcal{S}_{<\kappa} \hookrightarrow \mathcal{S}$ exhibits $\mathcal{S}$ as an Ind_κ -completion of $\mathcal{S}_{<\kappa}$.*

Proof. Apply Variant 9.3.2.18 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal (here the inequality $\kappa < \lambda$ guarantees that $\kappa \triangleleft \lambda$; see Example 9.1.7.11). $\square$

068R **Remark 9.3.2.20.** The conclusion of Corollary 9.3.2.19 is also valid in the case $\kappa = \aleph_0$, provided that we follow the convention that $\mathcal{S}_{<\aleph_0}$ denotes the full subcategory of $\mathcal{S}$ spanned by its compact objects: that is, the full subcategory spanned by the finitely dominated Kan complexes (Proposition 9.2.6.7). Note that this is a slightly different assertion than Proposition 9.3.2.17, because the inclusion $\mathcal{S}_{\mathrm{fin}} \hookrightarrow \mathcal{S}_{<\aleph_0}$ is not an equivalence of ∞ -categories. This is a special case of a more general phenomenon: a Morita equivalence of ∞ -categories induces an equivalence between their Ind -completions. See Exercise 9.4.1.20.

The preceding results have counterparts for the ∞ -category $\mathcal{QC}$ of small ∞ -categories.

06FV **Proposition 9.3.2.21.** *Let $\mathcal{QC}$ denote the ∞ -category of (small) ∞ -categories and let $\mathcal{QC}_{\mathrm{fin}} \subset \mathcal{QC}$ be the full subcategory spanned by the essentially finite ∞ -categories (Definition 9.2.7.1). Then the inclusion functor $\iota : \mathcal{QC}_{\mathrm{fin}} \hookrightarrow \mathcal{QC}$ exhibits $\mathcal{QC}$ as an Ind -completion of the full subcategory $\mathcal{QC}_{\mathrm{fin}}$ of essentially finite ∞ -categories.*

Proof. The ∞ -category $\mathcal{QC}$ admits small filtered colimits (Corollary 7.4.5.3), and every object of $\mathcal{QC}_{\mathrm{fin}}$ is compact when viewed as an object of $\mathcal{QC}$ (Proposition 9.2.7.9). By virtue of Corollary 9.3.2.6, it will suffice to show that every small ∞ -category $\mathcal{C}$ can be realized as the colimit of a small filtered diagram $\{\mathcal{C}_\alpha\}$ in the ∞ -category $\mathcal{QC}$, where each $\mathcal{C}_\alpha$ is essentially finite. Let $Q : \mathrm{Set}_\Delta \rightarrow \mathrm{Set}_\Delta$ be a finitary functor which associates to each simplicial set K an ∞ -category $Q(K)$ equipped with a categorical equivalence $u_K : K \rightarrow Q(K)$ (Proposition 4.1.3.2). Without loss of generality, we may assume that $\mathcal{C} = Q(K)$ for some small simplicial set K . In this case, we can take $\{\mathcal{C}_\alpha\}$ to be the diagram $\{Q(K_\alpha)\}$, where K_α ranges over the collection of all finite simplicial subsets of K (see Remark 3.6.1.8). $\square$

06FW **Variant 9.3.2.22.** Let $\kappa \leq \lambda$ be uncountable regular cardinals. Then the inclusion $\iota : \mathcal{QC}_{<\kappa} \hookrightarrow \mathcal{QC}_{<\lambda}$ induces a fully faithful functor $\mathrm{Ind}_\kappa^\lambda(\mathcal{QC}_{<\kappa}) \rightarrow \mathcal{QC}_{<\lambda}$. If $\kappa \leq \lambda$, then this functor is an equivalence: that is, ι exhibits $\mathcal{QC}_{<\lambda}$ as an $\mathrm{Ind}_\kappa^\lambda$ -completion of $\mathcal{QC}_{<\kappa}$.

Proof. Note that $\mathcal{QC}_{<\lambda}$ admits λ -small colimits (Corollary 7.4.5.22), and that objects of $\mathcal{QC}_{<\kappa}$ are (κ, λ) -compact when viewed as objects of $\mathcal{QC}_{<\lambda}$ (Proposition 9.2.7.15). The first assertion now follows from Proposition 9.3.2.1. To prove the second, it will suffice to show that every λ -small ∞ -category $\mathcal{C}$ can be realized as the colimit of a λ -small κ -filtered diagram in $\mathcal{QC}_{<\kappa}$. This follows from Variant 9.1.7.21 and Corollary 9.1.6.3. $\square$

Corollary 9.3.2.23. *Let κ be a small uncountable regular cardinal. Then the inclusion 068T*
functor $\mathcal{QC}_{<\kappa} \hookrightarrow \mathcal{QC}$ exhibits $\mathcal{QC}$ as an Ind_κ -completion of $\mathcal{QC}_{<\kappa}$.

Proof. Apply Variant 9.3.2.22 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal. $\square$

9.3.3 Functoriality of Ind-Completion

In §9.3.1, we observed that every ∞ -category $\mathcal{C}$ admits an Ind-completion $\text{Ind}(\mathcal{C})$, which 06FX
 is well-defined up to equivalence (Notation 9.3.1.2). In this section, we show that the construction $\mathcal{C} \mapsto \text{Ind}(\mathcal{C})$ can be upgraded to a functor of ∞ -categories. To formulate this result precisely, we will need to take some care about the sizes of the ∞ -categories under consideration.

Proposition 9.3.3.1. *Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category. Suppose 06FY*
that $\mathcal{C}$ is locally μ -small, where $\mu \geq \lambda$ is a regular cardinal of exponential cofinality $\geq \lambda$.
Then $\text{Ind}_\kappa^\lambda(\mathcal{C})$ is also locally μ -small.

Proof. This is a special case of Proposition 8.4.6.10. $\square$

Corollary 9.3.3.2. *Let $\mathcal{C}$ be a locally small ∞ -category. Then the Ind-completion $\text{Ind}(\mathcal{C})$ is 06FZ*
also locally small.

Proof. Apply Proposition 9.3.3.1 in the special case where $\kappa = \aleph_0$ and $\lambda = \mu$ is a strongly inaccessible cardinal. $\square$

Variant 9.3.3.3. *Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category. Suppose 063W*
that $\mathcal{C}$ is essentially μ -small, where $\mu > \lambda$ is a regular cardinal of exponential cofinality $\geq \lambda$.
Then $\text{Ind}_\kappa^\lambda(\mathcal{C})$ is also essentially μ -small.

Proof. This is a special case of Proposition 8.4.6.14. $\square$

Warning 9.3.3.4. In contrast with Proposition 9.3.3.1, the conclusion of Variant 9.3.3.3 06G0
 generally does not hold in the limiting case $\lambda = \mu$. For example, if $\mathcal{C}$ is an essentially small ∞ -category, then $\text{Ind}(\mathcal{C})$ is usually not essentially small.

0640 **Definition 9.3.3.5.** Let $\kappa \leq \lambda \leq \mu$ be regular cardinals, where μ is uncountable. We say that a functor $T : \mathcal{QC}_{<\mu} \rightarrow \mathcal{QC}_{<\mu}$ is an $\text{Ind}_\kappa^\lambda$ -completion functor if there exists a natural transformation $\eta : \text{id}_{\mathcal{QC}_{<\mu}} \rightarrow T$ satisfying the following conditions:

- For every μ -small ∞ -category $\mathcal{C}$, the functor $\eta_{\mathcal{C}} : \mathcal{C} \rightarrow T(\mathcal{C})$ exhibits $T(\mathcal{C})$ as an $\text{Ind}_\kappa^\lambda$ -completion of $\mathcal{C}$.
- For every functor $F : \mathcal{C} \rightarrow \mathcal{D}$ between μ -small ∞ -categories, the functor $T(F) : T(\mathcal{C}) \rightarrow T(\mathcal{D})$ is (κ, λ) -finitary.

If these conditions are satisfied, we say that η exhibits T as an $\text{Ind}_\kappa^\lambda$ -completion functor.

0641 **Remark 9.3.3.6.** Let $\kappa \leq \lambda$ be regular cardinals, and let $\mathbb{K}$ be the collection of all λ -small κ -filtered ∞ -categories. Then $T : \mathcal{QC}_{<\mu} \rightarrow \mathcal{QC}_{<\mu}$ is an $\text{Ind}_\kappa^\lambda$ -completion functor (in the sense of Definition 9.3.3.5) if and only if it is a $\mathbb{K}$ -cocompletion functor (in the sense of Definition 8.4.6.3).

0642 **Proposition 9.3.3.7.** Let $\kappa \leq \lambda < \mu$ be regular cardinals. If μ has exponential cofinality $\geq \lambda$, then there exists an $\text{Ind}_\kappa^\lambda$ -completion functor $T : \mathcal{QC}_{<\mu} \rightarrow \mathcal{QC}_{<\mu}$. Moreover, T is uniquely determined up to isomorphism.

Proof. By virtue Corollary 8.4.6.9 (and Remark 9.3.3.6), it will suffice to observe that if $\mathcal{C}$ an essentially μ -small ∞ -category, then $\text{Ind}_\kappa^\lambda(\mathcal{C})$ is also essentially μ -small, which follows from Variant 9.3.3.3. $\square$

0643 **Notation 9.3.3.8.** Let $\kappa \leq \lambda < \mu$ be regular cardinals, where μ has exponential cofinality $\geq \lambda$. Proposition 9.3.3.7 asserts that there exists an essentially unique $\text{Ind}_\kappa^\lambda$ -completion functor $T : \mathcal{QC}_{<\mu} \rightarrow \mathcal{QC}_{<\mu}$. To emphasize its uniqueness, we will typically denote the functor $T(-)$ by $\text{Ind}_\kappa^\lambda(-)$ (compare with Notation 9.3.1.8).

Following the convention of Remark 4.7.0.5, we say that κ is small if it satisfies $\kappa < \Omega$, for some fixed strongly inaccessible cardinal Ω . In this case, we typically denote the functor $\text{Ind}_\kappa^\Omega(-)$ by $\text{Ind}_\kappa(-)$. In the special case where $\kappa = \aleph_0$, we also denote the functor $\text{Ind}_\kappa(-)$ by $\text{Ind}(-)$.

0644 **Remark 9.3.3.9.** Let $\kappa \leq \lambda$ be regular cardinals and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Applying the functor $\text{Ind}_\kappa^\lambda(-)$ of Notation 9.3.3.8 (for any sufficiently large μ), we obtain a functor $\text{Ind}_\kappa^\lambda(F) : \text{Ind}_\kappa^\lambda(\mathcal{C}) \rightarrow \text{Ind}_\kappa^\lambda(\mathcal{D})$, which is characterized (up to isomorphism) by the requirements that it is (κ, λ) -finitary and that the diagram

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{\quad} & \text{Ind}_\kappa^\lambda(\mathcal{C}) \\ \downarrow F & & \downarrow \text{Ind}_\kappa^\lambda(F) \\ \mathcal{D} & \xrightarrow{\quad} & \text{Ind}_\kappa^\lambda(\mathcal{D}) \end{array}$$

commutes up to isomorphism. In other words, $\text{Ind}_\kappa^\lambda(F)$ can be identified with the $\text{Ind}_\kappa^\lambda$ -extension of the composition $\mathcal{C} \xrightarrow{F} \mathcal{D} \rightarrow \text{Ind}_\kappa^\lambda(\mathcal{D})$ (see Definition 9.3.1.12).

Remark 9.3.3.10. Let $\kappa \leq \lambda$ be regular cardinals and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Choose a regular cardinal $\mu \geq \lambda$ such that $\mathcal{C}$ and $\mathcal{D}$ are essentially μ -small, and let

$$h_\bullet^\mathcal{C} : \mathcal{C} \rightarrow \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\mu}) \quad h_\bullet^\mathcal{D} : \mathcal{D} \rightarrow \text{Fun}(\mathcal{D}^{\text{op}}, \mathcal{S}_{<\mu})$$

be covariant Yoneda embeddings for $\mathcal{C}$ and $\mathcal{D}$. By virtue of Example 8.4.4.5, left Kan extension along F determines a μ -cocontinuous functor $F_! : \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\mu}) \rightarrow \text{Fun}(\mathcal{D}^{\text{op}}, \mathcal{S}_{<\mu})$ for which the diagram

$$\begin{array}{ccc} \mathcal{C} & \xrightarrow{h_\bullet^\mathcal{C}} & \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\mu}) \\ \downarrow F & & \downarrow F_! \\ \mathcal{D} & \xrightarrow{h_\bullet^\mathcal{D}} & \text{Fun}(\mathcal{D}^{\text{op}}, \mathcal{S}_{<\mu}) \end{array} \quad (9.11) \quad 0646$$

commutes up to (canonical) isomorphism. Using Proposition 8.4.5.8, we can identify $\text{Ind}_\kappa^\lambda(\mathcal{C})$ and $\text{Ind}_\kappa^\lambda(\mathcal{D})$ with the smallest full subcategories of $\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\mu})$ and $\text{Fun}(\mathcal{D}^{\text{op}}, \mathcal{S}_{<\mu})$ which are closed under λ -small κ -filtered colimits and which contain the essential images of $h_\bullet^\mathcal{C}$ and $h_\bullet^\mathcal{D}$, respectively. It follows from the commutativity of the diagram (9.11) that $F_!$ restricts to a functor $\text{Ind}_\kappa^\lambda(\mathcal{C}) \rightarrow \text{Ind}_\kappa^\lambda(\mathcal{D})$, which we can identify with the functor $\text{Ind}_\kappa^\lambda(F)$ of Remark 9.3.3.9.

Exercise 9.3.3.11. Let $\kappa \leq \lambda$ be regular cardinals and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories which admits a right adjoint $G : \mathcal{D} \rightarrow \mathcal{C}$. Show that $\text{Ind}_\kappa^\lambda(G) : \text{Ind}_\kappa^\lambda(\mathcal{D}) \rightarrow \text{Ind}_\kappa^\lambda(\mathcal{C})$ is right adjoint to $\text{Ind}_\kappa^\lambda(F) : \text{Ind}_\kappa^\lambda(\mathcal{C}) \rightarrow \text{Ind}_\kappa^\lambda(\mathcal{D})$. 0647

Proposition 9.3.3.12. Let $\kappa \leq \lambda < \mu$ be regular cardinals, where μ has exponential cofinality $\geq \lambda$. Then the functor 0648

$$\text{Ind}_\kappa^\lambda : \mathcal{QC}_{<\mu} \rightarrow \mathcal{QC}_{<\mu}$$

is (λ, μ) -finitary: that is, it commutes with μ -small λ -filtered colimits.

Proof. By virtue of Remark 9.3.3.6, this is a special case of Corollary 9.1.9.11. $\square$

We now study a somewhat different way of articulating the functoriality of Ind-completion: it is a construction which makes sense in families.

06G1 **Definition 9.3.3.13.** Let $\kappa \leq \lambda$ be regular cardinals and suppose we are given a commutative diagram of simplicial sets

$$\begin{array}{ccc} \mathcal{E} & \xrightarrow{H} & \widehat{\mathcal{E}} \\ & \searrow U \quad \swarrow \widehat{U} & \\ & \mathcal{C}, & \end{array}$$

where U and $\widehat{U}$ are inner fibrations. We will say that H *exhibits $\widehat{U}$ as an $\text{Ind}_\kappa^\lambda$ -completion of U* if the following condition is satisfied:

(*) For every n -simplex $\sigma : \Delta^n \rightarrow \mathcal{C}$, the functor

$$H_\sigma : \Delta^n \times_{\mathcal{C}} \mathcal{E} \rightarrow \Delta^n \times_{\mathcal{C}} \widehat{\mathcal{E}}$$

exhibits the ∞ -category $\Delta^n \times_{\mathcal{C}} \widehat{\mathcal{E}}$ as an $\text{Ind}_\kappa^\lambda$ -completion of $\Delta^n \times_{\mathcal{C}} \mathcal{E}$, in the sense of Variant 9.3.1.7.

06G2 **Warning 9.3.3.14.** The terminology of Definition 9.3.3.13 is potentially confusing. Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of ∞ -categories. We have now assigned two different meanings to the term $\text{Ind}_\kappa^\lambda$ -completion of U :

- The $\text{Ind}_\kappa^\lambda$ -completion of U as a *functor* (in the sense of Remark 9.3.3.9): this is a functor $\text{Ind}_\kappa^\lambda(U) : \text{Ind}_\kappa^\lambda(\mathcal{E}) \rightarrow \text{Ind}_\kappa^\lambda(\mathcal{C})$.
- The $\text{Ind}_\kappa^\lambda$ -completion of U as an *inner fibration* (in the sense of Definition 9.3.3.13): this is an inner fibration $\widehat{U} : \widehat{\mathcal{E}} \rightarrow \mathcal{C}$.

Beware that these are distinct notions. However, they are closely related: one can arrange that they fit into a commutative diagram

$$\begin{array}{ccc} \widehat{\mathcal{E}} & \longrightarrow & \text{Ind}_\kappa^\lambda(\mathcal{E}) \\ \downarrow \widehat{U} & & \downarrow \text{Ind}_\kappa^\lambda(U) \\ \mathcal{C} & \longrightarrow & \text{Ind}_\kappa^\lambda(\mathcal{C}) \end{array}$$

which is often (but not always) a categorical pullback square. See Proposition [?].

Proposition 9.3.3.15. *Let $\kappa \leq \lambda$ be regular cardinals and suppose we are given a commu- 06G3
tative diagram of simplicial sets*

$$\begin{array}{ccc} \mathcal{E} & \xrightarrow{H} & \widehat{\mathcal{E}} \\ & \searrow U \quad \swarrow \widehat{U} & \\ & \mathcal{C}, & \end{array}$$

where U and $\widehat{U}$ are inner fibrations. Then H exhibits $\widehat{U}$ as an $\text{Ind}_\kappa^\lambda$ -completion of U if and only if the following pair of conditions is satisfied:

- (1) The inner fibration $\widehat{U}$ is (κ, λ) -cocomplete (in the sense of Definition 9.2.9.4).
- (2) For each vertex $C \in \mathcal{C}$, the map of fibers $H_C : \mathcal{E}_C \rightarrow \widehat{\mathcal{E}}_C$ exhibits $\widehat{\mathcal{E}}_C$ as an $\text{Ind}_\kappa^\lambda$ -completion of $\mathcal{E}_C$ (in the sense of Variant 9.3.1.7).
- (3) For every edge $e : C \rightarrow C'$ of $\mathcal{C}$ and every object $X \in \mathcal{E}_C$, the image $H(X)$ is (κ, λ) -compact as an object of the ∞ -category $\Delta^1 \times_{\mathcal{C}} \mathcal{E}$.

Proof. If H exhibits $\widehat{U}$ as an $\text{Ind}_\kappa^\lambda$ -completion of U , then conditions (1) and (2) are immediate from the definitions and (3) follows from the recognition principle of Proposition 9.3.2.3. We now prove the converse. Assume that conditions (1), (2), and (3) are satisfied and let σ be an n -simplex of $\mathcal{C}$; we wish to show that the induced map $H_\sigma : \mathcal{E}_\sigma \rightarrow \widehat{\mathcal{E}}_\sigma$ exhibits $\widehat{\mathcal{E}}_\sigma$ as an $\text{Ind}_\kappa^\lambda$ -completion of $\mathcal{E}_\sigma$. Without loss of generality, we may assume that $\mathcal{C} = \Delta^n$ is a standard simplex and that σ is the identity map; in this case, we wish to show that H exhibits $\widehat{\mathcal{E}}$ as an $\text{Ind}_\kappa^\lambda$ -completion of $\mathcal{E}$. It follows from assumption (1) that $\widehat{\mathcal{E}}$ is (κ, λ) -cocomplete. Moreover, for $0 \leq i \leq n$, the full subcategory $\widehat{\mathcal{E}}_i = \widehat{U}^{-1}\{i\}$ is closed under the formation of λ -small κ -filtered colimits in $\widehat{\mathcal{E}}_i$. Assumption (2) guarantees that each $\widehat{\mathcal{E}}_i$ is generated under λ -small κ -filtered colimits by the essential image of $\mathcal{E}_i$. To complete the proof, it will suffice to show that for each object $X \in \mathcal{E}$, the image $H(X) \in \widehat{\mathcal{E}}$ is (κ, λ) -compact (see Proposition 9.3.2.3). By virtue of Remark 9.2.9.13, this is a reformulation of assumption (3). $\square$

Remark 9.3.3.16. Let $\kappa \leq \lambda$ be regular cardinals, let $\mathbb{K}$ be the collection of all λ -small 06G4
 κ -filtered ∞ -categories, and suppose we are given a commutative diagram of simplicial sets

$$\begin{array}{ccc} \mathcal{E} & \xrightarrow{H} & \widehat{\mathcal{E}} \\ & \searrow U \quad \swarrow \widehat{U} & \\ & \mathcal{C}, & \end{array}$$

where U and $\widehat{U}$ are inner fibrations. Proposition 9.3.3.15 asserts that the following conditions are equivalent:

- The morphism H exhibits $\widehat{U}$ as an $\text{Ind}_\kappa^\lambda$ -completion of U , in the sense of Definition 9.3.3.13.
- The morphism H exhibits $\widehat{U}$ as a fiberwise $\mathbb{K}$ -cocompletion of U , in the sense of Definition 8.7.1.1.

06G5 **Corollary 9.3.3.17** (Existence). *Let $\kappa \leq \lambda$ be regular cardinals and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. Then there exists a diagram*

$$\begin{array}{ccc} \mathcal{E} & \xrightarrow{H} & \widehat{\mathcal{E}} \\ & \searrow U & \swarrow \widehat{U} \\ & \mathcal{C} & \end{array}$$

which exhibits $\widehat{U}$ as an $\text{Ind}_\kappa^\lambda$ -completion of U .

Proof. Combine Theorem 8.7.4.1 with Remark 9.3.3.16. □

In the situation of Corollary 9.3.3.17, the inner fibration $\widehat{U} : \widehat{\mathcal{E}} \rightarrow \mathcal{C}$ is uniquely determined up to equivalence. This is a consequence of the following universal property:

06G6 **Corollary 9.3.3.18** (Uniqueness). *Let $\kappa \leq \lambda$ be regular cardinals and suppose we are given a commutative diagram*

$$\begin{array}{ccc} \mathcal{E} & \xrightarrow{H} & \widehat{\mathcal{E}} \\ & \searrow U & \swarrow \widehat{U} \\ & \mathcal{C}, & \end{array}$$

where U and $\widehat{U}$ are inner fibrations and H exhibits $\widehat{U}$ as an $\text{Ind}_\kappa^\lambda$ -completion of U . Let $V : \mathcal{D} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets which is (κ, λ) -cocomplete, and let $\text{Fun}'_{/\mathcal{C}}(\widehat{\mathcal{E}}, \mathcal{D})$ be the full subcategory of $\text{Fun}_{/\mathcal{C}}(\widehat{\mathcal{E}}, \mathcal{D})$ spanned by those objects F such that, for each vertex $C \in \mathcal{C}$, the map of fibers $F_C : \widehat{\mathcal{E}}_C \rightarrow \mathcal{D}_C$ is (κ, λ) -finitary. Then composition with H induces an equivalence of ∞ -categories

$$\text{Fun}'_{/\mathcal{C}}(\widehat{\mathcal{E}}, \mathcal{D}) \rightarrow \text{Fun}_{/\mathcal{C}}(\mathcal{E}, \mathcal{D}).$$

Proof. Combine Theorem 8.7.1.14 with Remark 9.3.3.16 (and Remark 9.2.9.8). □

Corollary 9.3.3.19. *Let $\kappa \leq \lambda$ be regular cardinals and suppose we are given a commutative 06G7 diagram*

$$\begin{array}{ccc} \mathcal{E} & \xrightarrow{H} & \widehat{\mathcal{E}} \\ & \searrow U \quad \swarrow \widehat{U} & \\ & \mathcal{C}, & \end{array}$$

where U and $\widehat{U}$ are inner fibrations and H exhibits $\widehat{U}$ as an $\mathrm{Ind}_\kappa^\lambda$ -completion of U . If U is a cocartesian fibration, then $\widehat{U}$ is also a cocartesian fibration. In this case, the diagram

$$\begin{array}{ccc} & \mathcal{C} & \\ \mathrm{Tr}_{\mathcal{E}/c} \swarrow & & \searrow \mathrm{Tr}_{\widehat{\mathcal{E}}/c} \\ \mathcal{QC}_{<\mu} & \xrightarrow{\mathrm{Ind}_\kappa^\lambda} & \mathcal{QC}_{<\mu} \end{array}$$

commutes up to isomorphism, where the vertical maps are the covariant transport representations of U and $\widehat{U}$, respectively. Here $\mu > \lambda$ is any cardinal of exponential cofinality $\geq \lambda$ for which U is essentially μ -small.

Proof. Combine Proposition [?] with Remark 9.3.3.16. □

Corollary 9.3.3.20. *Let $\kappa \leq \lambda$ be regular cardinals and suppose we are given a commutative 06G8 diagram*

$$\begin{array}{ccc} \mathcal{E} & \xrightarrow{H} & \widehat{\mathcal{E}} \\ & \searrow U \quad \swarrow \widehat{U} & \\ & \mathcal{C}, & \end{array}$$

where U and $\widehat{U}$ are inner fibrations and H exhibits $\widehat{U}$ as an $\mathrm{Ind}_\kappa^\lambda$ -completion of U . If U is a cocartesian fibration, then $\widehat{U}$ is also a cocartesian fibration. In this case, the diagram

$$\begin{array}{ccc} & \mathcal{C} & \\ \mathrm{Tr}_{\mathcal{E}/c} \swarrow & & \searrow \mathrm{Tr}_{\widehat{\mathcal{E}}/c} \\ \mathcal{QC}_{<\mu} & \xrightarrow{\mathrm{Ind}_\kappa^\lambda} & \mathcal{QC}_{<\mu} \end{array}$$

commutes up to isomorphism, where the vertical maps are the covariant transport representations of U and $\widehat{U}$, respectively. Here $\mu > \lambda$ is any cardinal of exponential cofinality $\geq \lambda$ for which U is essentially μ -small.

Proof. Combine Proposition [?] with Remark 9.3.3.16. $\square$

06G9 **Remark 9.3.3.21.** Let $\kappa \leq \lambda < \mu$ be regular cardinals, where μ has exponential cofinality $\geq \lambda$. Then the functor $\text{Ind}_\kappa^\lambda : \mathcal{QC}_{<\mu} \rightarrow \mathcal{QC}_{<\mu}$ of Notation 9.3.3.8 can be characterized (up to isomorphism) by the conclusion of either Corollary 9.3.3.19 or Corollary 9.3.3.20.

9.3.4 Flat Functors

065H Let $\mathcal{C}$ be an essentially small ∞ -category. Our goal in this section is to give a more explicit description of the Ind-completion $\text{Ind}(\mathcal{C})$ of Notation 9.3.1.2.

065J **Definition 9.3.4.1.** Let $\mathcal{D}$ be an ∞ -category. We say that a functor $\mathcal{F} : \mathcal{D} \rightarrow \mathcal{S}$ is *flat* if the ∞ -category of elements $\int_{\mathcal{D}} \mathcal{F}$ is cofiltered (see Definition 5.6.2.1). We let $\text{Fun}^b(\mathcal{D}, \mathcal{S})$ denote the full subcategory of $\text{Fun}(\mathcal{D}, \mathcal{S})$ spanned by the flat functors.

065K **Remark 9.3.4.2.** Definition 9.3.4.1 has a counterpart in classical category theory. If $\mathcal{D}$ is an ordinary category, we say that a functor $\mathcal{F} : \mathcal{D} \rightarrow \text{Set}$ is *flat* if the category of elements $\int_{\mathcal{D}} \mathcal{F}$ is cofiltered (Definition 5.2.6.1). It follows from Corollary 9.1.2.8 that this condition is satisfied if and only if the nerve

$$\mathbf{N}_\bullet(\mathcal{F}) : \mathbf{N}_\bullet(\mathcal{D}) \rightarrow \mathbf{N}_\bullet(\text{Set}) \subset \mathcal{S}$$

is a flat functor of ∞ -categories, in the sense of Definition 9.3.4.1. We will see below that, up to isomorphism, every flat functor $\mathbf{N}_\bullet(\mathcal{D}) \rightarrow \mathcal{S}$ can be obtained in this way (Remark 9.3.4.20). Consequently, Definition 9.3.4.1 can be regarded as a generalization of its classical counterpart.

065L **Example 9.3.4.3** (Flat Modules as Flat Functors). Let R be an associative ring and let $\mathcal{C}$ be the category of free left R -modules of finite rank. Then a functor $\mathcal{F} : \mathcal{C}^{\text{op}} \rightarrow \text{Set}$ is flat if and only if it has the form $\text{Hom}_R(\bullet, M)$, where M is a flat left R -module. This is a reformulation of Lazard's characterization of flat modules (Variant 9.3.2.9), by virtue of Remark 9.3.4.6 below.

065M **Warning 9.3.4.4.** The notion of flat functor $\mathcal{F} : \mathcal{D} \rightarrow \mathcal{S}$ introduced in Definition 9.3.4.1 is unrelated to the notion of flat inner fibration $U : \mathcal{E} \rightarrow \mathcal{C}$ introduced in Definition 8.7.5.1.

We can now state a preliminary version of our main result:

Proposition 9.3.4.5. *Let $\mathcal{C}$ be an essentially small ∞ -category. Then the covariant Yoneda embedding $h_\bullet : \mathcal{C} \rightarrow \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$ factors through $\text{Fun}^b(\mathcal{C}^{\text{op}}, \mathcal{S})$, and exhibits $\text{Fun}^b(\mathcal{C}^{\text{op}}, \mathcal{S})$ as an Ind-completion of $\mathcal{C}$ (in the sense of Definition 9.3.1.1).* 065N

Remark 9.3.4.6. Let $\mathcal{C}$ be an essentially small ∞ -category, and let us abuse notation by identifying $\mathcal{C}$ with a full subcategory of $\text{Ind}(\mathcal{C})$. Stated more informally, Proposition 9.3.4.5 asserts that the functor 065P

$$\text{Ind}(\mathcal{C}) \rightarrow \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \quad C \mapsto \text{Hom}_{\text{Ind}(\mathcal{C})}(\bullet, C)$$

is fully faithful, and that its essential image is spanned by the flat functors from $\mathcal{C}^{\text{op}}$ to $\mathcal{S}$. In particular, a functor $\mathcal{F} : \mathcal{C}^{\text{op}} \rightarrow \mathcal{S}$ is flat if and only if it is representable by an object of $\text{Ind}(\mathcal{C})$.

Definition 9.3.4.1 is a special case of the following:

Definition 9.3.4.7. Let $\mathcal{D}$ be an ∞ -category and let κ and λ be regular cardinals, where λ is uncountable. We say that a functor $\mathcal{F} : \mathcal{D} \rightarrow \mathcal{S}_{<\lambda}$ is κ -flat if the ∞ -category of elements $\int_{\mathcal{D}} \mathcal{F}$ is κ -cofiltered (Definition 9.1.1.4). We let $\text{Fun}^{\kappa\text{-flat}}(\mathcal{D}, \mathcal{S}_{<\lambda})$ denote the full subcategory of $\text{Fun}(\mathcal{D}, \mathcal{S}_{<\lambda})$ spanned by those functors which are κ -flat. 065Q

Remark 9.3.4.8. In the situation of Definition 9.3.4.7, any functor from $\mathcal{D}$ to $\mathcal{S}_{<\lambda}$ can also be regarded as a functor from $\mathcal{D}$ to $\mathcal{S}_{<\lambda'}$, for any $\lambda' \geq \lambda$. In this case, replacing λ by λ' does not change the ∞ -category of elements $\int_{\mathcal{D}} \mathcal{F}$. Consequently, the condition that $\mathcal{F}$ is κ -flat does not depend on λ . 065R

Example 9.3.4.9. A functor of ∞ -categories $\mathcal{F} : \mathcal{D} \rightarrow \mathcal{S}$ is flat (in the sense of Definition 9.3.4.1) if and only if it is $\aleph_0$ -flat (in the sense of Definition 9.3.4.7). 065S

Remark 9.3.4.10 (Monotonicity). Let λ be an uncountable cardinal and let $\mathcal{F} : \mathcal{D} \rightarrow \mathcal{S}_{<\lambda}$ be a functor of ∞ -categories. If $\mathcal{F}$ is κ -flat (for some regular cardinal κ), then it is also κ' -flat for every regular cardinal $\kappa' \leq \kappa$ (see Remark 9.1.1.10). In particular, every κ -flat functor $\mathcal{F} : \mathcal{D} \rightarrow \mathcal{S}_{<\lambda}$ is flat. 065T

Example 9.3.4.11 (Corepresentable Functors). Let λ be an uncountable cardinal and let $\mathcal{D}$ be an ∞ -category. If $\mathcal{F} : \mathcal{D} \rightarrow \mathcal{S}_{<\lambda}$ is corepresentable by an object of $\mathcal{D}$, then it is κ -flat for every regular cardinal κ : this follows from Example 9.1.1.6, since the ∞ -category $\int_{\mathcal{D}} \mathcal{F}$ has an initial object (Proposition 5.6.6.21). 065U

Remark 9.3.4.12. Example 9.3.4.11 admits a partial converse. Let λ be an uncountable regular cardinal and let $\mathcal{D}$ be an idempotent-complete ∞ -category which is essentially λ -small. For any functor $\mathcal{F} : \mathcal{D} \rightarrow \mathcal{S}_{<\lambda}$, the ∞ -category of elements $\int_{\mathcal{D}} \mathcal{F}$ is also idempotent-complete (Corollary 8.5.4.24) and essentially λ -small (Corollary 4.7.9.12). It follows that $\int_{\mathcal{D}} \mathcal{F}$ is 065V

λ -cofiltered if and only if it has an initial object (Proposition 9.1.8.11). In other words, $\mathcal{F}$ is λ -flat if and only if it is corepresentable.

More generally, if we assume that $\mathcal{D}$ is essentially λ -small (but not necessarily idempotent-complete), then a functor $\mathcal{F} : \mathcal{D} \rightarrow \mathcal{S}_{<\lambda}$ is λ -flat if and only if it is a retract of a corepresentable functor. This follows from Theorem 9.3.4.14 (applied in the special case $\kappa = \lambda$), together with Example 9.3.1.10.

065W Remark 9.3.4.13. Let λ be an uncountable regular cardinal and let $\mathcal{F} : \mathcal{C}^{\text{op}} \rightarrow \mathcal{S}_{<\lambda}$ be a functor of ∞ -categories. Then $\mathcal{F}$ can be realized as the contravariant transport representation of a right fibration $U : \mathcal{E} \rightarrow \mathcal{C}$, which is well-defined up to equivalence (Proposition 8.6.8.3). In this case, the functor $\mathcal{F}$ is κ -flat (in the sense of Definition 9.3.4.7) if and only if the ∞ -category $\mathcal{E}$ is κ -filtered (in the sense of Variant 9.1.1.4).

In particular, if $\mathcal{C}$ is locally λ -small and $h_{\bullet} : \mathcal{C} \rightarrow \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$ is a covariant Yoneda embedding for $\mathcal{C}$, then $\mathcal{F}$ is κ -flat if and only if the ∞ -category $\mathcal{C} \times_{\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})} \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})_{/\mathcal{F}}$ is κ -filtered. See Corollary 8.4.2.7.

Let λ be an uncountable regular cardinal and let $\mathcal{C}$ be an ∞ -category which is locally λ -small. It follows from Example 9.3.4.11 that the covariant Yoneda embedding

$$h_{\bullet} : \mathcal{C} \rightarrow \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$$

factors through the full subcategory $\text{Fun}^{\kappa\text{-b}}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$, for every regular cardinal κ . Following the convention of Remark 4.7.0.5, we can regard Proposition 9.3.4.5 as a special case of the following:

065X Theorem 9.3.4.14. *Let $\kappa \leq \lambda$ be regular cardinals, where λ is uncountable, and let $\mathcal{C}$ be an ∞ -category which is essentially λ -small. Then the covariant Yoneda embedding $h_{\bullet} : \mathcal{C} \rightarrow \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$ factors through $\text{Fun}^{\kappa\text{-b}}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$, and exhibits $\text{Fun}^{\kappa\text{-b}}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$ as an $\text{Ind}_{\kappa}^{\lambda}$ -completion of $\mathcal{C}$ (in the sense of Variant 9.3.1.7).*

Before giving the proof of Theorem 9.3.4.14, let us record some consequences.

06GA Corollary 9.3.4.15. *Let $\kappa \leq \lambda$ be regular cardinals, where λ is uncountable, let $\mathcal{C}$ be an ∞ -category which is essentially λ -small, and let $h : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ be a functor which exhibits $\widehat{\mathcal{C}}$ as an $\text{Ind}_{\kappa}^{\lambda}$ -completion of $\mathcal{C}$. Then, for every object $X \in \widehat{\mathcal{C}}$, the ∞ -category $\mathcal{E} = \mathcal{C} \times_{\widehat{\mathcal{C}}} \widehat{\mathcal{C}}_{/X}$ is κ -filtered and essentially λ -small. Moreover, the tautological map $\mathcal{E}^{\triangleright} \rightarrow \widehat{\mathcal{C}}_{/X}^{\triangleright} \rightarrow \widehat{\mathcal{C}}$ is a colimit diagram. In particular, the object X is a colimit of the essentially λ -small κ -filtered diagram $\mathcal{E} \rightarrow \mathcal{C} \xrightarrow{h} \widehat{\mathcal{C}}$.*

Proof. By virtue of Theorem 9.3.4.14, we may assume without loss of generality that $\widehat{\mathcal{C}} = \text{Fun}^{\kappa\text{-b}}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$ and that h is the covariant Yoneda embedding. In this case, we can identify X with a κ -flat functor $\mathcal{F} : \mathcal{C}^{\text{op}} \rightarrow \mathcal{S}_{<\lambda}$, so that the projection map $U : \mathcal{E} \rightarrow \mathcal{C}$ is an

essentially λ -small right fibration with contravariant transport representation $\mathcal{F}$ (Corollary 8.4.2.7). Since $\mathcal{F}$ is κ -flat, the ∞ -category $\mathcal{E}$ is κ -filtered. Since $\mathcal{C}$ is essentially λ -small, Corollary 4.7.9.12 guarantees that $\mathcal{E}$ is also essentially λ -small. The last assertion follows from the density of the covariant Yoneda embedding (Variant 8.4.2.4). $\square$

Corollary 9.3.4.16. *Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category. Then every object of $\mathrm{Ind}_\kappa^\lambda(\mathcal{C})$ can be realized as the colimit of a λ -small κ -filtered diagram $\mathcal{K} \rightarrow \mathcal{C}$.* 0664

Proof. Without loss of generality, we may assume that λ is uncountable (see Example 9.3.1.10). Fix a regular cardinal $\mu > \lambda$ having exponential cofinality $\geq \lambda$ such that $\mathcal{C}$ is μ -small. Then $\lambda \triangleleft \mu$ (Proposition 9.1.7.8), so $\mathcal{C}$ can be realized as the colimit of a μ -small, λ -filtered diagram $\{\mathcal{C}_\alpha\}$ in the ∞ -category $\mathcal{QC}_{<\mu}$ (see Variant 9.1.7.21), where each $\mathcal{C}_\alpha$ is λ -small. It follows from Proposition 9.3.3.12 that every object of $\mathrm{Ind}_\kappa^\lambda(\mathcal{C})$ can be lifted to an object of $\mathrm{Ind}_\kappa^\lambda(\mathcal{C}_\alpha)$, for some index α . We may therefore replace $\mathcal{C}$ by $\mathcal{C}_\alpha$, and thereby reduce to the case where $\mathcal{C}$ is λ -small. In this case, the desired result follows from Corollary 9.3.4.15. $\square$

Our proof of Theorem 9.3.4.14 will require some preliminaries.

Lemma 9.3.4.17. *Let λ be an uncountable regular cardinal and let $\mathcal{C}$ be an ∞ -category which is essentially λ -small. Then there exists a λ -cocontinuous functor* 065Y

$$T : \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda}) \rightarrow \mathcal{QC}_{<\lambda}$$

which carries each $\mathcal{F} : \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{S}_{<\lambda}$ to an ∞ -category $\mathcal{E}_{\mathcal{F}}$ which is equipped with a right fibration $\mathcal{E}_{\mathcal{F}} \rightarrow \mathcal{C}$ having contravariant transport representation $\mathcal{F}$.

Proof. Let $\mathcal{E}$ denote the oriented fiber product $\mathcal{C} \tilde{\times}_{\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})} \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})$, and let $U : \mathcal{E} \rightarrow \mathcal{C}$ and $V : \mathcal{E} \rightarrow \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})$ be the projection maps. For each object $\mathcal{F} \in \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})$, let $\mathcal{E}_{\mathcal{F}}$ denote the fiber $V^{-1}\{\mathcal{F}\}$, and let $U_{\mathcal{F}} : \mathcal{E}_{\mathcal{F}} \rightarrow \mathcal{C}$ be the restriction of U . Then $U_{\mathcal{F}}$ is a right fibration with contravariant transport representation $\mathcal{F}$ (Corollary 8.4.2.7). In particular, the right fibration $U_{\mathcal{F}}$ is essentially λ -small, so the ∞ -category $\mathcal{E}_{\mathcal{F}}$ is essentially λ -small (Proposition 4.7.9.10). It follows that V is a cocartesian fibration (Corollary 5.3.7.3) which admits a covariant transport representation

$$T : \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda}) \rightarrow \mathcal{QC}_{<\lambda} \quad \mathcal{F} \mapsto \mathcal{E}_{\mathcal{F}}.$$

We will complete the proof by showing that the functor T is λ -cocontinuous.

Fix a λ -small ∞ -category $\mathcal{K}$ and a (levelwise) colimit diagram $\overline{G} : \mathcal{K}^{\triangleright} \rightarrow \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})$; we wish to show that $T \circ \overline{G}$ is a colimit diagram in $\mathcal{QC}_{<\lambda}$. Set $\mathcal{E}' = \mathcal{C} \tilde{\times}_{\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})} \mathcal{K}^{\triangleright}$, so that $T \circ \overline{G}$ is a covariant transport representation for the projection map $V' : \mathcal{E}' \rightarrow \mathcal{K}^{\triangleright}$. Let z denote the cone point of $\mathcal{K}^{\triangleright} = \mathcal{K} \star \{z\}$ and define

$$\mathcal{E}'_0 = \mathcal{E}' \times_{\mathcal{K}^{\triangleright}} \mathcal{K} \quad \mathcal{E}'_z = \mathcal{E}' \times_{\mathcal{K}^{\triangleright}} \{z\},$$

so that the cocartesian fibration V' admits a covariant refraction diagram $\mathrm{Rf} : \mathcal{E}'_0 \rightarrow \mathcal{E}'_z$ (see Definition 7.4.5.8). Let $U' : \mathcal{E}' \rightarrow \mathcal{C}$ be projection onto the first factor and let W be the collection of all morphisms e of $\mathcal{E}'_0$ such that $U'(e)$ is an identity morphism in $\mathcal{C}$. It follows from Corollary 5.3.7.3 that a morphism e of $\mathcal{E}'_0$ is V' -cocartesian if and only if $U(e)$ is an isomorphism in $\mathcal{C}$: that is, if and only if e is isomorphic (as an object of $\mathrm{Fun}(\Delta^1, \mathcal{E}'_0)$) to an element of W . By virtue of Theorem 7.4.5.13, it will suffice to show that the functor Rf exhibits the ∞ -category $\mathcal{E}'_v$ as a localization of $\mathcal{E}'_0$ with respect to W .

Let $h : \Delta^1 \times \mathcal{E}'_0 \rightarrow \mathcal{E}'$ be a natural transformation which exhibits Rf as a covariant refraction diagram for V' (see Definition 7.4.5.8). Then h carries each object $E \in \mathcal{E}'_0$ to a V' -cocartesian morphism $h_E : E \rightarrow \mathrm{Rf}(E)$, so that $U'(h_E)$ is an isomorphism in $\mathcal{C}$. We may therefore assume (replacing Rf by an isomorphic functor if necessary) that the composition $(U' \circ h) : \Delta^1 \times \mathcal{E}'_0 \rightarrow \mathcal{C}$ factors through $\mathcal{E}'_0$ (so that each $U'(h_E)$ is an identity morphism in $\mathcal{C}$). Then, for each $C \in \mathcal{C}$, Rf restricts to a functor

$$\mathrm{Rf}_C : \{C\} \times_{\mathcal{C}} \mathcal{E}'_0 \rightarrow \{C\} \times_{\mathcal{C}} \mathcal{E}'_z$$

which is a covariant refraction diagram for the left fibration $\{C\} \tilde{\times}_{\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})} \mathcal{K}^{\triangleright} \rightarrow \mathcal{K}^{\triangleright}$. Our assumption that $\overline{G}$ is a (levelwise) colimit diagram then guarantees that Rf_C is a weak homotopy equivalence: that is, it exhibits the Kan complex $\{C\} \times_{\mathcal{C}} \mathcal{E}'_z$ as a localization of $\{C\} \times_{\mathcal{C}} \mathcal{E}'_0$ with respect to the collection W_C of all morphisms of $\{C\} \times_{\mathcal{C}} \mathcal{E}'_0$ (Theorem 7.4.5.13). Applying Theorem 6.3.4.1, we conclude that Rf exhibits $\mathcal{E}'_v$ as a localization of $\mathcal{E}'_0$ with respect to the collection of morphisms $W = \bigcup_{C \in \mathcal{C}} W_C$, as desired. $\square$

065Z **Lemma 9.3.4.18.** *Let κ and λ be regular cardinals, where λ is uncountable. Then, for every ∞ -category $\mathcal{C}$, the full subcategory $\mathrm{Fun}^{\kappa\text{-}\flat}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda}) \subseteq \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})$ is closed under λ -small κ -filtered colimits.*

Proof. Enlarging λ if necessary, we may assume that $\mathcal{C}$ is essentially λ -small. Let $T : \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda}) \rightarrow \mathcal{QC}_{<\lambda}$ be as in Lemma 9.3.4.17. Then a functor $\mathcal{F} : \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{S}_{<\lambda}$ belongs to $\mathrm{Fun}^{\kappa\text{-}\flat}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})$ if and only if the ∞ -category $T(\mathcal{F})$ is κ -filtered (Remark 9.3.4.13). Since T is λ -cocontinuous, the collection of objects which satisfy this condition is closed under λ -small κ -filtered colimits (Corollary 9.1.5.16). $\square$

0660 **Lemma 9.3.4.19.** *Let $\kappa \leq \lambda$ be regular cardinals, where λ is uncountable. Let $\mathcal{C}$ be an ∞ -category which is essentially λ -small and let $h_{\bullet} : \mathcal{C} \rightarrow \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})$ be a covariant Yoneda embedding for $\mathcal{C}$. Then a functor $\mathcal{F} : \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{S}_{<\lambda}$ is λ -flat if and only if there exists a λ -small κ -filtered diagram $U : \mathcal{E} \rightarrow \mathcal{C}$ such that $\mathcal{F}$ is the colimit of $(h_{\bullet} \circ U) : \mathcal{E} \rightarrow \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})$.*

Proof. The “if” direction follows by combining Lemma 9.3.4.18 with Example 9.3.4.11. For the converse, we proceed as in the proof of Corollary 9.3.4.15. Assume that $\mathcal{F}$ is κ -flat, so that the ∞ -category

$$\mathcal{E} = \mathcal{C} \times_{\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})} \mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda}) / \mathcal{F}$$

is κ -filtered (Remark 9.3.4.13). Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be the projection map. Since the covariant Yoneda embedding $h_\bullet$ is dense (Variant 8.4.2.4), $\mathcal{F}$ is a colimit of the diagram $h_\bullet \circ U$. To complete the proof, it will suffice to show that the ∞ -category $\mathcal{E}$ is essentially λ -small. This follows from Corollary 4.7.9.12, since $\mathcal{C}$ is essentially λ -small and the right fibration U is essentially λ -small. $\square$

Remark 9.3.4.20. Let $\mathcal{C}$ be an ∞ -category and let $\mathcal{F} : \mathcal{C} \rightarrow \mathcal{S}_{<\lambda}$ be a flat functor. Assume 0661 that $\mathcal{C}$ is locally n -truncated for some integer n . Then, for every object $C \in \mathcal{C}$, the Kan complex $\mathcal{F}(C)$ is n -truncated. To prove this, we can apply Lemma 9.3.4.19 (possibly after enlarging λ) to realize $\mathcal{F}$ as a levelwise filtered colimit of corepresentable functors. Since the collection of n -truncated Kan complexes is closed under filtered colimits (Variant 9.1.9.3), we may assume without loss of generality that $\mathcal{F}$ is corepresentable by an object $D \in \mathcal{C}$. In this case, we are reduced to the assertion that the every morphism space $\mathrm{Hom}_{\mathcal{C}}(D, C)$ is n -truncated, which follows from our assumption that $\mathcal{C}$ is locally n -truncated. See Proposition 9.3.2.13 for a closely related statement.

Corollary 9.3.4.21. Let κ be a regular cardinal and let $\mathcal{F} : \mathcal{C} \rightarrow \mathcal{S}_{<\lambda}$ be a κ -flat functor, 0662 where λ is an uncountable cardinal. Then $\mathcal{F}$ preserves all κ -small limits which exist in $\mathcal{D}$.

Proof. Enlarging λ if necessary, we may assume that λ is regular, that $\mathcal{C}$ is essentially λ -small, and that λ has exponential cofinality $\geq \kappa$ (so that the ∞ -category $\mathcal{S}_{<\lambda}$ is κ -complete). Using Lemma 9.3.4.19, we can realize $\mathcal{F}$ as the colimit of a λ -small κ -filtered diagram

$$\mathcal{K} \rightarrow \mathrm{Fun}(\mathcal{C}, \mathcal{S}_{<\lambda}) \quad \alpha \mapsto \mathcal{F}_\alpha,$$

where each $\mathcal{F}_\alpha$ is corepresentable by an object of $\mathcal{C}$ and therefore preserves all limits which exist in $\mathcal{C}$ (Proposition 7.4.1.18). Since $\mathcal{K}$ -indexed colimits commute with κ -small limits in the ∞ -category $\mathcal{S}_{<\lambda}$ (Proposition 9.1.5.10), it follows that the functor $\mathcal{F}$ preserves κ -small limits. $\square$

Remark 9.3.4.22. If the ∞ -category $\mathcal{C}$ is κ -complete, then the converse of Corollary 9.3.5.23 0663 is also true: every κ -continuous functor $\mathcal{F} : \mathcal{C} \rightarrow \mathcal{S}_{<\lambda}$ is κ -flat. See Corollary 9.3.5.23.

Proof of Theorem 9.3.4.14. Let $\kappa \leq \lambda$ be regular cardinals, where λ is uncountable, let $\mathcal{C}$ be an ∞ -category which is essentially λ -small. We wish to show that the covariant Yoneda embedding $h_\bullet : \mathcal{C} \rightarrow \mathrm{Fun}^{\kappa-b}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})$ exhibits $\mathrm{Fun}^{\kappa-b}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})$ as an $\mathrm{Ind}_\kappa^\lambda$ -completion of $\mathcal{C}$. By virtue of Proposition 8.4.5.8, it will suffice to show that $\mathrm{Fun}^{\kappa-b}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})$ is the smallest full subcategory of $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})$ which contains all representable functors and is closed under λ -small κ -filtered colimits. This follows from Example 9.3.4.11, Lemma 9.3.4.18, and Lemma 9.3.4.19. $\square$

0665 **Proposition 9.3.4.23.** *Let $\kappa \leq \lambda$ be regular cardinals, where λ is uncountable, and let $\mathcal{C}$ be an ∞ -category which is locally λ -small. Let $\widehat{\mathcal{C}} \subseteq \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$ be the full subcategory spanned by those functors $\mathcal{F}$ which satisfy the following condition:*

- (*) *There exists a full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ such that $\mathcal{F}|_{\mathcal{C}_0^{\text{op}}}$ is κ -flat, $\mathcal{F}$ is left Kan extended from $\mathcal{C}_0^{\text{op}}$, and $\mathcal{C}_0$ is essentially λ -small.*

Then the covariant Yoneda embedding

$$h_{\bullet} : \mathcal{C} \rightarrow \widehat{\mathcal{C}} \subseteq \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$$

exhibits $\widehat{\mathcal{C}}$ as an $\text{Ind}_{\kappa}^{\lambda}$ -completion of $\mathcal{C}$.

Proof. Using Proposition 8.4.5.8, we can identify $\text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ with the smallest full subcategory of $\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$ which contains all representable functors and is closed under λ -small κ -filtered colimits. For every full subcategory $\mathcal{C}_0$ of $\mathcal{C}$, the inclusion functor $\iota : \mathcal{C}_0 \hookrightarrow \mathcal{C}$ induces a functor

$$\text{Ind}_{\kappa}^{\lambda}(\iota) : \text{Ind}_{\kappa}^{\lambda}(\mathcal{C}_0) \rightarrow \text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$$

which is given (under the preceding identification) by left Kan extension along ι (Remark 9.3.3.10). Using Theorem 9.3.4.14, we see that a functor $\mathcal{F} : \mathcal{C}^{\text{op}} \rightarrow \mathcal{S}_{<\lambda}$ is contained in $\widehat{\mathcal{C}}$ if and only if it belongs to the essential image of $\text{Ind}_{\kappa}^{\lambda}(\iota)$ for some full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ which is essentially λ -small. This follows from Proposition 9.3.3.12, since the collection of such subcategories comprise a λ -filtered diagram having colimit $\mathcal{C}$. $\square$

Under some additional set-theoretic assumptions, condition (*) of Proposition 9.3.4.23 can be simplified.

0666 **Corollary 9.3.4.24.** *Let $\kappa \triangleleft \lambda$ be regular cardinals, where λ is uncountable, and let $\mathcal{C}$ be an ∞ -category which is locally λ -small. Let $\widehat{\mathcal{C}} \subseteq \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$ be the full subcategory spanned by those κ -flat functors $\mathcal{F}$ satisfying the following condition:*

- (*)' *The functor $\mathcal{F}$ is left Kan extended from $\mathcal{C}_0^{\text{op}}$, for some essentially small full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$.*

Then the covariant Yoneda embedding

$$h_{\bullet} : \mathcal{C} \rightarrow \widehat{\mathcal{C}} \subseteq \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$$

exhibits $\widehat{\mathcal{C}}$ as an $\text{Ind}_{\kappa}^{\lambda}$ -completion of $\mathcal{C}$.

Proof. As in the proof of Proposition 9.3.4.23, we can identify $\text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ with the smallest full subcategory of $\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$ which contains all representable functors and is closed under λ -small κ -filtered colimits. It follows from Lemma 9.3.4.18 (and Example 9.3.4.11), we see

that every functor $\mathcal{F} : \mathcal{C}^{\text{op}} \rightarrow \mathcal{S}_{<\lambda}$ which belongs to $\text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ is κ -flat. To complete the proof, it will suffice to show that every κ -flat functor $\mathcal{F} : \mathcal{C}^{\text{op}} \rightarrow \mathcal{S}_{<\lambda}$ satisfying condition $(*)'$ also satisfies condition $(*)$ of Proposition 9.3.4.23.

Using Proposition 8.6.8.3, we may assume that $\mathcal{F}$ is the contravariant transport representation of an essentially λ -small right fibration of ∞ -categories $U : \mathcal{E} \rightarrow \mathcal{C}$. Replacing U by a minimal fibration if necessary (Proposition 5.3.8.11). Similarly, we may assume that the ∞ -category $\mathcal{C}$ is minimal (Proposition 4.7.6.15). By assumption, the functor $\mathcal{F}$ is left Kan extended from a full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ which is essentially λ -small. Since $\mathcal{C}_0$ is also minimal, it is λ -small. We extend $\mathcal{C}_0$ to a transfinite sequence of λ -small full subcategories $\{\mathcal{C}_{\alpha} \subseteq \mathcal{C}\}_{0 \leq \beta \leq \kappa}$ as follows:

- Suppose that $\beta = \alpha + 1$ is a successor ordinal, and that the full subcategory $\mathcal{C}_{\alpha}$ has been defined. Let $\mathcal{E}_{\alpha} \subseteq \mathcal{E}$ be the inverse image of $\mathcal{C}_{\alpha}$. Since $\mathcal{C}_{\alpha}$ is λ -small and U is an essentially λ -small minimal fibration, the ∞ -category $\mathcal{E}_{\alpha}$ is also λ -small. Our assumption that $\mathcal{F}$ is κ -flat guarantees that the ∞ -category $\mathcal{E}$ is κ -filtered. Since $\kappa \triangleleft \lambda$, Proposition 9.1.7.14 guarantees that $\mathcal{E}_{\alpha}$ is contained in a λ -small simplicial subset $\mathcal{E}_{\alpha}^{+} \subseteq \mathcal{E}$ which is also a κ -filtered ∞ -category. We define $\mathcal{C}_{\beta}$ to be the full subcategory of $\mathcal{C}$ spanned by the objects $U(X)$, where X belongs to $\mathcal{E}_{\alpha}^{+}$.
- If β is a nonzero limit ordinal, we define $\mathcal{C}_{\beta}$ to be the union $\bigcup_{\alpha < \beta} \mathcal{C}_{\alpha}$.

We now claim that the full subcategory $\mathcal{C}_{\kappa} \subseteq \mathcal{C}$ satisfies condition $(*)$ of Proposition 9.3.4.23. By construction, it is a λ -small subcategory of $\mathcal{C}$ which contains $\mathcal{C}_0$, so that $\mathcal{F}$ is left Kan extended from $\mathcal{C}_{\kappa}^{\text{op}}$ (Proposition 7.3.8.11). It will therefore suffice to show that the functor $\mathcal{F}|_{\mathcal{C}_{\kappa}^{\text{op}}}$ is κ -flat: that is, that the ∞ -category $\mathcal{E}_{\kappa} = \mathcal{C}_{\kappa} \times_{\mathcal{C}} \mathcal{E}$ is κ -filtered. This is a special case of Corollary 9.1.5.16, since $\mathcal{E}_{\kappa}$ can be realized as the colimit of the κ -filtered diagram $\{\mathcal{E}_{\alpha}^{+}\}_{\alpha < \kappa}$ comprised of κ -filtered ∞ -categories. $\square$

Corollary 9.3.4.25. *Let κ be a small regular cardinal, let $\mathcal{C}$ be a locally small ∞ -category, 0667 and let $\widehat{\mathcal{C}} \subseteq \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$ be the full subcategory spanned by the κ -flat functors $\mathcal{F} : \mathcal{C}^{\text{op}} \rightarrow \mathcal{S}$ which are left Kan extended from an essentially small full subcategory of $\mathcal{C}$. Then the covariant Yoneda embedding*

$$h_{\bullet} : \mathcal{C} \rightarrow \widehat{\mathcal{C}} \subseteq \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$$

exhibits $\widehat{\mathcal{C}}$ as an Ind_{κ} -completion of $\mathcal{C}$.

Proof. Apply Corollary 9.3.4.24 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal. $\square$

Corollary 9.3.4.26. *Let $\mathcal{C}$ be a locally small ∞ -category, and let $\widehat{\mathcal{C}} \subseteq \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$ be the 0668 full subcategory spanned by the flat functors $\mathcal{F} : \mathcal{C}^{\text{op}} \rightarrow \mathcal{S}$ which are left Kan extended from*

an essentially small full subcategory of $\mathcal{C}$. Then the covariant Yoneda embedding

$$h_{\bullet} : \mathcal{C} \rightarrow \widehat{\mathcal{C}} \subseteq \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$$

exhibits $\widehat{\mathcal{C}}$ as an Ind-completion of $\mathcal{C}$.

Proof. Apply Corollary 9.3.4.25 in the special case $\kappa = \aleph_0$. □

9.3.5 Exact Functors

0669 We begin by reviewing some terminology.

066A **Definition 9.3.5.1.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor between categories which admit finite limits. We say that F is *left exact* if it preserves finite limits.

066B **Example 9.3.5.2.** The terminology of Definition 9.3.5.1 originates in homological algebra. Suppose that $\mathcal{C}$ and $\mathcal{D}$ are abelian categories (Definition [?]) and that $F : \mathcal{C} \rightarrow \mathcal{D}$ is an additive functor (that is, a functor which preserves direct sums). In this case, the following conditions are equivalent:

- (1) The functor F is left exact: that is, it preserves finite limits.
- (2) The functor F preserves equalizers.
- (3) The functor F preserves kernels. That is, for every exact sequence

$$0 \rightarrow X \xrightarrow{u} Y \xrightarrow{v} Z$$

in the abelian category $\mathcal{C}$, the image

$$0 \rightarrow F(X) \xrightarrow{F(u)} F(Y) \xrightarrow{F(v)} F(Z)$$

is an exact sequence in the abelian category $\mathcal{D}$.

The equivalence (1) $\Leftrightarrow$ (2) follows from Corollary 7.6.4.25 (since F is assumed to be additive). The equivalence (2) $\Leftrightarrow$ (3) follows from the observation that, for every pair of morphisms $f_0, f_1 : Y \rightrightarrows Z$, the equalizer $\text{Eq}(f_0, f_1)$ can be identified with the kernel of the morphism $(f_1 - f_0) : Y \rightarrow Z$ (see Proposition [?]).

066C **Remark 9.3.5.3.** In the situation of Example 9.3.5.2, we can replace (3) by the following *a priori* weaker condition:

(3') For every short exact sequence

$$0 \rightarrow X \xrightarrow{u} Y \xrightarrow{v} Z \rightarrow 0$$

in the abelian category $\mathcal{C}$, the sequence

$$0 \rightarrow F(X) \xrightarrow{F(u)} F(Y) \xrightarrow{F(v)} F(Z)$$

is also exact.

The implication (3) $\Rightarrow$ (3') is immediate. Conversely, suppose that $F : \mathcal{C} \rightarrow \mathcal{D}$ is an additive functor which satisfies condition (3'), and suppose we are given an exact sequence $0 \rightarrow X \xrightarrow{u} Y \xrightarrow{v} Z$ in $\mathcal{C}$; we wish to show that the sequence $0 \rightarrow F(X) \xrightarrow{F(u)} F(Y) \xrightarrow{F(v)} F(Z)$ is exact in $\mathcal{D}$. Applying condition (3') to the short exact sequence

$$0 \rightarrow X \xrightarrow{u} Y \xrightarrow{q} \operatorname{coker}(u) \rightarrow 0,$$

we deduce that $F(u) : F(X) \rightarrow F(Y)$ is a monomorphism, whose image is the kernel of the map of the map $F(Y) \rightarrow F(\operatorname{coker}(u))$. To show that this agrees with the kernel of $F(v)$, it will suffice to show that v induces a monomorphism $F(\operatorname{coker}(u)) \rightarrow F(Z)$ in the abelian category $\mathcal{D}$. This follows by applying condition (3') to the short exact sequence

$$0 \rightarrow \operatorname{coker}(u) \rightarrow Z \rightarrow \operatorname{coker}(v) \rightarrow 0.$$

Variant 9.3.5.4. Let $\mathcal{C}$ and $\mathcal{D}$ be categories which admit finite colimits. We say that a 066D functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is *right exact* if it preserves finite colimits: that is, if the opposite functor $F^{\operatorname{op}} : \mathcal{C}^{\operatorname{op}} \rightarrow \mathcal{D}^{\operatorname{op}}$ is left exact. When F is an additive functor between abelian categories, this condition can be restated as follows:

(*) For every exact sequence

$$X \xrightarrow{u} Y \xrightarrow{v} Z \rightarrow$$

in the abelian category $\mathcal{C}$, the sequence

$$F(X) \xrightarrow{F(u)} F(Y) \xrightarrow{F(v)} F(Z) \rightarrow 0$$

is exact in the abelian category $\mathcal{D}$.

Moreover, it suffices to verify condition (*) in the special case where u is an monomorphism (Remark 9.3.5.3).

In this section, we study an ∞ -categorical counterpart of Definition 9.3.5.1.

066E **Definition 9.3.5.5.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor between ∞ -categories. We say that F is *left exact* if, for every left fibration $\tilde{\mathcal{D}} \rightarrow \mathcal{D}$ where the ∞ -category $\tilde{\mathcal{D}}$ is cofiltered, the ∞ -category $\tilde{\mathcal{C}} = \mathcal{C} \times_{\mathcal{D}} \tilde{\mathcal{D}}$ is also cofiltered.

066F **Variant 9.3.5.6.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor between ∞ -categories. We say that F is *right exact* if, for every right fibration $\tilde{\mathcal{D}} \rightarrow \mathcal{D}$ where the ∞ -category $\tilde{\mathcal{D}}$ is filtered, the ∞ -category $\tilde{\mathcal{C}} = \mathcal{C} \times_{\mathcal{D}} \tilde{\mathcal{D}}$ is also filtered. Equivalently, F is right exact if the opposite functor $F^{\text{op}} : \mathcal{C}^{\text{op}} \rightarrow \mathcal{D}^{\text{op}}$ is left exact.

066G **Notation 9.3.5.7.** Let $\mathcal{C}$ and $\mathcal{D}$ be ∞ -categories. We let $\text{Fun}^{\text{lex}}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by the left exact functors $F : \mathcal{C} \rightarrow \mathcal{D}$, and we let $\text{Fun}^{\text{rex}}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by the right exact functors $F : \mathcal{C} \rightarrow \mathcal{D}$.

066H **Theorem 9.3.5.8.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Then:

- (1) If the functor F is right exact (in the sense of Definition 9.3.5.5), then it preserves finite colimits.
- (2) If the ∞ -category $\mathcal{C}$ admits finite colimits and F preserves finite colimits, then F is right exact.

We will give a proof of Theorem 9.3.5.8 at the end of this section.

066J **Corollary 9.3.5.9.** Let $\mathcal{C}$ and $\mathcal{D}$ be categories which admit finite limits. Then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is left exact (in the sense of Definition 9.3.5.1) if and only if the functor of ∞ -categories $N_{\bullet}(F) : N_{\bullet}(\mathcal{C}) \rightarrow N_{\bullet}(\mathcal{D})$ is left exact (in the sense of Definition 9.3.5.5).

It will be useful to consider an infinitary version of Definition 9.3.5.5.

066K **Definition 9.3.5.10.** Let κ be a regular cardinal and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. We say that F is κ -left exact if, for every left fibration $\tilde{\mathcal{D}} \rightarrow \mathcal{D}$ where the ∞ -category $\tilde{\mathcal{D}}$ is κ -cofiltered, the ∞ -category $\mathcal{C} \times_{\mathcal{D}} \tilde{\mathcal{D}}$ is also κ -cofiltered (see Definition 9.1.1.4). We say that F is κ -right exact if the opposite functor $F^{\text{op}} : \mathcal{C}^{\text{op}} \rightarrow \mathcal{D}^{\text{op}}$ is κ -left exact. We let $\text{Fun}^{\kappa\text{-lex}}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which are κ -left exact, and $\text{Fun}^{\kappa\text{-rex}}(\mathcal{C}, \mathcal{D})$ the full subcategory spanned by those functors which are κ -right exact.

066L **Remark 9.3.5.11.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Then F is left exact (in the sense of Definition 9.3.5.5) if and only if it is $\aleph_0$ -left exact (in the sense of Definition 9.3.5.10).

066M **Remark 9.3.5.12** (Monotonicity). Let κ be a regular cardinal and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a κ -left exact functor of ∞ -categories. Then F is also κ' -left exact, for any regular cardinal $\kappa' \leq \kappa$ (see Remark 9.1.1.10).

Remark 9.3.5.13 (Composition). Let $F : \mathcal{C} \rightarrow \mathcal{D}$ and $G : \mathcal{D} \rightarrow \mathcal{E}$ be functors of ∞ -categories and let κ be a regular cardinal. If F and G are κ -left exact, then the composition $(G \circ F) : \mathcal{C} \rightarrow \mathcal{E}$ is also κ -left exact. 066N

Example 9.3.5.14 (Morita Equivalence). Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a Morita equivalence of ∞ -categories (see Definition 8.5.6.1). Then F is κ -left exact for every regular cardinal κ . To prove this, choose a left fibration $\tilde{\mathcal{D}} \rightarrow \mathcal{D}$, where the ∞ -category $\tilde{\mathcal{D}}$ is κ -cofiltered; we wish to show that the ∞ -category $\tilde{\mathcal{C}} = \mathcal{C} \times_{\mathcal{D}} \tilde{\mathcal{D}}$ is also κ -cofiltered. This follows from Remark 9.1.1.15, since the projection map $\tilde{F} : \tilde{\mathcal{C}} \rightarrow \tilde{\mathcal{D}}$ is also a Morita equivalence (Corollary 8.5.6.15). 066P

Theorem 9.3.5.15. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. For every regular cardinal κ , the following conditions are equivalent: 066Q

(1 $_{\kappa}$) The functor F is κ -left exact.

(2 $_{\kappa}$) For every object $D \in \mathcal{D}$, the ∞ -category $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$ is κ -cofiltered.

Proof. For each object $D \in \mathcal{D}$, the ∞ -category $\mathcal{D}_{D/}$ has an initial object (Proposition 4.6.7.23), and is therefore κ -cofiltered (Example 9.1.1.6). Consequently, if F is κ -left exact, then the ∞ -category $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$ is also κ -cofiltered. We now prove the converse. Assume that, for each object $D \in \mathcal{D}$, the ∞ -category $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$ is κ -cofiltered. Let $U : \tilde{\mathcal{D}} \rightarrow \mathcal{D}$ be a left fibration, where $\tilde{\mathcal{D}}$ is κ -cofiltered; we wish to show that the fiber product $\tilde{\mathcal{C}} = \mathcal{C} \times_{\mathcal{D}} \tilde{\mathcal{D}}$ is also κ -cofiltered. Applying Example 7.4.5.6, we deduce that $\tilde{\mathcal{C}}$ can be realized as the colimit of a diagram

$$\mathcal{F} : \tilde{\mathcal{D}}^{\text{op}} \rightarrow \mathcal{QC} \quad X \mapsto \{X\} \tilde{\times}_{\mathcal{D}} \mathcal{C}.$$

For each object $X \in \tilde{\mathcal{D}}$, the ∞ -category $\mathcal{F}(X)$ is equivalent to $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{U(X)/}$ (Corollary 4.6.4.20), and is therefore κ -cofiltered. Since $\tilde{\mathcal{D}}^{\text{op}}$ is κ -filtered, Proposition 9.1.5.18 implies that $\tilde{\mathcal{C}}$ is also κ -cofiltered. $\square$

Remark 9.3.5.16 (Exactness and Flatness). Let κ be a regular cardinal and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Using the classification of left fibrations (see Corollary 5.6.0.6), we see that the following conditions are equivalent: 066R

(a) The functor F is κ -left exact (Definition 9.3.5.10).

(b) For every uncountable regular cardinal λ and every κ -flat functor $G : \mathcal{D} \rightarrow \mathcal{S}_{<\lambda}$ (Definition 9.3.4.7), the composite functor

$$\mathcal{C} \xrightarrow{F} \mathcal{D} \xrightarrow{G} \mathcal{S}_{<\lambda}$$

is also κ -flat.

Moreover, if the ∞ -category $\mathcal{D}$ is locally λ_0 -small (for some uncountable regular cardinal λ_0), then it suffices to verify condition (b) in the special case where $\lambda = \lambda_0$ and $G : \mathcal{D} \rightarrow \mathcal{S}_{<\lambda}$ is a corepresentable functor (Theorem 9.3.5.15).

066S Corollary 9.3.5.17. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a left exact functor of ∞ -categories. Then F is right cofinal.*

Proof. For every object $D \in \mathcal{D}$, Theorem 9.3.5.15 guarantees that the ∞ -category $\tilde{\mathcal{C}} = \mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$ is cofiltered. In particular, $\tilde{\mathcal{C}}$ is weakly contractible (Proposition 9.1.1.17). Allowing the object D to vary, we conclude that F is right cofinal (Theorem 7.2.3.1). $\square$

066T Corollary 9.3.5.18. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories which admits a left adjoint. Then F is κ -left exact for every regular cardinal κ .*

Proof. For every object $D \in \mathcal{D}$, our assumption guarantees the ∞ -category $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$ has an initial object (given by $F(D)$; see Corollary 6.2.6.2). In particular, $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$ is κ -cofiltered (Example 9.1.1.6). Allowing D to vary, we conclude that F is κ -left exact (Theorem 9.3.5.15). $\square$

For sufficiently large κ , we have the following converse of Corollary 9.3.5.18:

066U Corollary 9.3.5.19. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories and let κ be a regular cardinal. Assume that $\mathcal{C}$ is essentially κ -small, that $\mathcal{D}$ is locally κ -small, and that $\mathcal{C}$ is idempotent-complete. Then F admits a left adjoint $\mathcal{D} \rightarrow \mathcal{C}$ if and only if it is κ -left exact.*

Proof. Assume that F is κ -left exact; we will show that it admits a left adjoint (the converse is a special case of Corollary 9.3.5.18). By virtue of Corollary 6.2.6.2, it will suffice to show that for each object $D \in \mathcal{D}$, the ∞ -category $\tilde{\mathcal{C}} = \mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$ has an initial object. Our assumption that F is κ -left exact guarantees that $\tilde{\mathcal{C}}$ is κ -cofiltered (Theorem 9.3.5.15), and our assumption that $\mathcal{C}$ is idempotent-complete guarantees that $\tilde{\mathcal{C}}$ is also idempotent-complete (Corollary 8.5.4.24). It will therefore suffice to show that the ∞ -category $\tilde{\mathcal{C}}$ is essentially κ -small (Proposition 9.1.8.11). The ∞ -category $\mathcal{C}$ is essentially κ -small by assumption, and the assumption that $\mathcal{D}$ is locally κ -small guarantees that projection map $U : \tilde{\mathcal{C}} \rightarrow \mathcal{C}$ is an essentially κ -small left fibration (Corollary 5.6.7.7). The desired result now follows from Corollary 4.7.9.12. $\square$

066V Warning 9.3.5.20. In the formulation of Corollary 9.3.5.19, the assumption that $\mathcal{C}$ is idempotent-complete cannot be omitted. For example, suppose that $F : \mathcal{C} \rightarrow \mathcal{D}$ is a functor which exhibits $\mathcal{D}$ as an idempotent-completion of $\mathcal{C}$. Then F is κ -left exact for every regular cardinal κ (Example 9.3.5.14). However, F admits a left adjoint only if it is an equivalence of ∞ -categories: that is, only if the ∞ -category $\mathcal{C}$ is idempotent-complete.

Corollary 9.3.5.21. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, let κ be a regular cardinal, 066W and let $G : K \rightarrow \mathcal{C}$ be a κ -small diagram. If F is κ -left exact, then the induced map of slice ∞ -categories $F_{/G} : \mathcal{C}_{/G} \rightarrow \mathcal{D}_{/(F \circ G)}$ is also κ -left exact.*

Proof. By virtue of Theorem 9.3.5.15, it will suffice to show that for each object $\tilde{D} \in \mathcal{D}_{/(F \circ G)}$, the ∞ -category

$$\mathcal{E} = \mathcal{C}_{/G} \times_{\mathcal{D}_{/F \circ G}} (\mathcal{D}_{/F \circ G})_{\tilde{D}/}$$

is κ -cofiltered. Let D denote the image of $\tilde{D}$ in $\mathcal{D}$, and set $\tilde{\mathcal{C}} = \mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$. Then $\tilde{D}$ determines a lift of G to a diagram $\tilde{G} : K \rightarrow \tilde{\mathcal{C}}$, and $\mathcal{E}$ can be identified with the slice ∞ -category $\tilde{\mathcal{C}}_{/\tilde{G}}$. By Proposition 9.1.1.16, it will suffice to show that the ∞ -category $\tilde{\mathcal{C}}$ is κ -cofiltered, which follows from our assumption that F is κ -left exact (Theorem 9.3.5.15). $\square$

Theorem 9.3.5.8 is a special case of the following:

Theorem 9.3.5.22. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories and let κ be a regular 066X cardinal. Then:*

- (1) *If the functor F is κ -left exact, then it preserves all κ -small limits which exist in $\mathcal{C}$*
- (2) *If the ∞ -category $\mathcal{C}$ is κ -complete and F is κ -continuous, then F is κ -left exact.*

Proof. We first prove (1). Assume that F is κ -left exact; we wish to show that it preserves κ -small limits. Equivalently, we wish to show that if $G : K \rightarrow \mathcal{C}$ is a κ -small diagram, then the functor $F_{/G} : \mathcal{C}_{/G} \rightarrow \mathcal{D}_{/(F \circ G)}$ preserves final objects. It follows from Corollary 9.3.5.21 that the functor $F_{/G}$ is also κ -left exact. In particular, it is right cofinal (Corollary 9.3.5.17), and therefore preserves final objects by virtue of Corollary 7.2.1.9.

We now prove (2). Assume that $\mathcal{C}$ is κ -complete and that F is κ -continuous; we wish to show that F is κ -left exact. By virtue of Theorem 9.3.5.15, it will suffice to show that for every object $D \in \mathcal{D}$, the ∞ -category $\tilde{\mathcal{C}} = \mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/}$ is κ -cofiltered. Fix a κ -small simplicial set K and a diagram $\tilde{G} : K \rightarrow \tilde{\mathcal{C}}$; we wish to show that $\tilde{G}$ can be extended to the cone $K^\triangleleft$. Let us identify $\tilde{G}$ with a pair (G, D') , where $G : K \rightarrow \mathcal{C}$ is a diagram in $\mathcal{C}$ and D' is an object of the ∞ -category $\mathcal{D}_{/(F \circ G)}$ lying over D . Since $\mathcal{C}$ is κ -complete, we can extend G to a limit diagram $\overline{G} : K^\triangleleft \rightarrow \mathcal{C}$. Our assumption that F is κ -continuous guarantees that $F \circ \overline{G}$ is a limit diagram in $\mathcal{D}$: that is, the restriction functor $\mathcal{D}_{/(F \circ \overline{G})} \rightarrow \mathcal{D}_{/(F \circ G)}$ is a trivial Kan fibration. In particular, we can lift D' to an object $\overline{D}' \in \mathcal{D}_{/(F \circ \overline{G})}$. The pair $(\overline{G}, \overline{D}')$ can then determine an extension of $\tilde{G}$ to a diagram $K^\triangleleft \rightarrow \tilde{\mathcal{C}}$. $\square$

Corollary 9.3.5.23. *Let κ and λ be regular cardinals, where λ is uncountable, and let 066Y $F : \mathcal{C} \rightarrow \mathcal{S}_{<\lambda}$ be a functor of ∞ -categories. Each of the following conditions implies the next:*

- (1) *The functor F is κ -left exact.*

(2) *The functor F is κ -flat.*

(3) *The functor F preserves all κ -small limits which exist in $\mathcal{C}$.*

If $\mathcal{C}$ is κ -complete, then all three conditions are equivalent.

Proof. The implication (1) $\Rightarrow$ (2) follows from Remark 9.3.5.16 and the implication (2) $\Rightarrow$ (3) is Corollary 9.3.4.21. If $\mathcal{C}$ is κ -complete, then the implication (3) $\Rightarrow$ (1) is a special case of Theorem 9.3.5.22. $\square$

066Z **Warning 9.3.5.24.** Let $F : \mathcal{C} \rightarrow \mathcal{S}$ be a functor of ∞ -categories. It follows from Corollary 9.3.5.23 that if F is left exact, then it is flat. Moreover, the converse holds if $\mathcal{C}$ admits finite limits. Beware that the converse does not hold in general. For example, let R be an associative ring, let $\mathcal{E}$ be (the nerve of) the category of free left R -modules of finite rank, and let

$$F : \mathcal{E}^{\text{op}} \rightarrow \mathbf{N}_{\bullet}(\text{Set}) \subseteq \mathcal{S} \quad F(M) = \text{Hom}_R(M, R)$$

be the functor represented by R . Then F is a flat functor. Using Remark 9.3.5.16, we see that F is left exact if and only if, for every set S , the functor

$$F^S : \mathcal{E}^{\text{op}} \rightarrow \mathbf{N}_{\bullet}(\text{Set}) \subseteq \mathcal{S} \quad F(M) = \text{Hom}_R(M, R^S)$$

is also flat. By virtue of Example 9.3.4.3, this is equivalent to the requirement that R^S is a flat left R -module. This condition is satisfied only when the ring R is *right coherent*: that is, every finitely generated right ideal $I \subseteq R$ is finitely presented as a right R -module. See Theorem 2.1 of [1].

0670 **Corollary 9.3.5.25.** *Let $\kappa \leq \lambda$ be regular cardinals, where λ is uncountable. Let $\mathcal{C}$ be an ∞ -category which is κ -cocomplete and essentially λ -small. Then the covariant Yoneda embedding*

$$h_{\bullet} : \mathcal{C} \rightarrow \text{Fun}^{\kappa\text{-lex}}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$$

exhibits $\text{Fun}^{\kappa\text{-lex}}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\lambda})$ as an $\text{Ind}_{\kappa}^{\lambda}$ -completion of $\mathcal{C}$.

Proof. Combine Theorem 9.3.4.14 with Corollary 9.3.5.23. $\square$

0671 **Corollary 9.3.5.26.** *Let κ be a small regular cardinal and let $\mathcal{C}$ be an ∞ -category which is κ -cocomplete and essentially small. Then the covariant Yoneda embedding*

$$h_{\bullet} : \mathcal{C} \rightarrow \text{Fun}^{\kappa\text{-lex}}(\mathcal{C}^{\text{op}}, \mathcal{S})$$

exhibits $\text{Fun}^{\kappa\text{-lex}}(\mathcal{C}^{\text{op}}, \mathcal{S})$ as an Ind_{κ} -completion of $\mathcal{C}$.

Proof. Apply Corollary 9.3.5.25 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal. $\square$

Corollary 9.3.5.27. *Let $\mathcal{C}$ be an essentially small ∞ -category which admits finite colimits. 0672 Then the covariant Yoneda embedding*

$$h_{\bullet} : \mathcal{C} \rightarrow \mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$$

exhibits $\mathrm{Fun}^{\mathrm{lex}}(\mathcal{C}^{\mathrm{op}}, \mathcal{S})$ as an Ind-completion of $\mathcal{C}$.

Proof. Apply Corollary 9.3.5.26 in the special case $\kappa = \aleph_0$. □

9.3.6 Transitivity of Ind-Completion

We now study the dependence of the construction $\mathcal{C} \mapsto \mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ on the cardinals κ and λ . 068U

Remark 9.3.6.1. Let $\mathcal{C}$ be an ∞ -category, let $\kappa \leq \lambda$ be regular cardinals, and let $h : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ 068V be a functor which exhibits $\widehat{\mathcal{C}}$ as an $\mathrm{Ind}_{\kappa}^{\lambda}$ -completion of $\mathcal{C}$ (Variant 9.3.1.7). Suppose we are given regular cardinals κ' and λ' satisfying $\kappa \leq \kappa' \leq \lambda' \leq \lambda$, and let $\widehat{\mathcal{C}}_0$ be the smallest full subcategory of $\widehat{\mathcal{C}}$ which contains the image of h and is closed under λ' -small κ' -filtered colimits. It follows from Proposition 9.3.2.3 that the functor $h : \mathcal{C} \rightarrow \widehat{\mathcal{C}}_0$ exhibits $\widehat{\mathcal{C}}_0$ as an $\mathrm{Ind}_{\kappa'}^{\lambda'}$ -completion of $\mathcal{C}$. Stated more informally, we can identify $\mathrm{Ind}_{\kappa'}^{\lambda'}(\mathcal{C})$ with the full subcategory of $\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ generated by $\mathcal{C}$ under λ' -small κ' -filtered colimits.

Construction 9.3.6.2. Let $\kappa \leq \lambda \leq \mu$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category, and 068W let us abuse notation by identifying $\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ with a full subcategory of $\mathrm{Ind}_{\kappa}^{\mu}(\mathcal{C})$ (Remark 9.3.6.1). We let

$$T : \mathrm{Ind}_{\lambda}^{\mu}(\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})) \rightarrow \mathrm{Ind}_{\kappa}^{\mu}(\mathcal{C})$$

denote the $\mathrm{Ind}_{\lambda}^{\mu}$ -extension of the inclusion functor $\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C}) \hookrightarrow \mathrm{Ind}_{\kappa}^{\mu}(\mathcal{C})$ (see Definition 9.3.1.12). We will refer to T as the *transitivity functor*.

Proposition 9.3.6.3. *Let $\mathcal{C}$ be an ∞ -category. For every triple of regular cardinals $\kappa \leq$ 068X $\lambda \leq \mu$, the transitivity functor $T : \mathrm{Ind}_{\lambda}^{\mu}(\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})) \rightarrow \mathrm{Ind}_{\kappa}^{\mu}(\mathcal{C})$ is fully faithful.*

Proof. By virtue of Proposition 9.3.2.1, it will suffice to show that every object of $\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ is (λ, μ) -compact when viewed as an object of $\mathrm{Ind}_{\kappa}^{\mu}(\mathcal{C})$. This follows from Proposition 9.3.2.1. □

Under some additional assumptions, we have the following stronger result:

Theorem 9.3.6.4. *Let $\mathcal{C}$ be an ∞ -category. For every triple of regular cardinals $\kappa \trianglelefteq \lambda \trianglelefteq \mu$, 068Y the transitivity functor $T : \mathrm{Ind}_{\lambda}^{\mu}(\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})) \rightarrow \mathrm{Ind}_{\kappa}^{\mu}(\mathcal{C})$ is an equivalence of ∞ -categories.*

Proof. In what follows, we will abuse notation by identifying $\mathcal{C}$ and $\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ with full subcategories of $\mathrm{Ind}_{\kappa}^{\mu}(\mathcal{C})$. By virtue of Proposition 9.3.2.3, it will suffice to show that every object $X \in \mathrm{Ind}_{\kappa}^{\mu}(\mathcal{C})$ can be realized as the colimit of a μ -small λ -filtered diagram in $\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})$.

Using Corollary 9.3.4.16, we can realize X as the colimit of a diagram $F : \mathcal{K} \rightarrow \mathcal{C}$, where $\mathcal{K}$ is a μ -small κ -filtered ∞ -category. If $\kappa = \lambda$, then $\mathcal{K}$ is λ -filtered and there is nothing to prove. Otherwise, we can use Proposition 9.1.7.20 to realize $\mathcal{K}$ as the colimit of a diagram

$$A \rightarrow \mathrm{Set}_\Delta \quad (\alpha \in A) \mapsto \mathcal{K}_\alpha,$$

where A is a μ -small λ -directed partially ordered set and each $\mathcal{K}_\alpha$ is a λ -small κ -filtered ∞ -category. For each $\alpha \in A$, let X_α be a colimit of the diagram $F|_{\mathcal{K}_\alpha}$. Since $\mathcal{K}$ is also a categorical colimit of the diagram $\{\mathcal{K}_\alpha\}_{\alpha \in A}$ (Proposition 9.1.6.1), we can promote the construction $\alpha \mapsto X_\alpha$ to a diagram $\mathbf{N}_\bullet(A) \rightarrow \mathrm{Ind}_\kappa^\lambda(\mathcal{C})$ having colimit X (see Proposition 7.5.8.12). $\square$

068Z **Warning 9.3.6.5.** In the situation of Theorem 9.3.6.4, the assumption $\lambda \leq \mu$ cannot be omitted. For example, let S be set of cardinality $\geq \mu$, let $\mathrm{Sub}_{<\kappa}(S)$ denote the nerve of the partially ordered set of all κ -small subsets of S , and define $\mathrm{Sub}_{<\lambda}(S)$ and $\mathrm{Sub}_{<\mu}(S)$ similarly. Assume that $\kappa \leq \lambda$ and $\kappa \leq \mu$ (this condition is always satisfied, for example, if $\kappa = \aleph_0$; see Example 9.1.7.10). Then Example 9.3.2.11 supplies equivalences

$$\mathrm{Ind}_\kappa^\lambda(\mathrm{Sub}_{<\kappa}(S)) \xrightarrow{\sim} \mathrm{Sub}_{<\lambda}(S) \quad \mathrm{Ind}_\kappa^\mu(\mathrm{Sub}_{<\kappa}(S)) \xrightarrow{\sim} \mathrm{Sub}_{<\mu}(S).$$

In this case, the conclusion of Theorem 9.3.6.4 is satisfied if and only if the comparison map $\mathrm{Ind}_\lambda^\mu(\mathrm{Sub}_{<\lambda}(S)) \hookrightarrow \mathrm{Sub}_{<\mu}(S)$ is an equivalence, which is equivalent to the requirement $\lambda \leq \mu$ (Example 9.3.2.11).

0690 **Warning 9.3.6.6.** In the situation of Theorem 9.3.6.4, the assumption $\kappa \leq \lambda$ cannot be omitted. For example, suppose that μ satisfies $\kappa \leq \mu$ and $\lambda \leq \mu$ (these condition are satisfied, for example, if $\mu = (2^\lambda)^+$; see Corollary 9.1.7.9). If S is a set of cardinality $\geq \mu$, then Example 9.3.2.11 supplies equivalences

$$\mathrm{Ind}_\kappa^\mu(\mathrm{Sub}_{<\kappa}(S)) \xrightarrow{\sim} \mathrm{Sub}_{<\mu}(S) \quad \mathrm{Ind}_\lambda^\mu(\mathrm{Sub}_{<\lambda}(S)) \xrightarrow{\sim} \mathrm{Sub}_{<\mu}(S).$$

In this case, the conclusion of Theorem 9.3.6.4 is satisfied if and only if the comparison map $\iota : \mathrm{Ind}_\kappa^\lambda(\mathrm{Sub}_{<\kappa}(S)) \hookrightarrow \mathrm{Sub}_{<\lambda}(S)$ induces an equivalence of Ind_λ^μ -completions. If this condition is satisfied, then ι itself is an equivalence (see Exercise 9.4.1.20), so that $\kappa \leq \lambda$ (Example 9.3.2.11).

Let us now record some consequences of Theorem 9.3.6.4.

0691 **Corollary 9.3.6.7.** *Let $\mathcal{C}$ be an ∞ -category and let $\kappa \leq \lambda \leq \mu$ be regular cardinals, where λ is uncountable. Then an object $X \in \mathrm{Ind}_\kappa^\mu(\mathcal{C})$ is (λ, μ) -compact if and only if it belongs to the full subcategory $\mathrm{Ind}_\kappa^\lambda(\mathcal{C}) \subseteq \mathrm{Ind}_\kappa^\mu(\mathcal{C})$ (see Remark 9.3.6.1).*

Proof. Combine Corollary 9.4.1.21 with Theorem 9.3.6.4. $\square$

Corollary 9.3.6.8. *Let $\mathcal{C}$ be an ∞ -category and let $\kappa \leq \lambda$ be small regular cardinals, where λ is uncountable. Then an object $X \in \mathrm{Ind}_\kappa(\mathcal{C})$ is λ -compact if and only if it belongs to the full subcategory $\mathrm{Ind}_\kappa^\lambda(\mathcal{C}) \subseteq \mathrm{Ind}_\kappa(\mathcal{C})$.* 0692

Proof. Apply Corollary 9.3.6.7 in the special case where $\mu = \Omega$ is strongly inaccessible. $\square$

Warning 9.3.6.9. Corollary 9.3.6.8 is not quite true in the case $\kappa = \lambda = \aleph_0$: in this case, 0693
an object of $\mathrm{Ind}(\mathcal{C})$ is compact if and only if it can be obtained as a *retract* of an object of $\mathrm{Ind}_\kappa^\lambda(\mathcal{C}) \simeq \mathcal{C}$ (see Proposition 9.4.1.19).

Corollary 9.3.6.10. *Let $\kappa \leq \lambda \leq \mu$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category. If $\mathcal{C}$ is 0694
 (κ, λ) -cocomplete, then the ∞ -category $\mathrm{Ind}_\lambda^\mu(\mathcal{C})$ is (κ, μ) -cocomplete. The converse holds if $\mathcal{C}$ is idempotent-complete.*

Proof. Choose a functor $g : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ which exhibits $\widehat{\mathcal{C}}$ as an $\mathrm{Ind}_\kappa^\lambda$ -completion of $\mathcal{C}$. Assume first that $\mathcal{C}$ is (κ, λ) -cocomplete, so that g admits a left adjoint $f : \widehat{\mathcal{C}} \rightarrow \mathcal{C}$. Then the functor $F = \mathrm{Ind}_\lambda^\mu(f)$ is left adjoint to $G = \mathrm{Ind}_\lambda^\mu(g)$ (Exercise 9.3.3.11). Since g is fully faithful, the functor G is also fully faithful (Corollary 9.3.2.2), and therefore induces an equivalence from $\mathrm{Ind}_\lambda^\mu(\mathcal{C})$ to a reflective subcategory of $\mathrm{Ind}_\lambda^\mu(\widehat{\mathcal{C}})$ (Remark 6.3.3.4). By virtue of Corollary 7.1.4.24, it will suffice to show that the ∞ -category $\mathrm{Ind}_\lambda^\mu(\widehat{\mathcal{C}})$ is (κ, μ) -cocomplete. This follows from the equivalence $\mathrm{Ind}_\lambda^\mu(\widehat{\mathcal{C}}) \simeq \mathrm{Ind}_\kappa^\mu(\mathcal{C})$ supplied by Theorem 9.3.6.4.

We now prove the converse. Assume that $\mathrm{Ind}_\lambda^\mu(\mathcal{C})$ is (κ, μ) -cocomplete. If $\mathcal{C}$ is idempotent-complete, then it can be identified with the full subcategory of $\mathrm{Ind}_\lambda^\mu(\mathcal{C})$ spanned by the (λ, μ) -compact objects (Corollary 9.4.1.21). This full subcategory is closed under all λ -small colimits which exist in $\mathrm{Ind}_\lambda^\mu(\mathcal{C})$ (Proposition 9.2.5.23), and therefore admits λ -small κ -filtered colimits. $\square$

Corollary 9.3.6.11. *Let $\kappa \leq \lambda \leq \mu$ be regular cardinals. Let $\mathcal{C}$ be an ∞ -category which is 0695
 (κ, λ) -cocomplete, let $\mathcal{D}$ be an ∞ -category which is (κ, μ) -cocomplete, and let $h : \mathcal{C} \rightarrow \mathcal{D}$ be a functor with Ind_λ^μ -extension $H : \mathrm{Ind}_\lambda^\mu(\mathcal{C}) \rightarrow \mathcal{D}$. The following conditions are equivalent:*

- (1) *The functor H is (κ, μ) -finitary.*
- (2) *The functor H is (κ, λ) -finitary*
- (3) *The functor h is (κ, λ) -finitary.*

Proof. The implication (1) $\Rightarrow$ (2) is trivial (Remark 9.2.2.8) and the implication (2) $\Rightarrow$ (3) follows from the observation that the functor $\mathcal{C} \rightarrow \mathrm{Ind}_\lambda^\mu(\mathcal{C})$ is (κ, λ) -finitary (Proposition 9.3.2.16). We will complete the proof by showing that (3) implies (1) (the implication (2) $\Rightarrow$ (1) is a special case of Proposition 9.2.2.29, but we will not need this). As in the proof of Corollary 9.3.6.10, fix a functor $g : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ which exhibits $\widehat{\mathcal{C}}$ as an $\mathrm{Ind}_\kappa^\lambda$ -completion of $\mathcal{C}$ and set $G = \mathrm{Ind}_\lambda^\mu(g)$, so that g and G admit left adjoints f and $F = \mathrm{Ind}_\lambda^\mu(f)$, respectively.

Suppose we are given a diagram $Q : \mathcal{K} \rightarrow \mathrm{Ind}_\lambda^\mu(\mathcal{C})$, where $\mathcal{K}$ is a μ -small κ -filtered ∞ -category; we wish to show that the colimit of Q is preserved by the functor H . Since G is fully faithful, Q is isomorphic to the composite $F \circ \widehat{Q}$, where $\widehat{Q} = G \circ Q$. The functor F is a left adjoint, and therefore preserves all colimits (Corollary 7.1.4.23). It will therefore suffice to show that the colimit of $\widehat{Q}$ is preserved by the functor $(H \circ F) : \mathrm{Ind}_\lambda^\mu(\widehat{\mathcal{C}}) \rightarrow \mathcal{D}$.

Using Theorem 9.3.6.4, we can identify $\mathrm{Ind}_\lambda^\mu(\widehat{\mathcal{C}})$ with an Ind_κ^μ -completion of $\mathcal{C}$. Let $H' : \mathrm{Ind}_\lambda^\mu(\widehat{\mathcal{C}}) \rightarrow \mathcal{D}$ be the Ind_κ^μ -extension of the functor h . We will complete the proof by showing that H' is isomorphic to $H \circ F$. Since both H' and $H \circ F$ are (λ, μ) -finitary, it will suffice to show that they have the same restriction to $\widehat{\mathcal{C}}$: that is, that $H'|_{\widehat{\mathcal{C}}}$ is isomorphic to the composition $\widehat{\mathcal{C}} \xrightarrow{f} \mathcal{C} \xrightarrow{h} \mathcal{D}$. By construction, they become isomorphic after precomposition with the functor g . It will therefore suffice to show that $h \circ f$ is (κ, λ) -finitary, which follows from assumption (3). $\square$

06GB **Corollary 9.3.6.12.** *Let $\kappa \leq \lambda \leq \mu$ be regular cardinals, let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, and suppose that $\mathcal{C}$ and $\mathcal{D}$ are (κ, λ) -cocomplete. Then F is (κ, λ) -finitary if and only if the functor $\mathrm{Ind}_\lambda^\mu(F) : \mathrm{Ind}_\lambda^\mu(\mathcal{C}) \rightarrow \mathrm{Ind}_\lambda^\mu(\mathcal{D})$ is (κ, μ) -finitary.*

06GC **Example 9.3.6.13.** Let $\kappa \leq \lambda \leq \mu$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete. Then an object $C \in \mathcal{C}$ is (κ, λ) -compact if and only if its image in $\mathrm{Ind}_\lambda^\mu(\mathcal{C})$ is (κ, μ) -compact. This follows by applying Corollary 9.3.6.11 to the functor $h^C : \mathcal{C} \rightarrow \mathcal{S}_{<\nu}$ corepresented by C (for some sufficiently large cardinal ν).

9.3.7 Final Objects of Ind-Completions

06GD The primary goal of this section is to establish the following characterization of filtered ∞ -categories:

06GE **Theorem 9.3.7.1.** *Let $\mathcal{C}$ be a small ∞ -category. Then $\mathcal{C}$ is filtered if and only if the Ind-completion $\mathrm{Ind}(\mathcal{C})$ has a final object.*

Theorem 9.3.7.1 asserts in particular that if $\mathcal{C}$ is a small filtered ∞ -category, then the ∞ -category $\mathrm{Ind}(\mathcal{C})$ has a final object. In fact, we can be more precise: the final object of $\mathrm{Ind}(\mathcal{C})$ can be characterized as a colimit of the tautological map $\mathcal{C} \rightarrow \mathrm{Ind}(\mathcal{C})$. This is a special case of the following:

06GF **Proposition 9.3.7.2.** *Let $\kappa \leq \lambda$ be regular cardinals, where λ is uncountable. Let $\mathcal{C}$ be an ∞ -category which is κ -filtered and essentially λ -small, and let $F : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ be a functor which exhibits $\widehat{\mathcal{C}}$ as an $\mathrm{Ind}_\kappa^\lambda$ -completion of $\mathcal{C}$. Then the colimit $X = \varinjlim (F)$ is final object of $\widehat{\mathcal{C}}$. In particular, the ∞ -category $\widehat{\mathcal{C}}$ has a final object.*

Proof. We wish to show that, for every object $Y \in \widehat{\mathcal{C}}$, the morphism space $\mathrm{Hom}_{\widehat{\mathcal{C}}}(Y, X)$ is contractible. Using Proposition 7.4.1.18, we see that the collection of objects $Y \in \widehat{\mathcal{C}}$

which satisfy this condition is closed under colimits; in particular, it is closed under λ -small κ -filtered colimits. We may therefore assume without loss of generality that $Y = F(C)$ for some object $C \in \mathcal{C}$. Fix a regular cardinal $\mu \geq \lambda$ such that $\widehat{\mathcal{C}}$ is locally μ -small, so that $F(C)$ corepresents a functor

$$G : \widehat{\mathcal{C}} \rightarrow \mathcal{S}_{<\mu} \quad Z \mapsto \mathrm{Hom}_{\widehat{\mathcal{C}}}(F(C), Z).$$

We wish to show that $G(X)$ is contractible. Since $F(C)$ is a (κ, λ) -compact object of $\widehat{\mathcal{C}}$ (Proposition 9.3.2.3), we can identify $G(X)$ with the colimit of the diagram $(G \circ F) : \mathcal{C} \rightarrow \mathcal{S}_{<\mu}$. Since F is fully faithful, we can identify $G \circ F$ with the corepresentable functor $\mathrm{Hom}_{\mathcal{C}}(C, \bullet)$, so that $\varinjlim (G \circ F)$ is contractible by virtue of Example 7.4.3.7. $\square$

Remark 9.3.7.3. In the situation of Proposition 9.3.7.2, we can identify $\widehat{\mathcal{C}}$ with the full subcategory of $\mathrm{Fun}(\mathcal{C}^{\mathrm{op}}, \mathcal{S}_{<\lambda})$ spanned by the κ -flat functors (Theorem 9.3.4.14). Consequently, to show that $\widehat{\mathcal{C}}$ has a final object, it suffices to show that the constant functor $\mathcal{F} : \mathcal{C}^{\mathrm{op}} \rightarrow \{\Delta^0\} \rightarrow \mathcal{S}_{<\lambda}$ is κ -flat. This is a reformulation of the hypothesis that $\mathcal{C}$ is κ -filtered, since $\mathcal{F}$ is the contravariant transport representation for the right fibration $\mathrm{id} : \mathcal{C} \rightarrow \mathcal{C}$. 06GG

Proposition 9.3.7.4. *Let $\mathcal{C}$ be an ∞ -category and let $\kappa \leq \lambda$ be regular cardinals. Each of the following conditions implies the previous:* 06GH

- (1) *The ∞ -category $\mathcal{C}$ is κ -filtered.*
- (2) *The ∞ -category $\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ is κ -filtered.*
- (3) *The ∞ -category $\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ is λ -filtered.*
- (4) *The ∞ -category $\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ has a final object.*

If λ is uncountable and $\mathcal{C}$ is essentially λ -small, then all four conditions are equivalent.

Proof. The implication (4) $\Rightarrow$ (3) follows from Example 9.1.1.6 and the implication (3) $\Rightarrow$ (2) from Remark 9.1.1.10. If λ is uncountable and $\mathcal{C}$ is essentially λ -small, then the implication (4) $\Rightarrow$ (1) follows from Proposition 9.3.7.2. We will complete the proof by showing that (2) implies (1). In what follows, let us abuse notation by identifying $\mathcal{C}$ with a full subcategory of $\widehat{\mathcal{C}} = \mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})$. Assume that $\widehat{\mathcal{C}}$ is κ -filtered; we will show that $\mathcal{C}$ is κ -filtered. Fix a κ -small diagram $F : K \rightarrow \mathcal{C}$; we wish to show that there exists a natural transformation from F to the constant diagram $\underline{X} : K \rightarrow \mathcal{C}$, for some $X \in \mathcal{C}$. Note that each object $C \in \mathcal{C}$ is (κ, λ) -compact when viewed as an object of $\widehat{\mathcal{C}}$ (Proposition 9.3.2.3). Applying Proposition 9.2.8.7, we conclude that F is (κ, λ) -compact when viewed as an object of the diagram

∞ -category $\mathrm{Fun}(K, \widehat{\mathcal{C}})$. Fix a regular cardinal $\mu \geq \lambda$ such that $\mathrm{Fun}(K, \widehat{\mathcal{C}})$ is locally μ -small, so that the functor

$$Q : \widehat{\mathcal{C}} \rightarrow \mathcal{S}_{<\mu} \quad Q(X) = \mathrm{Hom}_{\mathrm{Fun}(K, \widehat{\mathcal{C}})}(F, \underline{X})$$

is (κ, λ) -finitary. Since $\widehat{\mathcal{C}}$ is κ -filtered, there exists a natural transformation from F to a constant diagram in $\widehat{\mathcal{C}}$: that is, the Kan complex $Q(X)$ is nonempty for some $X \in \widehat{\mathcal{C}}$. Invoking the universal property of $\widehat{\mathcal{C}}$, we see that the restriction functor $\mathrm{Fun}^{(\kappa, \lambda)\text{-fin}}(\widehat{\mathcal{C}}, \mathcal{S}_{<\mu}) \rightarrow \mathrm{Fun}(\mathcal{C}, \mathcal{S}_{<\mu})$ is an equivalence of ∞ -categories. It follows that $Q(X)$ must be also be nonempty for some $X \in \mathcal{C}$, as desired. $\square$

06GJ **Corollary 9.3.7.5.** *Let $\mathcal{C}$ be an essentially small ∞ -category and let κ be a small regular cardinal. Then $\mathcal{C}$ is κ -filtered if and only if the ∞ -category $\mathrm{Ind}_{\kappa}(\mathcal{C})$ has a final object.*

Proof. Apply Proposition 9.3.7.4 in the case where $\lambda = \Omega$ is a strongly inaccessible cardinal. $\square$

Proof of Theorem 9.3.7.1. Apply Corollary 9.3.7.5 in the special case $\kappa = \aleph_0$. $\square$

06GK **Corollary 9.3.7.6.** *Let $\kappa \trianglelefteq \lambda$ be regular cardinals. For every ∞ -category $\mathcal{C}$, the following conditions are equivalent:*

- (1) *The ∞ -category $\mathcal{C}$ is κ -filtered.*
- (2) *The ∞ -category $\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ is κ -filtered.*
- (3) *The ∞ -category $\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ is λ -filtered.*

Proof. The implications (3) $\Rightarrow$ (2) $\Rightarrow$ (1) follow from Proposition 9.3.7.4 (and do not require the assumption that $\kappa \trianglelefteq \lambda$). We will show that (1) implies (3). Choose a regular cardinal μ satisfying $\lambda \trianglelefteq \mu$ such that $\mathcal{C}$ is essentially μ -small. If $\mathcal{C}$ is κ -filtered, then Proposition 9.3.7.4 implies that the ∞ -category $\mathrm{Ind}_{\kappa}^{\mu}(\mathcal{C})$ has a final object. Theorem 9.3.6.4 guarantees that $\mathrm{Ind}_{\kappa}^{\mu}(\mathcal{C})$ can be viewed as an $\mathrm{Ind}_{\lambda}^{\mu}$ -completion of $\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})$. Applying Proposition 9.3.7.4 again, we conclude that $\mathrm{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ is λ -filtered. $\square$

06GL **Warning 9.3.7.7.** In the formulation of Corollary 9.3.7.6, the assumption $\kappa \trianglelefteq \lambda$ cannot be omitted. See Exercise 9.3.7.8.

06GM **Exercise 9.3.7.8.** Let $\kappa \leq \lambda$ be regular cardinals, let S be a λ -small set, and let $\mathrm{Sub}_{<\kappa}(S)$ be (the nerve of) the partially ordered set of κ -small subsets of S . Show that the following conditions are equivalent:

- (1) The ∞ -category $\mathrm{Ind}_{\kappa}^{\lambda}(\mathrm{Sub}_{<\kappa}(S))$ is λ -filtered.

- (2) The ∞ -category $\mathrm{Ind}_\kappa^\lambda(\mathrm{Sub}_{<\kappa}(S))$ has a final object.
- (3) There exists a λ -small collection of κ -small subsets $\{S_\alpha \subseteq S\}$ such that every κ -small subset of S is contained in some S_α .

In particular, if these conditions are satisfied for every λ -small set S , then $\kappa \leq \lambda$.

We now prove a companion to Theorem 9.3.7.1, which characterizes right cofinal functors between (small) filtered ∞ -categories.

Theorem 9.3.7.9. *Let $\mathcal{C}$ and $\mathcal{D}$ be small filtered ∞ -categories. Then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is right cofinal if and only if the induced functor $\mathrm{Ind}(F) : \mathrm{Ind}(\mathcal{C}) \rightarrow \mathrm{Ind}(\mathcal{D})$ preserves final objects.* 06GN

The proof of Theorem 9.3.7.9 will require some preliminaries.

Lemma 9.3.7.10. *Let $\kappa \leq \lambda$ be regular cardinals and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. If the induced functor $\mathrm{Ind}_\kappa^\lambda(F) : \mathrm{Ind}_\kappa^\lambda(\mathcal{C}) \rightarrow \mathrm{Ind}_\kappa^\lambda(\mathcal{D})$ is right cofinal, then F is right cofinal.* 06GP

Proof. Let us abuse notation by identifying $\mathcal{C}$ and $\mathcal{D}$ with full subcategories of the ∞ -categories $\widehat{\mathcal{C}} = \mathrm{Ind}_\kappa^\lambda(\mathcal{C})$ and $\widehat{\mathcal{D}} = \mathrm{Ind}_\kappa^\lambda(\mathcal{D})$, respectively. Setting $\widehat{F} = \mathrm{Ind}_\kappa^\lambda(F)$, we can assume without loss of generality that $F = \widehat{F}|_{\mathcal{C}}$. Fix a regular cardinal $\mu \geq \lambda$ such that $\widehat{\mathcal{C}}$ and $\widehat{\mathcal{D}}$ are μ -small. By virtue of Proposition 7.4.3.11, it will suffice to show that for every functor $G : \mathcal{D} \rightarrow \mathcal{S}_{<\mu}$ which is corepresentable by an object $D \in \mathcal{D}$, the composite functor $(G \circ F) : \mathcal{C} \rightarrow \mathcal{S}_{<\mu}$ has a contractible colimit. Let $\widehat{G} : \widehat{\mathcal{D}} \rightarrow \mathcal{S}_{<\mu}$ be the functor corepresented by D . Since D is (κ, λ) -compact when viewed as an object of $\widehat{\mathcal{D}}$, the functor $\widehat{G}$ is (κ, λ) -finitary. It follows that the composite functor $(\widehat{G} \circ \widehat{F}) : \widehat{\mathcal{C}} \rightarrow \mathcal{S}_{<\mu}$ is also (κ, λ) -finitary, and is therefore left Kan extended from $\mathcal{C}$ (Remark 9.3.1.13). Applying Corollary 7.3.8.3, we are reduced to showing that the colimit $\varinjlim (\widehat{G} \circ \widehat{F})$ is a contractible Kan complex, which follows from our assumption that $\widehat{F}$ is right cofinal (Proposition 7.4.3.11). $\square$

Proposition 9.3.7.11. *Let $\kappa \leq \lambda$ be regular cardinals, where λ is uncountable. Let $\mathcal{C}$ and $\mathcal{D}$ be λ -small κ -filtered ∞ -categories and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor. The following conditions are equivalent:* 06GQ

- (1) *The functor F is right cofinal.*
- (2) *The functor $\mathrm{Ind}_\kappa^\lambda(F) : \mathrm{Ind}_\kappa^\lambda(\mathcal{C}) \rightarrow \mathrm{Ind}_\kappa^\lambda(\mathcal{D})$ is right cofinal.*
- (3) *The functor $\mathrm{Ind}_\kappa^\lambda(F)$ preserves final objects.*

Proof. Since $\mathcal{C}$ is λ -small and κ -filtered, the ∞ -category $\mathrm{Ind}_\kappa^\lambda(\mathcal{C})$ has a final object (Proposition 9.3.7.2). The equivalence (2) $\Leftrightarrow$ (3) now follows from Corollary 7.2.1.9, and the implication (2) $\Rightarrow$ (1) is a special case of Lemma 9.3.7.10. We complete the proof by showing that (1) $\Rightarrow$ (3). Assume that F is right cofinal and let X be a final object of $\mathrm{Ind}_\kappa^\lambda(\mathcal{C})$; we wish to show that $\widehat{F} = \mathrm{Ind}_\kappa^\lambda(F)$ carries X to a final object of $\mathrm{Ind}_\kappa^\lambda(\mathcal{D})$. Using Proposition 9.3.7.2, we can identify X with a colimit of the tautological map $h : \mathcal{C} \rightarrow \mathrm{Ind}_\kappa^\lambda(\mathcal{C})$. Since the functor $\widehat{F}$ is (κ, λ) -finitary, it follows that $\widehat{F}(X)$ is a colimit of the diagram $\widehat{F} \circ h$, which is isomorphic to the composition $\mathcal{C} \xrightarrow{F} \mathcal{D} \rightarrow \mathrm{Ind}_\kappa^\lambda(\mathcal{D})$. If F is right cofinal, then this is also a colimit of the tautological map $\mathcal{D} \rightarrow \mathrm{Ind}_\kappa^\lambda(\mathcal{D})$ (Corollary 7.2.2.3), and is therefore a final object of $\mathrm{Ind}_\kappa^\lambda(\mathcal{D})$ (Proposition 9.3.7.2). $\square$

06GR Corollary 9.3.7.12. *Let κ be a small regular cardinal and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor between small κ -filtered ∞ -categories. Then F is right cofinal if and only if the functor $\mathrm{Ind}_\kappa(F) : \mathrm{Ind}_\kappa(\mathcal{C}) \rightarrow \mathrm{Ind}_\kappa(\mathcal{D})$ preserves final objects.*

Proof. Apply Proposition 9.3.7.11 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal. $\square$

Proof of Theorem 9.3.7.9. Apply Corollary 9.3.7.12 in the special case $\kappa = \aleph_0$. $\square$

06GS Corollary 9.3.7.13. *Let $\kappa \leq \lambda$ be regular cardinals and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor between κ -filtered ∞ -categories. Then F is right cofinal if and only if the induced functor $\mathrm{Ind}_\kappa^\lambda(F) : \mathrm{Ind}_\kappa^\lambda(\mathcal{C}) \rightarrow \mathrm{Ind}_\kappa^\lambda(\mathcal{D})$ is right cofinal.*

Proof. Assume that F is right cofinal; we will show that $\widehat{F} = \mathrm{Ind}_\kappa^\lambda(F)$ is right cofinal (the converse is a special case of Lemma 9.3.7.10, and requires weaker assumptions). Choose a regular cardinal μ satisfying $\lambda \leq \mu$ such that $\mathcal{C}$ and $\mathcal{D}$ are essentially μ -small. By virtue of Lemma 9.3.7.10, it will suffice to show that $\mathrm{Ind}_\lambda^\mu(\widehat{F})$ is right cofinal. This follows from Proposition 9.3.7.11, because we can identify $\mathrm{Ind}_\lambda^\mu(\widehat{F})$ with the functor $\mathrm{Ind}_\kappa^\mu(F) : \mathrm{Ind}_\kappa^\mu(\mathcal{C}) \rightarrow \mathrm{Ind}_\kappa^\mu(\mathcal{D})$ (see Theorem 9.3.6.4 and Proposition 9.2.2.29). $\square$

9.4 Compact Generation and Accessibility

06GT In the development of category theory, it is often important to be mindful of some dichotomy between “large” and “small”. This is for two reasons:

- (a) Many of the categories which appear naturally can be fit into a specific mold: their objects are sets equipped with some additional structure, and their morphisms are functions which preserve the structure. Categories of this form (such as the categories of sets, groups, and partially ordered sets) tend not to be small.

- (b) From a theoretical perspective, it is technically convenient to work with categories which admit small colimits (or at least some large class of colimits). Such categories are rarely small: a small category which admits small coproducts is equivalent to a partially ordered set (Proposition 7.1.2.15).

These motivations are connected with one another. Large categories $\mathcal{C}$ which arise in mathematical practice tend to be large in a very specific way: they are obtained from a small subcategory by (freely) adjoining certain colimits. This observation was articulated more precisely in the work of Makkai-Paré ([44]).

Definition 9.4.0.1 (Makkai-Paré). A category $\mathcal{C}$ is *accessible* if there exists a small regular cardinal κ satisfying the following conditions:

- (1 $_{\kappa}$) The category $\mathcal{C}$ admits small κ -filtered colimits.
- (2 $_{\kappa}$) Every object of $\mathcal{C}$ can be realized as a small κ -filtered colimit of κ -compact objects of $\mathcal{C}$.
- (3 $_{\kappa}$) The full subcategory of κ -compact objects $\mathcal{C}_{<\kappa} \subseteq \mathcal{C}$ is essentially small.

Our goal in this section is to study the ∞ -categorical counterpart of Definition 9.4.0.1. Fix a small regular cardinal κ . We will say that an ∞ -category $\mathcal{C}$ is *κ -compactly generated* if it satisfies conditions (1 $_{\kappa}$) and (2 $_{\kappa}$) of Definition 9.4.0.1. In §9.4.1 we show that, if this condition is satisfied, then the ∞ -categories $\mathcal{C}$ and $\mathcal{C}_{<\kappa}$ are essentially interchangeable data. More precisely, Corollary 9.4.1.23 implies that the construction $\mathcal{C} \mapsto \mathcal{C}_{<\kappa}$ induces a bijection

$$\begin{array}{c} \{\kappa\text{-compactly generated } \infty\text{-categories } \mathcal{C}\} / \text{Equivalence} \\ \downarrow \sim \\ \{\text{Idempotent-complete } \infty\text{-categories } \mathcal{C}_0\} / \text{Equivalence}, \end{array}$$

where the inverse bijection is given by the construction $\mathcal{C}_0 \mapsto \text{Ind}_{\kappa}(\mathcal{C}_0)$ studied in §9.3.

The preceding bijection has a counterpart at the level of functors. Let $\mathcal{C}$ and $\mathcal{D}$ be κ -compactly generated ∞ -categories. We will say that a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is *κ -compact* if it is κ -finitary (that is, it preserves small κ -filtered colimits) and carries κ -compact objects of $\mathcal{C}$ to κ -compact objects of $\mathcal{D}$. In §9.4.2, we show that the restriction functor $F \mapsto F|_{\mathcal{C}_{<\kappa}}$ induces a bijection

$$\begin{array}{c} \{\kappa\text{-compact functors } F : \mathcal{C} \rightarrow \mathcal{D}\} / \text{Isomorphism} \\ \downarrow \sim \\ \{\text{Functors } F_0 : \mathcal{C}_{<\kappa} \rightarrow \mathcal{D}_{<\kappa}\} / \text{Isomorphism}, \end{array}$$

where the inverse bijection is given by the construction $F_0 \mapsto \text{Ind}_\kappa(F_0)$ (see Remark 9.4.2.10 and Example 9.4.2.11).

The bulk of this section is devoted to studying the closure properties of compact generation. Let $\mathcal{C}_-$, $\mathcal{C}_+$ and $\mathcal{C}$ be κ -compactly generated ∞ -categories, and suppose we are given κ -compact functors $F_- : \mathcal{C}_- \rightarrow \mathcal{C}$ and $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$. In §9.4.3, we show that the oriented fiber product $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ is also κ -compactly generated (moreover, this is true more generally if the functor F_+ is only assumed to be κ -finitary: see Theorem 9.4.3.2). From this, we can formally deduce several other results:

- If $\mathcal{C}$ is κ -compactly generated and X is an object of $\mathcal{C}$, then the slice ∞ -category $\mathcal{C}_{/X}$ is κ -compactly generated (Corollary 9.4.3.5)
- If $\mathcal{C}$ is κ -compactly generated and X is a κ -compact object of $\mathcal{C}$, then the coslice ∞ -category $\mathcal{C}_{X/}$ is κ -compactly generated (Corollary 9.4.3.7).
- If $\mathcal{C}$ is κ -compactly generated and K is the nerve of a finite partially ordered set (for example, a standard simplex), then the diagram ∞ -category $\text{Fun}(K, \mathcal{C})$ is also κ -compactly generated (Corollary 9.4.3.9).

The situation for homotopy fiber products is more subtle. Beware that, if $F_- : \mathcal{C}_- \rightarrow \mathcal{C}$ and $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$ are κ -compact functors between κ -compactly generated ∞ -categories, then the homotopy fiber product $\mathcal{C}_- \times_{\mathcal{C}}^h \mathcal{C}_+$ need not be κ -compactly generated: in fact, it might not contain any κ -compact objects at all (Exercise 9.4.4.1). However, we will prove in §9.4.4 that it is κ -compactly generated provided that there exists some regular cardinal $\kappa_0 < \kappa$ such that F_- and F_+ are κ_0 -finitary (for a more general statement, see Theorem 9.4.4.4). In §9.4.5, we apply this result to establish many other stability properties of the collection of κ -compactly generated ∞ -categories.

We will say that an ∞ -category $\mathcal{C}$ is κ -*accessible* if it satisfies the ∞ -categorical counterpart of Definition 9.4.0.1: that is, if it is κ -compactly generated and the full subcategory $\mathcal{C}_{<\kappa} \subseteq \mathcal{C}$ is essentially small. We will say that an ∞ -category $\mathcal{C}$ is *accessible* if it is κ -accessible for some small regular cardinal κ . In §9.4.6, we collect some basic facts about accessible ∞ -categories:

- If an ∞ -category $\mathcal{C}$ is accessible, then it is λ -accessible for arbitrarily large values of λ (Proposition 9.4.6.16). In particular, each of the full subcategories $\mathcal{C}_{<\lambda}$ is essentially small (Corollary 9.4.6.7).
- If $\mathcal{C}$ is accessible, then every object $C \in \mathcal{C}$ is λ -compact for some λ : that is, $\mathcal{C}$ can be realized as the directed union $\bigcup_{\lambda} \mathcal{C}_{<\lambda}$ (Remark 9.4.6.8). In particular, $\mathcal{C}$ is locally small.

- An essentially small ∞ -category $\mathcal{C}$ is accessible if and only if it is idempotent-complete (Proposition 9.4.6.21).

Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor between accessible ∞ -categories. We say that the functor F is *accessible* if it preserves small κ -filtered colimits for some small regular cardinal κ (Definition 9.4.7.1). In §9.4.7 we show that, if this condition is satisfied, then we can choose a small regular cardinal $\lambda \geq \kappa$ such that $\mathcal{C}$ and $\mathcal{D}$ are λ -accessible and F is λ -compact: that is, F can be realized as the Ind_λ -extension of its restriction $F_{<\lambda} : \mathcal{C}_{<\lambda} \rightarrow \mathcal{D}_{<\lambda}$ (Proposition 9.4.7.9). In §9.4.8, we combine this observation with the results of §9.4.5 to show that the collection of accessible ∞ -categories has robust closure properties. For example, if $\{\mathcal{C}_\alpha\}$ is a small diagram of accessible ∞ -categories in which the transition maps are accessible functors, then the limit $\varprojlim(\mathcal{C}_\alpha)$ is also accessible (Corollary 9.4.8.11).

9.4.1 Compactly Generated ∞ -Categories

In this section, we study ∞ -categories $\mathcal{C}$ which contain “enough” compact objects. 0673

Definition 9.4.1.1. Let $\mathcal{C}$ be an ∞ -category. We say that $\mathcal{C}$ is *compactly generated* if it 0674
satisfies the following conditions:

- (a) The ∞ -category $\mathcal{C}$ admits small filtered colimits.
- (b) Every object $C \in \mathcal{C}$ can be realized as the colimit of a small filtered diagram $\{C_\alpha\}$,
where each C_α is a compact object of $\mathcal{C}$.

Example 9.4.1.2. Let $\mathcal{S}$ denote the ∞ -category of spaces (Construction 5.5.1.1). Then $\mathcal{S}$ 06GV
is compactly generated. It admits small colimits (Corollary 7.4.3.3 and every object $X \in \mathcal{S}$
can be realized as a small filtered colimit of essentially finite Kan complexes (Proposition
9.3.2.17), which are compact by virtue of Corollary 9.2.6.5.

Example 9.4.1.3. Let $\mathcal{QC}$ denote the ∞ -category of (small) ∞ -categories (Construction 06GW
5.5.4.1). Then $\mathcal{QC}$ is compactly generated. It admits small colimits (Corollary 7.4.5.3),
and every object $\mathcal{C} \in \mathcal{QC}$ can be realized as a small filtered colimits of essentially finite
 ∞ -categories (Proposition 9.3.2.21), which are compact by virtue of Proposition 9.2.7.9.

Example 9.4.1.4. Every Kan complex X is compactly generated when viewed as an 0675
 ∞ -category: see Examples 9.2.5.5 and 7.3.9.5.

Definition 9.4.1.5. Let κ be a small regular cardinal and let $\mathcal{C}$ be an ∞ -category. We say 0676
that $\mathcal{C}$ is κ -*compactly generated* if it satisfies the following conditions:

- (a_κ) The ∞ -category $\mathcal{C}$ admits small κ -filtered colimits.

(b_κ) Every object $C \in \mathcal{C}$ can be realized as the colimit of a small κ -filtered diagram $\{C_\alpha\}$, where each C_α is a κ -compact object of $\mathcal{C}$.

0677 **Example 9.4.1.6.** An ∞ -category $\mathcal{C}$ is compactly generated (in the sense of Definition 9.4.1.1) if and only if it is $\aleph_0$ -compactly generated (in the sense of Definition 9.4.1.5). See Example 9.2.5.8.

0678 **Variant 9.4.1.7.** Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category. We say that $\mathcal{C}$ is (κ, λ) -compactly generated if it satisfies the following conditions:

$(a_{\kappa, \lambda})$ The ∞ -category $\mathcal{C}$ is (κ, λ) -cocomplete: that is, it admits λ -small κ -filtered colimits.

$(b_{\kappa, \lambda})$ Every object $C \in \mathcal{C}$ can be realized as the colimit of a λ -small κ -filtered diagram $\{C_\alpha\}$, where each C_α is a (κ, λ) -compact object of $\mathcal{C}$.

0679 **Remark 9.4.1.8.** Following the convention of Remark 4.7.0.5, a regular cardinal κ is small if it satisfies $\kappa < \Omega$, for some fixed strongly inaccessible cardinal Ω . In this case, an ∞ -category $\mathcal{C}$ is κ -compactly generated (in the sense of Definition 9.4.1.5) if and only if it is (κ, Ω) -compactly generated (in the sense of Variant 9.4.1.7). In particular, $\mathcal{C}$ is compactly generated if and only if it is $(\aleph_0, \Omega)$ -compactly generated. See Remark 9.2.5.14.

067A **Example 9.4.1.9.** Let κ be an uncountable regular cardinal. An ∞ -category $\mathcal{C}$ is (κ, κ) -compactly generated if and only if it is idempotent-complete (see Example 9.2.5.15). If $\kappa = \aleph_0$, every ∞ -category is (κ, κ) -compactly generated.

06GX **Remark 9.4.1.10.** Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category. Then $\mathcal{C}$ is (κ, λ) -compactly generated if and only if it is (κ, λ) -cocomplete and satisfies the following stronger version of condition $(b_{\kappa, \lambda})$:

$(b_{\kappa, \lambda}^+)$ Every object $C \in \mathcal{C}$ can be realized as the colimit of a diagram

$$\mathbf{N}_\bullet(A) \rightarrow \mathcal{C} \quad (\alpha \in A) \mapsto C_\alpha,$$

where $(A, \leq)$ is a λ -small κ -directed partially ordered set and each C_α is a (κ, λ) -compact object of $\mathcal{C}$.

This follows from Theorem 9.1.8.7 (for the case $\kappa \triangleleft \lambda$) and Example 9.4.1.9 (for the case $\kappa = \lambda$).

067B **Proposition 9.4.1.11.** Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category. The following conditions are equivalent:

(1) The ∞ -category $\mathcal{C}$ is (κ, λ) -compactly generated.

- (2) *There exists a functor of ∞ -categories $\mathcal{C}' \rightarrow \mathcal{C}$ which exhibits $\mathcal{C}$ as an $\mathrm{Ind}_\kappa^\lambda$ -completion of $\mathcal{C}'$ (Variant 9.3.1.7).*
- (3) *There exists a full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ for which the inclusion functor $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ exhibits $\mathcal{C}$ as an $\mathrm{Ind}_\kappa^\lambda$ -completion of $\mathcal{C}_0$.*

Moreover, if these conditions are satisfied, then we can take $\mathcal{C}_0$ to be the full subcategory of $\mathcal{C}$ spanned by the (κ, λ) -compact objects.

Proof. The implication (3) $\Rightarrow$ (2) is immediate, and the implication (2) $\Rightarrow$ (1) follows from Proposition 9.3.2.3 and Corollary 9.3.4.24. To complete the proof, assume that $\mathcal{C}$ is (κ, λ) -compactly generated, and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be the full subcategory spanned by the (κ, λ) -compact objects. Applying the criterion of Proposition 9.3.2.3, we conclude that the inclusion functor $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ exhibits $\mathcal{C}$ as an $\mathrm{Ind}_\kappa^\lambda$ -completion of $\mathcal{C}_0$. $\square$

Example 9.4.1.12. Let $\kappa \trianglelefteq \lambda$ be regular cardinals, where λ is uncountable. Then the ∞ -categories $\mathcal{S}_{<\lambda}$ and $\mathcal{QC}_{<\lambda}$ are (κ, λ) -compactly generated. This follows by combining Proposition 9.4.1.11 with Variants 9.3.2.18 and 9.3.2.22, respectively (together with Remark 9.3.2.20 in the special case $\kappa = \aleph_0$). 06GY

Corollary 9.4.1.13. *Let κ be a small regular cardinal and let $\mathcal{C}$ be an ∞ -category. The following conditions are equivalent:* 067C

- (1) *The ∞ -category $\mathcal{C}$ is κ -compactly generated.*
- (2) *There exists a functor of ∞ -categories $\mathcal{C}' \rightarrow \mathcal{C}$ which exhibits $\mathcal{C}$ as an Ind_κ -completion of $\mathcal{C}'$ (Definition 9.3.1.4).*
- (3) *There exists a full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ for which the inclusion functor $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ exhibits $\mathcal{C}$ as an Ind_κ -completion of $\mathcal{C}_0$.*

Moreover, if these conditions are satisfied, then we can take $\mathcal{C}_0 = \mathcal{C}_{<\kappa}$ to be the full subcategory of $\mathcal{C}$ spanned by the κ -compact objects.

Proof. Apply Proposition 9.4.1.11 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal (Remark 9.4.1.8). $\square$

Corollary 9.4.1.14. *Let $\mathcal{C}$ be an ∞ -category. The following conditions are equivalent:* 067D

- (1) *The ∞ -category $\mathcal{C}$ is compactly generated.*
- (2) *There exists a functor of ∞ -categories $\mathcal{C}' \rightarrow \mathcal{C}$ which exhibits $\mathcal{C}$ as an Ind -completion of $\mathcal{C}'$ (Definition 9.3.1.1).*

- (3) *There exists a full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ for which the inclusion functor $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ exhibits $\mathcal{C}$ as an Ind-completion of $\mathcal{C}_0$.*

Moreover, if these conditions are satisfied, then we can take $\mathcal{C}_0 = \mathcal{C}_{<\aleph_0}$ to be the full subcategory of $\mathcal{C}$ spanned by the compact objects.

Proof. Apply Corollary 9.4.1.13 in the special case $\kappa = \aleph_0$ (see Example 9.4.1.6). $\square$

067E Remark 9.4.1.15. Let $\kappa \leq \lambda$ be regular cardinals, and let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete. To show that $\mathcal{C}$ is (κ, λ) -compactly generated, it suffices to verify the following (which is *a priori* weaker than condition $(b_{\kappa, \lambda})$ of Variant 9.4.1.7):

- $(b_{\kappa, \lambda}^-)$ Let $\mathcal{C}_0 \subseteq \mathcal{C}$ be the full subcategory spanned by the (κ, λ) -compact objects. Then $\mathcal{C}_0$ generated $\mathcal{C}$ under λ -small κ -filtered colimits. That is, if $\mathcal{C}' \subseteq \mathcal{C}$ is a replete full subcategory which contains $\mathcal{C}_0$ and is closed under λ -small κ -filtered colimits, then $\mathcal{C}' = \mathcal{C}$.

In this case, the recognition principle of Proposition 9.3.2.3 guarantees that $\mathcal{C}$ is an $\text{Ind}_{\kappa}^{\lambda}$ -completion of the full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$.

06GZ Remark 9.4.1.16 (Colimits of Compact Objects). Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -compactly generated, and let $\mathcal{C}_0 \subseteq \mathcal{D}$ be the full subcategory spanned by the (κ, λ) -compact objects. Then the inclusion functor $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ creates κ -small colimits (Definition 7.1.4.18). In other words, a κ -small diagram $K \rightarrow \mathcal{C}_0$ admits a colimit in the ∞ -category $\mathcal{C}_0$ if and only if it admits a colimit in the ∞ -category $\mathcal{C}$, in which case the colimits are the same (see Propositions 9.2.5.23 and 9.3.2.16).

06H0 Corollary 9.4.1.17. *Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -compactly generated, and let $\mathcal{D}$ be an ∞ -category which is (κ, λ) -cocomplete. Then a functor $G : \mathcal{D} \rightarrow \mathcal{C}$ is (κ, λ) -finitary if and only if it satisfies the following condition:*

- $(*)$ *For every (κ, λ) -compact object $C \in \mathcal{C}$, the composition*

$$\mathcal{D} \xrightarrow{G} \mathcal{C} \xrightarrow{\text{Hom}_{\mathcal{C}}(C, \bullet)} \mathcal{S}_{<\mu}$$

is (κ, λ) -finitary.

Here $\mu \geq \lambda$ denotes any regular cardinal for which $\mathcal{C}$ is locally μ -small.

Proof. Let $\mathcal{C}_{<\kappa} \subseteq \mathcal{C}$ be the full subcategory of $\mathcal{C}$ spanned by the (κ, λ) -compact objects. It follows from Propositions 9.4.1.11 and 8.4.5.8, that the restricted Yoneda embedding

$$h_{\bullet} : \mathcal{C} \rightarrow \text{Fun}(\mathcal{C}_{<\kappa}^{\text{op}}, \mathcal{S}_{<\mu}) \quad X \mapsto \text{Hom}_{\mathcal{C}}(\bullet, X)$$

is an equivalence from $\mathcal{C}$ to the smallest full subcategory of $\text{Fun}(\mathcal{C}_{<\kappa}^{\text{op}}, \mathcal{S}_{<\mu})$ which contains all representable functors and is closed under λ -small κ -filtered colimits. It follows that G is (κ, λ) -finitary if and only if the composition $h_{\bullet} \circ G$ is (κ, λ) -finitary. The equivalence of this condition with $(*)$ follows from the observation that μ -small colimits in $\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\mu})$ are computed levelwise (Proposition 7.1.8.3). $\square$

Beware that, in the setting of Proposition 9.4.1.11, the subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ is generally not unique. However, it is unique up to Morita equivalence, by virtue of the following result (compare with Propositions 9.2.6.7 and 9.2.7.12):

Lemma 9.4.1.18. *Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete, and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a full subcategory. Assume that $\mathcal{C}_0$ generates $\mathcal{C}$ under λ -small κ -filtered colimits (in the sense of Remark 9.4.1.15). Then every (κ, λ) -compact object $C \in \mathcal{C}$ is a retract of an object of $\mathcal{C}_0$.* 067F

Proof. Let $\mathcal{C}' \subseteq \mathcal{C}$ be the full subcategory spanned by those objects D which satisfy the following condition:

$(*)$ Every morphism $f : C \rightarrow D$ factors (up to homotopy) through an object of $\mathcal{C}_0$.

Then $\mathcal{C}'$ contains $\mathcal{C}_0$, and our assumption that C is (κ, λ) -compact guarantees that $\mathcal{C}'$ is closed under the formation of λ -small κ -filtered colimits. Since $\mathcal{C}_0$ generates $\mathcal{C}$ under λ -small κ -filtered colimits, we must have $\mathcal{C}' = \mathcal{C}$. In particular, $\mathcal{C}'$ contains the object C , so the identity morphism $\text{id}_C : C \rightarrow C$ factors through an object of $\mathcal{C}_0$. $\square$

Proposition 9.4.1.19. *Let $\kappa \leq \lambda$ be regular cardinals, where λ is uncountable, let $h : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ be a functor of ∞ -categories which exhibits $\widehat{\mathcal{C}}$ as an $\text{Ind}_{\kappa}^{\lambda}$ -completion of $\mathcal{C}$, and let $\widehat{\mathcal{C}}_0 \subseteq \widehat{\mathcal{C}}$ be the full subcategory spanned by the (κ, λ) -compact objects. Then h exhibits $\widehat{\mathcal{C}}_0$ as an idempotent-completion of $\mathcal{C}$.* 067G

Proof. It follows from Proposition 9.3.2.3 that h induces an equivalence from $\mathcal{C}$ to a full subcategory of $\widehat{\mathcal{C}}_1 \subseteq \widehat{\mathcal{C}}_0$ which generates $\widehat{\mathcal{C}}$ under λ -small κ -filtered colimits. Applying Lemma 9.4.1.18, we see that every object of $\widehat{\mathcal{C}}_0$ is a retract of an object of $\widehat{\mathcal{C}}_1$. It will therefore suffice to show that $\widehat{\mathcal{C}}_0$ is idempotent-complete. This follows from Proposition 8.5.4.8, since the ∞ -category $\widehat{\mathcal{C}}$ is idempotent-complete (Proposition 9.2.1.14) and the full subcategory $\widehat{\mathcal{C}}_0$ is closed under retracts (Remark 9.2.5.18). $\square$

Exercise 9.4.1.20. Let $\kappa \leq \lambda$ be regular cardinals, where λ is uncountable, and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Show that F is a Morita equivalence if and only if $\text{Ind}_{\kappa}^{\lambda}(F) : \text{Ind}_{\kappa}^{\lambda}(\mathcal{C}) \rightarrow \text{Ind}_{\kappa}^{\lambda}(\mathcal{D})$ is an equivalence of ∞ -categories. 067H

Corollary 9.4.1.21. *Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category which is idempotent-complete. Then the tautological map $\mathcal{C} \rightarrow \text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ induces an equivalence from $\mathcal{C}$ to the full subcategory of $\text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ spanned by the (κ, λ) -compact objects.* 067J

067K **Proposition 9.4.1.22.** *Let $\kappa \leq \lambda$ be regular cardinals, where λ is uncountable. Then the construction $\mathcal{C} \mapsto \text{Ind}_\kappa^\lambda(\mathcal{C})$ induces a bijection*

$$\begin{array}{c} \{\text{Idempotent-complete } \infty\text{-categories}\}/\text{Equivalence} \\ \downarrow \sim \\ \{(\kappa, \lambda)\text{-compactly generated } \infty\text{-categories}\}/\text{Equivalence}. \end{array}$$

Proof. Surjectivity follows from Proposition 9.4.1.11, and injectivity from Proposition 9.4.1.19. $\square$

067L **Corollary 9.4.1.23.** *Let κ be a small regular cardinal. Then the construction $\mathcal{C} \mapsto \text{Ind}_\kappa(\mathcal{C})$ induces a bijection*

$$\begin{array}{c} \{\text{Idempotent-complete } \infty\text{-categories}\}/\text{Equivalence} \\ \downarrow \sim \\ \{\kappa\text{-compactly generated } \infty\text{-categories}\}/\text{Equivalence}. \end{array}$$

Proof. Apply Proposition 9.4.1.22 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal (Remark 9.4.1.8). $\square$

067M **Corollary 9.4.1.24.** *The construction $\mathcal{C} \mapsto \text{Ind}(\mathcal{C})$ induces a bijection*

$$\begin{array}{c} \{\text{Idempotent-complete } \infty\text{-categories}\}/\text{Equivalence} \\ \downarrow \sim \\ \{\text{Compactly generated } \infty\text{-categories}\}/\text{Equivalence}. \end{array}$$

Proof. Apply Corollary 9.4.1.23 in the special case $\kappa = \aleph_0$ (Example 9.4.1.6). $\square$

06H1 **Proposition 9.4.1.25.** *Let $\kappa \trianglelefteq \lambda \trianglelefteq \mu$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category. If the ∞ -category $\mathcal{C}$ is (κ, λ) -compactly generated, then the ∞ -category $\text{Ind}_\lambda^\mu(\mathcal{C})$ is (κ, μ) -compactly generated. The converse holds if $\mathcal{C}$ is idempotent-complete.*

Proof. If $\mathcal{C}$ is (κ, λ) -compactly generated, then it can be identified with $\text{Ind}_\kappa^\lambda(\mathcal{C}_0)$ for some ∞ -category $\mathcal{C}_0$ (Proposition 9.4.1.11). Applying Theorem 9.3.6.4, we conclude that $\text{Ind}_\lambda^\mu(\mathcal{C})$ is equivalent to $\text{Ind}_\kappa^\mu(\mathcal{C}_0)$, and is therefore (κ, μ) -compactly generated.

We now prove the converse. Assume that $\widehat{\mathcal{C}} = \text{Ind}_{\lambda}^{\mu}(\mathcal{C})$ is (κ, μ) -compactly generated: that is, we have an equivalence $\widehat{\mathcal{C}} \simeq \text{Ind}_{\kappa}^{\mu}(\mathcal{C}_0)$ for some other ∞ -category $\mathcal{C}_0$. If $\mathcal{C}$ is idempotent-complete, then it can be identified with the full subcategory of $\widehat{\mathcal{C}}$ spanned by the (λ, μ) -compact objects (Corollary 9.4.1.21). Using Corollary 9.3.6.8, we can identify this ∞ -category with $\text{Ind}_{\kappa}^{\lambda}(\mathcal{C}_0)$, so that $\mathcal{C}$ is (κ, λ) -compactly generated. $\square$

Corollary 9.4.1.26. *Let $\kappa \trianglelefteq \lambda \trianglelefteq \mu$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category. Then $\mathcal{C}$ is (κ, μ) -compactly generated if and only if it satisfies the following pair of conditions:* 06H2

- (1) *The ∞ -category $\mathcal{C}$ is (λ, μ) -compactly generated.*
- (2) *The full subcategory $\mathcal{C}_{<\lambda} \subseteq \mathcal{C}$ spanned by the (λ, μ) -compact objects is (κ, λ) -compactly generated.*

Proof. Suppose first that $\mathcal{C}$ is (κ, μ) -compactly generated: that is, it can be identified with the $\text{Ind}_{\kappa}^{\mu}$ -completion of some ∞ -category $\mathcal{D}$. Applying Theorem 9.3.6.4, we conclude that $\mathcal{C}$ can also be identified with the $\text{Ind}_{\lambda}^{\mu}$ -completion of the ∞ -category $\text{Ind}_{\kappa}^{\lambda}(\mathcal{D})$, and is therefore also (λ, μ) -compactly generated.

Conversely, suppose that $\mathcal{C}$ is (λ, μ) -compactly generated: that is, it can be identified with the $\text{Ind}_{\lambda}^{\mu}$ -completion of the full subcategory $\mathcal{C}_{<\lambda} \subseteq \mathcal{C}$. In this case, we wish to show that $\mathcal{C}$ is (κ, μ) -compactly generated if and only if $\mathcal{C}_{<\lambda}$ is (κ, λ) -compactly generated. Without loss of generality, we may assume that μ is uncountable (otherwise, both conditions are vacuous). In this case, the ∞ -category $\mathcal{C}$ is idempotent-complete. Since the full subcategory $\mathcal{C}_{<\lambda}$ is closed under retracts (Remark 9.2.5.18), it is also idempotent-complete (Proposition 8.5.4.8). The desired equivalence now follows by applying Proposition 9.4.1.25 to the ∞ -category $\mathcal{C}_{<\lambda}$. $\square$

9.4.2 Compact Functors

We now study functors between compactly generated ∞ -categories. 06H3

Definition 9.4.2.1. Let $\mathcal{C}$ be a compactly generated ∞ -category and let $\mathcal{D}$ be an ∞ -category which admits small filtered colimits. We say that a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is *compact* if it is finitary (Definition 9.2.2.1) and carries compact objects of $\mathcal{C}$ to compact objects of $\mathcal{D}$. We let $\text{Fun}^c(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by the compact functors from $\mathcal{C}$ to $\mathcal{D}$. 06H4

Variant 9.4.2.2. Let κ be a small regular cardinal, let $\mathcal{C}$ be a κ -compactly generated ∞ -category and let $\mathcal{D}$ be an ∞ -category which admits small κ -filtered colimits. We say that a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is κ -*compact* if it is κ -finitary (Definition 9.2.2.3) and carries κ -compact objects of $\mathcal{C}$ to κ -compact objects of $\mathcal{D}$. We let $\text{Fun}^{\kappa-c}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by the κ -compact functors from $\mathcal{C}$ to $\mathcal{D}$. 06H5

- 06H6 **Remark 9.4.2.3.** Let $\mathcal{C}$ be a compactly generated ∞ -category and let $\mathcal{D}$ be an ∞ -category which admits small filtered colimits. Then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is compact (in the sense of Definition 9.4.2.1) if and only if it is $\aleph_0$ -compact (in the sense of Variant 9.4.2.2).
- 06H7 **Variant 9.4.2.4.** Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -compactly generated, and let $\mathcal{D}$ be an ∞ -category which is (κ, λ) -cocomplete. We say that a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is (κ, λ) -compact if it is (κ, λ) -finitary (Definition 9.2.2.6) and carries (κ, λ) -compact objects of $\mathcal{C}$ to (κ, λ) -compact objects of $\mathcal{D}$. We let $\mathrm{Fun}^{(\kappa, \lambda)-c}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\mathrm{Fun}(\mathcal{C}, \mathcal{D})$ spanned by the (κ, λ) -compact functors from $\mathcal{C}$ to $\mathcal{D}$.
- 06H8 **Remark 9.4.2.5.** Following the convention of Remark 4.7.0.5, a regular cardinal κ is small if it satisfies $\kappa < \Omega$, where Ω is some fixed strongly inaccessible cardinal. In this case, a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is κ -compact (in the sense of Variant 9.4.2.2) if and only if it is (κ, Ω) -compact (in the sense of Variant 9.4.2.4).
- 06H9 **Example 9.4.2.6.** Let $\kappa \leq \lambda$ be regular cardinals and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be an equivalence of ∞ -categories. Then $\mathcal{C}$ is (κ, λ) -compactly generated if and only if $\mathcal{D}$ is (κ, λ) -compactly generated. If these conditions are satisfied, then the functor F is automatically (κ, λ) -compact. In particular, if $\mathcal{C}$ is (κ, λ) -compactly generated, then the identity functor $\mathrm{id}_{\mathcal{C}}$ is (κ, λ) -compact.
- 06HA **Example 9.4.2.7.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor between idempotent-complete ∞ -categories. Then F is (κ, κ) -compact for every regular cardinal κ . See Examples 9.2.2.16 and 9.2.5.15.
- 06HB **Example 9.4.2.8.** Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete. Then an object $C \in \mathcal{C}$ is (κ, λ) -compact (in the sense of Definition 9.2.5.12) if and only if the inclusion map $\{C\} \hookrightarrow \mathcal{C}$ is a (κ, λ) -compact functor (in the sense of Variant 9.4.2.4).
- 06HC **Example 9.4.2.9.** Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -compactly generated. For every simplicial set K , the diagram ∞ -category $\mathrm{Fun}(K, \mathcal{C})$ is (κ, λ) -cocomplete and the diagonal map $\delta : \mathcal{C} \rightarrow \mathrm{Fun}(K, \mathcal{C})$ is (κ, λ) -finitary (see Proposition 7.1.8.2). If K is κ -small, then the functor δ is (κ, λ) -compact (see Proposition 9.2.8.7).
- 06HD **Remark 9.4.2.10.** Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -compactly generated, and let $\mathcal{D}$ be an ∞ -category which is (κ, λ) -cocomplete. Then the restriction functor

$$\mathrm{Fun}^{(\kappa, \lambda)-c}(\mathcal{C}, \mathcal{D}) \rightarrow \mathrm{Fun}(\mathcal{C}_{<\kappa}, \mathcal{D}_{<\kappa}) \quad F \mapsto F|_{\mathcal{C}_{<\kappa}}$$

is an equivalence of ∞ -categories. Here $\mathcal{C}_{<\kappa}$ and $\mathcal{D}_{<\kappa}$ denote the full subcategories spanned by the (κ, λ) -compact objects of $\mathcal{C}$ and $\mathcal{D}$, respectively. See Proposition 9.4.1.11.

Example 9.4.2.11. Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ and $\mathcal{D}$ be ∞ -categories, and 06HE
 set $\widehat{\mathcal{C}} = \text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ and $\widehat{\mathcal{D}} = \text{Ind}_{\kappa}^{\lambda}(\mathcal{D})$. If $\mathcal{D}$ is idempotent-complete, then the construction
 $F \mapsto \text{Ind}_{\kappa}^{\lambda}(F)$ induces an equivalence of ∞ -categories $\text{Fun}(\mathcal{C}, \mathcal{D}) \simeq \text{Fun}^{(\kappa, \lambda)-c}(\widehat{\mathcal{C}}, \widehat{\mathcal{D}})$. More
 precisely, if $h : \mathcal{C} \rightarrow \widehat{\mathcal{C}}$ and $j : \mathcal{D} \rightarrow \widehat{\mathcal{D}}$ are functors which exhibit $\widehat{\mathcal{C}}$ and $\widehat{\mathcal{D}}$ as $\text{Ind}_{\kappa}^{\lambda}$ -completions
 of $\mathcal{C}$ and $\mathcal{D}$ (respectively), then the functors

$$\text{Fun}(\mathcal{C}, \mathcal{D}) \xrightarrow{j \circ} \text{Fun}(\mathcal{C}, \widehat{\mathcal{D}}) \xleftarrow{h \circ} \text{Fun}^{(\kappa, \lambda)-c}(\widehat{\mathcal{C}}, \widehat{\mathcal{D}})$$

are fully faithful and have the same essential image.

Example 9.4.2.12. Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which is (κ, λ) - 06HF
 compactly generated, suppose we are given a κ -small collection of functors $\{F_i : \mathcal{C} \rightarrow \mathcal{D}_i\}_{i \in I}$,
 where each of the ∞ -categories $\mathcal{D}_i$ is (κ, λ) -cocomplete. If the induced functor

$$F : \mathcal{C} \rightarrow \prod_{i \in I} \mathcal{D}_i$$

is (κ, λ) -compact, then each of the functors F_i is (κ, λ) -compact. The converse holds if the
 index set I is κ -small. See Proposition 9.2.8.4.

Remark 9.4.2.13 (Retracts). Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which 06HG
 is (κ, λ) -compactly generated, and let $\mathcal{D}$ be an ∞ -category which is (κ, λ) -cocomplete, and
 let $F : \mathcal{C} \rightarrow \mathcal{D}$ be (κ, λ) -compact functor. If $G : \mathcal{C} \rightarrow \mathcal{D}$ is a retract of F (in the ∞ -category
 $\text{Fun}(\mathcal{C}, \mathcal{D})$), then G is also (κ, λ) -compact (see Remark 9.2.5.18). In particular, if F and G
 are isomorphic, then F is (κ, λ) -compact if and only if G is (κ, λ) -compact.

Remark 9.4.2.14 (Composition). Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ and $\mathcal{D}$ be ∞ - 06HH
 categories which are (κ, λ) -compactly generated, and let $\mathcal{E}$ be an ∞ -category which is
 (κ, λ) -cocomplete. If $F : \mathcal{C} \rightarrow \mathcal{D}$ and $G : \mathcal{D} \rightarrow \mathcal{E}$ are (κ, λ) -compact functors, then the
 composition $(G \circ F) : \mathcal{C} \rightarrow \mathcal{E}$ is (κ, λ) -compact.

Notation 9.4.2.15. Let $\mathcal{QC}$ denote the ∞ -category of (small) ∞ -categories (Construction 06HJ
 5.5.4.1). For every pair of regular cardinals $\kappa \leq \lambda$, we define a subcategory $\mathcal{QC}^{\text{CG}(\kappa, \lambda)} \subseteq \mathcal{QC}$
 as follows:

- An object $\mathcal{C}$ of $\mathcal{QC}$ belongs to $\mathcal{QC}^{\text{CG}(\kappa, \lambda)}$ if and only if it is a (κ, λ) -compactly generated.
- A morphism $F : \mathcal{C} \rightarrow \mathcal{D}$ of $\mathcal{QC}$ belongs to $\mathcal{QC}^{\text{CG}(\kappa, \lambda)}$ if and only if it is a (κ, λ) -compact
 functor.

More generally, if μ is any uncountable cardinal, we let $\mathcal{QC}_{<\mu}^{\text{CG}(\kappa, \lambda)}$ denote the subcategory of
 $\mathcal{QC}_{<\mu}$ whose objects are μ -small ∞ -categories which are (κ, λ) -compactly generated, and
 whose morphisms are (κ, λ) -compact functors. In practice, we will be primarily interested
 in the case where μ is much larger than λ (so that there are plenty of examples of such
 ∞ -categories).

06HK **Remark 9.4.2.16.** Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{QC}^{\text{IC}}$ denote the full subcategory of $\mathcal{QC}$ spanned by the idempotent complete ∞ -categories. If λ is small and uncountable, then the construction $\mathcal{C} \mapsto \text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ induces an equivalence from $\mathcal{QC}^{\text{IC}}$ to the subcategory $\mathcal{QC}^{\text{CG}(\kappa, \lambda)}$ of Notation 9.4.2.15. More generally, assume that λ is uncountable and let $\mu > \lambda$ be a cardinal of exponential cofinality $\geq \lambda$, so that the construction $\mathcal{C} \mapsto \text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ carries essentially μ -small ∞ -categories to essentially μ -small ∞ -categories (see Proposition 9.3.3.7). Then the formation of $\text{Ind}_{\kappa}^{\lambda}$ -completions induces an equivalence from $\mathcal{QC}_{<\mu}^{\text{IC}}$ to the subcategory $\mathcal{QC}_{<\mu}^{\text{CG}(\kappa, \lambda)} \subseteq \mathcal{QC}_{<\mu}$. This follows from Proposition 9.4.1.22 and Remark 9.4.2.10.

06HL **Example 9.4.2.17.** Let $\kappa \leq \lambda$ be regular cardinals and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, where $\mathcal{C}$ is (κ, λ) -compactly generated and $\mathcal{D}$ is (κ, λ) -cocomplete. Suppose that F admits a right adjoint $G : \mathcal{D} \rightarrow \mathcal{C}$. Then:

- The functor F is automatically (κ, λ) -finitary (Corollary 7.1.4.23).
- If G is (κ, λ) -finitary, then F is (κ, λ) -compact (Remark 9.2.5.19).

For a partial converse, see Proposition [?]

06HM **Proposition 9.4.2.18** (Transitivity). *Let $\kappa \trianglelefteq \lambda \trianglelefteq \mu$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which is (κ, μ) -compactly generated, and let $\mathcal{D}$ be an ∞ -category which is (κ, μ) -cocomplete. Then every (κ, μ) -compact functor $F : \mathcal{C} \rightarrow \mathcal{D}$ satisfies the following pair of conditions:*

- (1) *The functor F is (λ, μ) -compact. In particular, it restricts to a functor $F_{<\lambda} : \mathcal{C}_{<\lambda} \rightarrow \mathcal{D}_{<\lambda}$, where $\mathcal{C}_{<\lambda}$ and $\mathcal{D}_{<\lambda}$ denote the full subcategories of $\mathcal{C}$ and $\mathcal{D}$ spanned by the (λ, μ) -compact objects.*
- (2) *The functor $F_{<\lambda}$ is (κ, λ) -compact.*

The converse holds if the ∞ -category $\mathcal{D}$ is (λ, μ) -compactly generated.

Proof. Assume first that F is (κ, μ) -compact. To prove (1), we must show that for every object $C \in \mathcal{C}_{<\lambda}$, the image $F(C)$ belongs to $\mathcal{D}_{<\lambda}$. Using Corollary 9.3.6.7, we can realize C as the colimit of a λ -small κ -filtered diagram $G : \mathcal{K} \rightarrow \mathcal{C}$, carrying each object of $\mathcal{K}$ to a (κ, μ) -compact object of $\mathcal{C}$. Since the functor F is (κ, μ) -finitary, it follows that $F(C)$ is a colimit of the diagram $(F \circ G) : \mathcal{K} \rightarrow \mathcal{D}$. By assumption, this diagram carries each object of $\mathcal{K}$ to an object of $\mathcal{D}$ which is (κ, μ) -compact, and therefore also (λ, μ) -compact. Since $\mathcal{K}$ is λ -small, it follows that $F(C)$ is also (λ, μ) -compact (Proposition 9.2.5.23). This completes the proof of (1). To prove (2), we observe that if $C \in \mathcal{C}$ is (κ, μ) -compact, then $F(C)$ is (κ, μ) -compact as an object of $\mathcal{D}$, and therefore also (κ, λ) -compact as an object of the subcategory $\mathcal{D}_{<\lambda}$.

We now prove the converse. Assume that $\mathcal{D}$ is (λ, μ) -compactly generated and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor satisfying conditions (1) and (2); we wish to show that F is (κ, μ) -compact. Since $\mathcal{C}$ is (λ, μ) -compactly generated (Corollary 9.4.1.26), assumption (1) guarantees that we can identify F with the Ind_λ^μ -extension of the functor $F_{<\lambda} : \mathcal{C}_{<\lambda} \rightarrow \mathcal{D}$. Assumption (2) guarantees that $F_{<\lambda}$ is (κ, λ) -finitary when viewed as a functor from $\mathcal{C}_{<\lambda}$ to $\mathcal{D}_{<\lambda}$, and therefore also when viewed as a functor from $\mathcal{C}_{<\lambda}$ to $\mathcal{D}$ (Proposition 9.3.2.16). Applying Corollary 9.3.6.11, we deduce that F is (κ, μ) -finitary. To complete the proof, we must show that for every (κ, μ) -compact object $C \in \mathcal{C}$, the image $F(C) \in \mathcal{D}$ is also (κ, μ) -compact. Assumption (1) guarantees that $F(C)$ belongs to $\mathcal{D}_{<\lambda}$, and assumption (2) guarantees that $F(C)$ is (κ, λ) -compact as an object of $\mathcal{D}_{<\lambda}$. Applying Example 9.3.6.13, we conclude that $F(C)$ is (κ, μ) -compact when viewed as an object of $\mathcal{D} \simeq \text{Ind}_\lambda^\mu(\mathcal{D}_{<\lambda})$. $\square$

Corollary 9.4.2.19. *Let $\kappa \leq \lambda \leq \mu$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -compactly generated, and let $\mathcal{D}$ be an ∞ -category which is (κ, λ) -cocomplete. If $\mathcal{D}$ is idempotent-complete, then the construction $F \mapsto \text{Ind}_\lambda^\mu(F)$ induces an equivalence of ∞ -categories* 06HN

$$\text{Fun}^{(\kappa, \lambda)-c}(\mathcal{C}, \mathcal{D}) \simeq \text{Fun}^{(\kappa, \mu)-c}(\text{Ind}_\lambda^\mu(\mathcal{C}), \text{Ind}_\lambda^\mu(\mathcal{D}))$$

Proof. For $\kappa = \lambda$, this is a special case of Example 9.4.2.11 (which does not require the assumption $\lambda \leq \mu$). We may therefore assume that $\lambda > \kappa$. In this case, $\mathcal{C}$ and $\mathcal{D}$ are idempotent-complete, and can therefore be identified with the full subcategories of $\text{Ind}_\lambda^\mu(\mathcal{C})$ and $\text{Ind}_\lambda^\mu(\mathcal{D})$ spanned by the (λ, μ) -compact objects (Corollary 9.4.1.21). In this case, the desired result is a reformulation of Proposition 9.4.2.18. $\square$

9.4.3 Compact Generation of Oriented Fiber Products

Let $F_- : \mathcal{C}_- \rightarrow \mathcal{C}$ and $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$ be functors of ∞ -categories. Recall that the *oriented fiber product* $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ is an ∞ -category whose objects are triples (C_-, C_+, u) where C_- is an object of $\mathcal{C}_-$, C_+ is an object of $\mathcal{C}_+$, and $u : F_-(C_-) \rightarrow F_+(C_+)$ is a morphism in $\mathcal{C}$ (Construction 4.6.4.1). In this section, we study conditions which guarantee that the ∞ -category $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ is compactly generated. We can state a preliminary version of our main result as follows: 06HP

Proposition 9.4.3.1. *Let $\mathcal{C}_-$, $\mathcal{C}_+$, and $\mathcal{C}$ be compactly generated ∞ -categories, and let $F_- : \mathcal{C}_- \rightarrow \mathcal{C}$ and $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$ be functors. Assume that F_- is compact and that F_+ is finitary. Then:* 06HQ

- *The oriented fiber product $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ is compactly generated.*
- *An object (C_-, C_+, u) of $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ is compact if and only if C_- is a compact object of $\mathcal{C}_-$ and C_+ is a compact object of $\mathcal{C}_+$.*

Proposition 9.4.3.1 is a special case of the following more precise result:

06HR Theorem 9.4.3.2. *Let $F_- : \mathcal{C}_- \rightarrow \mathcal{C}$ and $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$ be functors of ∞ -categories and let $\kappa \leq \lambda$ be regular cardinals satisfying the following conditions:*

- (a) *The ∞ -categories $\mathcal{C}_-$ and $\mathcal{C}_+$ are (κ, λ) -compactly generated.*
- (b) *The ∞ -category $\mathcal{C}$ is (κ, λ) -cocomplete.*
- (c) *The functor F_- is (κ, λ) -compact and the functor F_+ is (κ, λ) -finitary.*

Then:

- *The oriented fiber product $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ is (κ, λ) -compactly generated.*
- *An object (C_-, C_+, u) of $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ is (κ, λ) -compact if and only if C_- is a (κ, λ) -compact object of $\mathcal{C}_-$ and C_+ is a (κ, λ) -compact object of $\mathcal{C}_+$.*

06HS Warning 9.4.3.3. In the situation of Theorem 9.4.3.2, the homotopy fiber product $\mathcal{C}_- \times_{\mathcal{C}}^h \mathcal{C}_+$ need not be (κ, λ) -compactly generated (even if we make the additional assumption that F_+ preserves (κ, λ) -compact objects). We will return to this point in §9.4.4.

We will give the proof of Theorem 9.4.3.2 at the end of this section. First, let us collect some consequences.

06HT Corollary 9.4.3.4. *Let κ be a small regular cardinal, let $\mathcal{C}_-$, $\mathcal{C}_+$, and $\mathcal{C}$ be κ -compactly generated ∞ -categories, let $F_- : \mathcal{C}_- \rightarrow \mathcal{C}$ be a κ -compact functor, and let $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$ be a κ -finitary functor. Then the oriented fiber product $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ is κ -compactly generated. Moreover, an object of $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ is κ -compact if and only if its images in $\mathcal{C}_-$ and $\mathcal{C}_+$ are κ -compact.*

Proof. Apply Theorem 9.4.3.2 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal. □

Proof of Proposition 9.4.3.1. Apply Corollary 9.4.3.4 in the special case $\kappa = \aleph_0$. □

06HU Corollary 9.4.3.5 (Compact Generation of Slice ∞ -Categories). *Let $\kappa \leq \lambda$ be regular cardinals and let $\mathcal{C}$ be a (κ, λ) -compactly generated ∞ -category. Then, for every κ -small diagram $F : K \rightarrow \mathcal{C}$, the slice ∞ -category $\mathcal{C}_{/F}$ is (κ, λ) -compactly generated. Moreover, an object of $\mathcal{C}_{/F}$ is (κ, λ) -compact if and only if its image in $\mathcal{C}$ is (κ, λ) -compact.*

Proof. It follows from Example 9.4.2.9 that the diagonal map $\mathcal{C} \rightarrow \text{Fun}(K, \mathcal{C})$ is a (κ, λ) -compact functor. Applying Theorem 9.4.3.2, we conclude that the oriented fiber product $\mathcal{C} \tilde{\times}_{\text{Fun}(K, \mathcal{C})} \{F\}$ is (κ, λ) -compactly generated, and that an object of $\mathcal{C} \tilde{\times}_{\text{Fun}(K, \mathcal{C})} \{F\}$ is (κ, λ) -compact if and only if its image in $\mathcal{C}$ is (κ, λ) -compact. The desired result now follows from the equivalence $\mathcal{C}_{/F} \hookrightarrow \mathcal{C} \tilde{\times}_{\text{Fun}(K, \mathcal{C})} \{F\}$ supplied by Theorem 4.6.4.19. □

Example 9.4.3.6. Let $\mathcal{C}$ be a compactly generated ∞ -category. Then, for every object $C \in \mathcal{C}$, the slice ∞ -category $\mathcal{C}_{/C}$ is compactly generated. Moreover, an object of $\mathcal{C}_{/C}$ is compact if and only if its image in the ∞ -category $\mathcal{C}$ is compact. 06HV

Corollary 9.4.3.7 (Compact Generation of Coslice ∞ -Categories). *Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be a (κ, λ) -compactly generated ∞ -category, and let $F : K \rightarrow \mathcal{C}$ be a κ -small diagram which carries each vertex of K to a (κ, λ) -compact object of $\mathcal{C}$. Then the coslice ∞ -category $\mathcal{C}_{F/}$ is (κ, λ) -compactly generated. Moreover, an object of $\mathcal{C}_{F/}$ is (κ, λ) -compact if and only if its image in $\mathcal{C}$ is (κ, λ) -compact.* 06HW

Proof. As in the proof of Corollary 9.4.3.5, we note that the diagonal map $\delta : \mathcal{C} \rightarrow \text{Fun}(K, \mathcal{C})$ is (κ, λ) -compact and in particular (κ, λ) -finitary. Our assumption that F carries each vertex of K to a (κ, λ) -compact object of $\mathcal{C}$ guarantees that F is (κ, λ) -compact when viewed as an object of the ∞ -category $\text{Fun}(K, \mathcal{C})$ (Proposition 9.2.8.7). Applying Theorem 9.4.3.2, we conclude that the oriented fiber product $\{F\} \tilde{\times}_{\text{Fun}(K, \mathcal{C})} \mathcal{C}$ is (κ, λ) -compactly generated, and that an object of $\{F\} \tilde{\times}_{\text{Fun}(K, \mathcal{C})} \mathcal{C}$ is (κ, λ) -compact if and only if its image in $\mathcal{C}$ is (κ, λ) -compact. The desired result now follows from the equivalence $\mathcal{C}_{F/} \hookrightarrow \{F\} \tilde{\times}_{\text{Fun}(K, \mathcal{C})} \mathcal{C}$ supplied by Theorem 4.6.4.19. □

Example 9.4.3.8. Let $\mathcal{C}$ be a compactly generated ∞ -category. Then, for every compact object $C \in \mathcal{C}$, the coslice ∞ -category $\mathcal{C}_{C/}$ is compactly generated. Moreover, an object of $\mathcal{C}_{C/}$ is compact if and only if its image in the ∞ -category $\mathcal{C}$ is compact. 06HX

Corollary 9.4.3.9. *Let $\kappa \leq \lambda$ be regular cardinals, let $\mathcal{C}$ be a (κ, λ) -compactly generated ∞ -category, and let $(Q, \leq)$ be a finite partially ordered set. Then the ∞ -category $\text{Fun}(\mathbf{N}_\bullet(Q), \mathcal{C})$ is (κ, λ) -compactly generated. Moreover, an object $F \in \text{Fun}(\mathbf{N}_\bullet(Q), \mathcal{C})$ is (κ, λ) -compact if and only if, for each $q \in Q$, the object $F(q) \in \mathcal{C}$ is (κ, λ) -compact.* 06HY

Proof. We proceed by induction on the number of elements of Q . If Q is empty, the result is clear. Otherwise, we can choose a maximal element $q \in Q$. Set

$$Q_{\leq q} = \{p \in Q : p \leq q\} \quad Q_{< q} = \{p \in Q : p < q\} \quad Q_0 = \{q \in Q : p \neq q\},$$

so that Example 4.6.4.10 supplies an equivalence of ∞ -categories

$$\text{Fun}(\mathbf{N}_\bullet(Q), \mathcal{C}) \rightarrow \text{Fun}(\mathbf{N}_\bullet(Q_0), \mathcal{C}) \tilde{\times}_{\text{Fun}(\mathbf{N}_\bullet(Q_{< q}), \mathcal{C})} \mathcal{C}.$$

The desired result now follows by combining our inductive hypothesis with Theorem 9.4.3.2. □

Example 9.4.3.10. Let $\mathcal{C}$ be a compactly generated ∞ -category. Then, for every finite partially ordered set, the ∞ -category $\text{Fun}(\mathbf{N}_\bullet(Q), \mathcal{C})$ is compactly generated. Moreover, an object $F \in \text{Fun}(\mathbf{N}_\bullet(Q), \mathcal{C})$ is compact if and only if, for each object $q \in Q$, the image $F(q)$ is a compact object of $\mathcal{C}$. 06HZ

06J0 **Warning 9.4.3.11.** The conclusion of Example 9.4.3.8 is not necessarily true if we replace $N_\bullet(Q)$ by a general finite simplicial set (for example, it can fail for the simplicial circle $\Delta^1/\partial\Delta^1$: see Warning 9.2.9.3).

06J1 **Corollary 9.4.3.12.** *Let $\mathcal{C}_-$ and $\mathcal{C}_+$ be compactly generated ∞ -categories. Then the product $\mathcal{C}_- \times \mathcal{C}_+$ is also compactly generated. Moreover, an object $(C_-, C_+) \in \mathcal{C}_- \times \mathcal{C}_+$ is compact if and only if C_- is a compact object of $\mathcal{C}_-$ and C_+ is a compact object of $\mathcal{C}_+$.*

Proof. Apply Proposition 9.4.3.1 in the special case $\mathcal{C} = \Delta^0$. $\square$

For later use, we record an infinitary version of Corollary 9.4.3.12.

06J2 **Proposition 9.4.3.13.** *Let $\kappa \leq \lambda$ be regular cardinals and let $\{C_i\}_{i \in I}$ be a collection of (κ, λ) -compactly generated ∞ -categories indexed by a κ -small set I . Then the product $\mathcal{C} = \prod_{i \in I} C_i$ is also a (κ, λ) -compactly generated ∞ -category. Moreover, an object $\{C_i\}_{i \in I} \in \mathcal{C}$ is (κ, λ) -compact if and only if each C_i is (κ, λ) -compact as an object of C_i .*

Proof. For each $i \in I$, let $\mathcal{C}_i^0$ be the full subcategory of C_i spanned by the (κ, λ) -compact objects. Set $\mathcal{C}^0 = \prod_{i \in I} \mathcal{C}_i^0$, which we regard as a full subcategory of $\mathcal{C}$. Since I is κ -small, Proposition 9.2.8.4 guarantees that every object of $\mathcal{C}^0$ is (κ, λ) -compact when viewed as an object of $\mathcal{C}$. To show that $\mathcal{C}$ is (κ, λ) -compactly generated, it will suffice to show that every object $C \in \mathcal{C}$ can be realized as the colimit of λ -small κ -filtered diagram in $\mathcal{C}^0$.

Write $C = \{C_i\}_{i \in I}$. For each $i \in I$, the assumption $\kappa \leq \lambda$ guarantees that C_i can be realized as the colimit of a diagram $F_i : N_\bullet(A_i) \rightarrow \mathcal{C}_i^0$, where $(A_i, \leq)$ is a λ -small κ -directed partially ordered set (Remark 9.4.1.10). Set $A = \prod_{i \in I} A_i$, so that the collection $\{F_i\}_{i \in I}$ determines a product functor $F : N_\bullet(A) \rightarrow \mathcal{C}^0$. Beware that A need not be λ -small. However, the disjoint union $X = \coprod_{i \in I} A_i$ is λ -small. Applying our assumption $\kappa \leq \lambda$, we deduce that there is a collection of κ -small subsets $\{X_j \subseteq X\}_{j \in J}$ indexed by a λ -small set J , having the property that every κ -small subset of X is contained in some X_j . For every pair of indices $i \in I$, $j \in J$, the intersection $A_i \cap X_j$ is κ -small, and therefore admits an upper bound $b_{i,j} \in A_i$. For each $j \in J$, we can regard the tuple $\{b_{i,j}\}_{i \in I}$ as an element $b_j \in A$. Then $B = \{b_j\}_{j \in J}$ is a λ -small subset of A . By construction, every κ -small subset of A has an upper bound in B , so that B is κ -directed. Moreover, for each $i \in I$, the composite map $B \hookrightarrow A \twoheadrightarrow A_i$ satisfies the criterion of Example 9.1.4.10, and therefore induces a right cofinal functor $N_\bullet(B) \rightarrow N_\bullet(A_i)$. Applying Corollary 7.2.2.11, we deduce that C_i is a colimit of the diagram

$$N_\bullet(B) \hookrightarrow N_\bullet(A) \xrightarrow{F} \mathcal{C}^0 \rightarrow \mathcal{C}_i^0.$$

Invoking Example 7.1.3.11, we see that $C = \{C_i\}_{i \in I}$ is a colimit of the λ -small κ -filtered diagram $N_\bullet(B) \hookrightarrow N_\bullet(A) \xrightarrow{\prod_{i \in I} F_i} \mathcal{C}^0$.

We complete the proof by observing that if the object $C \in \mathcal{C}$ is (κ, λ) -compact, then it is a retract of $F(b)$ for some $b \in B$, and therefore also belongs to $\mathcal{C}^0$. $\square$

Corollary 9.4.3.14. *Let κ be a small regular cardinal and let $\{\mathcal{C}_i\}_{i \in I}$ be a collection of ∞ -categories indexed by a κ -small set I . If each $\mathcal{C}_i$ is κ -compactly generated, then the product $\mathcal{C} = \prod_{i \in I} \mathcal{C}_i$ is also κ -compactly generated. Moreover, an object $\{C_i\}_{i \in I} \in \mathcal{C}$ is κ -compact if and only if each C_i is κ -compact as an object of $\mathcal{C}_i$.* 06J3

Proof. Apply Proposition 9.4.3.13 in the special case where $\lambda = \Omega$ is a strongly inaccessible cardinal. $\square$

We now turn to the proof of Theorem 9.4.3.2. To address set-theoretic technicalities, we will need the following observation:

Lemma 9.4.3.15. *Let λ be an uncountable regular cardinal, let $\mathcal{C}$ be a λ -small simplicial set, and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a left fibration of simplicial sets. Assume that $\mathcal{E}$ is weakly contractible. Then there is a weakly contractible λ -small subset $\mathcal{E}' \subseteq \mathcal{E}$ such that $U|_{\mathcal{E}'}$ is also a left fibration.* 06J4

Proof. If K and L are subsets of $\mathcal{E}$, let us write $K \subseteq L$ if K is contained in L and the following addition conditions are satisfied:

(a) For $0 \leq i < n$, every lifting problem

$$\begin{array}{ccc} \Lambda_i^n & \xrightarrow{\sigma_0} & \mathcal{E} \\ \downarrow & \nearrow \sigma & \downarrow U \\ \Delta^n & \xrightarrow{\quad} & \mathcal{C} \end{array}$$

having the property that σ_0 factors through K admits a solution, where the n -simplex σ is contained in L .

(b) For every finite simplicial subset $K_0 \subseteq K$, the composite map $K_0 \hookrightarrow L \hookrightarrow \text{Ex}^\infty(L)$ is nullhomotopic.

If K is λ -small, then the collection of finite simplicial subsets $K_0 \subseteq K$ and the collection of all lifting problems of the above form are both λ -small. We can then use our assumptions that $\mathcal{E}$ is weakly contractible and that U is a left fibration to choose a λ -small subset $L \subseteq \mathcal{E}$ satisfying $K \subseteq L$. Applying this observation repeatedly, we can choose a sequence of λ -small sets

$$\emptyset = K(0) \subseteq K(1) \subseteq K(2) \subseteq K(3) \subseteq \cdots$$

The union $\mathcal{E}' = \bigcup_{n \geq 0} K(n)$ then has the desired properties. $\square$

Proof of Theorem 9.4.3.2. Let $\kappa \leq \lambda$ be regular cardinals and let $F_- : \mathcal{C}_- \rightarrow \mathcal{C}$ and $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$ be functors of ∞ -categories which satisfy conditions (a), (b), and (c) of Theorem

9.4.3.2. Let $\mathcal{C}_\pm$ be the oriented fiber product $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ and let $\mathcal{C}_\pm^0$ denote the full subcategory of $\mathcal{C}_\pm$ spanned by those objects (C_-, C_+, u) where C_- is a (κ, λ) -compact object of $\mathcal{C}_-$ and C_+ is a (κ, λ) -compact object of $\mathcal{C}_+$. Proposition 7.1.9.4 guarantees that the ∞ -category $\mathcal{C}_\pm$ is (κ, λ) -cocomplete. Let $\mathcal{C}_\pm^1 \subseteq \mathcal{C}_\pm$ be the smallest full subcategory which contains $\mathcal{C}_\pm^0$ and is closed under λ -small κ -filtered colimits. Note that every object of $\mathcal{C}_\pm^0$ is (κ, λ) -compact when viewed as an object of $\mathcal{C}_\pm$ (Proposition 9.2.8.1), and therefore also as an object of $\mathcal{C}_\pm^1$. Applying Proposition 9.3.2.3, we conclude that the inclusion functor $\mathcal{C}_\pm^0 \hookrightarrow \mathcal{C}_\pm^1$ exhibits $\mathcal{C}_\pm^1$ as an $\text{Ind}_\kappa^\lambda$ -completion of $\mathcal{C}_\pm^0$. It follows that the ∞ -category $\mathcal{C}_\pm^1$ is (κ, λ) -compactly generated, and that an object of $\mathcal{C}_\pm^1$ is (κ, λ) -compact if and only if it is a retract of an object of $\mathcal{C}_\pm^0$ (Lemma 9.4.1.18). Since $\mathcal{C}_\pm^0$ is closed under retracts (Remark 9.2.5.18), every such retract is already contained in $\mathcal{C}_\pm^0$. We will complete the proof by showing that $\mathcal{C}_\pm^1 = \mathcal{C}_\pm$.

Let us say that an object $C_- \in \mathcal{C}_-$ is *good* if, for every object $C_+ \in \mathcal{C}_+$ and every morphism $u : F_-(C_-) \rightarrow F_+(C_+)$, the triple (C_-, C_+, u) belongs to the full subcategory $\mathcal{C}_\pm^1 \subseteq \mathcal{C}$. We wish to show that every object of $\mathcal{C}_-$ is good. Since $\mathcal{C}_-$ is (κ, λ) -compactly generated, it will suffice to prove the following:

- (a) The collection of good objects of $\mathcal{C}_-$ is closed under λ -small κ -filtered colimits.
- (b) Every (κ, λ) -compact object of $\mathcal{C}_-$ is good.

We first prove (a). Suppose we are given a λ -small κ -filtered ∞ -category $\mathcal{J}$ and a colimit diagram $G_- : \mathcal{J}^\triangleright \rightarrow \mathcal{C}_-$ which carries each object of $\mathcal{J}$ to a good object of $\mathcal{C}_-$; we wish to show that the object $C_- = G_-(P)$ is also good, where P denotes the cone point of $\mathcal{J}^\triangleright$. Fix a morphism $u : F_-(C_-) \rightarrow F_+(C_+)$ as above. Since the projection map $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \{C_+\} \rightarrow \mathcal{C}_-$ is a right fibration and the inclusion map $\{P\} \hookrightarrow \mathcal{J}^\triangleright$ is right anodyne (Example 4.3.7.11), we can lift G_- to a diagram $G_\pm : \mathcal{J}^\triangleright \rightarrow \mathcal{C}_\pm$ such that $G_\pm(P) = (C_-, C_+, u)$ and the composition $\mathcal{J}^\triangleright \xrightarrow{G_\pm} \mathcal{C}_\pm \rightarrow \mathcal{C}_+$ is the constant functor taking the value C_+ . Applying Lemma 7.1.9.3, we see that $G_\pm$ is a colimit diagram in the ∞ -category $\mathcal{C}_\pm$. By construction, the restriction $G_\pm|_{\mathcal{J}}$ factors through $\mathcal{C}_\pm^1$, so that $G_\pm(P) = (C_-, C_+, u)$ also belongs to $\mathcal{C}_\pm^1$.

We now prove (b). For the remainder of the proof, we fix an object $C_- \in \mathcal{C}_-$ which is (κ, λ) -compact; we wish to show that C_- is good. Let us say that an object $C_+ \in \mathcal{C}_+$ is *good* if, for every morphism $u : F_-(C_-) \rightarrow F_+(C_+)$ in the ∞ -category $\mathcal{C}$, the triple $C_\pm = (C_-, C_+, u)$ is contained in $\mathcal{C}_\pm^1$. Note that, if C_+ is (κ, λ) -compact, then this condition is automatic (since $C_\pm$ is an object of the subcategory $\mathcal{C}_\pm^0 \subseteq \mathcal{C}_\pm^1$). Using our assumption that $\mathcal{C}_+$ is (κ, λ) -compactly generated, we are reduced to proving the following:

- (c) The collection of good objects of $\mathcal{C}_+$ is closed under λ -small κ -filtered colimits.

Fix a λ -small κ -filtered ∞ -category $\mathcal{K}$ and a colimit diagram $H : \mathcal{K}^\triangleright \rightarrow \mathcal{C}_+$ carrying each object of $\mathcal{K}$ to a good object of $\mathcal{C}_+$; we wish to show that $C_+ = H(Q)$ is also good, where

$Q \in \mathcal{K}^\triangleright$ denotes the cone point. Set $\mathcal{E} = \{C_-\} \tilde{\times}_{\mathcal{C}} \mathcal{K}$ and $\bar{\mathcal{E}} = \{C_-\} \tilde{\times}_{\mathcal{C}} \mathcal{K}^\triangleright$, so that projection onto the second factors determines left fibrations

$$U : \mathcal{E} \rightarrow \mathcal{K} \quad \bar{U} : \bar{\mathcal{E}} \rightarrow \mathcal{K}^\triangleright.$$

Fix an uncountable cardinal μ of cofinality $\geq \lambda$ such that $\mathcal{C}$ is locally μ -small, so that the left fibration $\bar{U}$ admits a covariant transport representation given by the composition

$$\mathcal{K}^\triangleright \xrightarrow{H} \mathcal{C}_+ \xrightarrow{F_+} \mathcal{C} \xrightarrow{\text{Hom}_{\mathcal{C}}(F_-(C_-), \bullet)} \mathcal{S}_{<\mu}$$

Since the functor F_+ is (κ, λ) -finitely and the object $F_-(C_-)$ is (κ, λ) -compact, this composite functor is a colimit diagram in $\mathcal{S}_{<\mu}$. Applying Corollary 7.4.3.14, we see that the inclusion map $\mathcal{E} \hookrightarrow \bar{\mathcal{E}}$ is a weak homotopy equivalence.

Fix a morphism $u : F_-(C_-) \rightarrow F_+(C_+)$ in the ∞ -category $\mathcal{C}$; we wish to show that the triple $C_\pm = (C_-, C_+, u)$ belongs to the full subcategory $\mathcal{C}_\pm^1 \subseteq \mathcal{C}_\pm$. Let us regard the triple (C_-, Q, u) as an object $\tilde{Q} \in \bar{\mathcal{E}}$ satisfying $\bar{U}(\tilde{Q}) = Q$. Since $\bar{U}$ is a left fibration, the induced map

$$\bar{V} : \bar{\mathcal{E}}_{/\tilde{Q}} \rightarrow \bar{\mathcal{E}} \times_{\mathcal{K}^\triangleright} (\mathcal{K}^\triangleright)_{/Q} \simeq \bar{\mathcal{E}}$$

is a Kan fibration (Proposition 4.3.7.2). Set $\mathcal{E}_{/\tilde{Q}} = \mathcal{E} \times_{\bar{\mathcal{E}}} \bar{\mathcal{E}}_{/\tilde{Q}}$ so that projection onto the second factor induces Kan fibration $V : \mathcal{E}_{/\tilde{Q}} \rightarrow \mathcal{E}$. Note that the ∞ -category $\bar{\mathcal{E}}_{/\tilde{Q}}$ has a final object (Proposition 4.6.7.23) and is therefore weakly contractible (Corollary 4.6.7.26). It follows from Corollary 3.3.7.4 that the inclusion map $\mathcal{E}_{/\tilde{Q}} \hookrightarrow \bar{\mathcal{E}}_{/\tilde{Q}}$ is also a weak homotopy equivalence, so that the ∞ -category $\mathcal{E}_{/\tilde{Q}}$ is weakly contractible. Applying Lemma 9.4.3.15 to the left fibration $(U \circ V) : \mathcal{E}_{/\tilde{Q}} \rightarrow \mathcal{K}$, we can choose a weakly contractible λ -small subset $\mathcal{K}' \subseteq \mathcal{E}_{/\tilde{Q}}$ for which the restriction $(U \circ V)|_{\mathcal{K}'} : \mathcal{K}' \rightarrow \mathcal{K}$ is a left fibration. Applying Corollary 9.1.5.14 (and Remark 9.1.3.7), we conclude that $\mathcal{K}'$ is a κ -filtered ∞ -category and that the functor $T = (U \circ V)|_{\mathcal{K}'}$ is right cofinal. The composition

$$\mathcal{K}^\triangleright \hookrightarrow \bar{\mathcal{E}}_{/\tilde{Q}} \rightarrow \bar{\mathcal{E}} = \{C_-\} \tilde{\times}_{\mathcal{C}} \mathcal{K}^\triangleright \rightarrow C_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$$

determines a diagram $H' : \mathcal{K}^\triangleright \rightarrow \mathcal{C}_\pm$, whose image in $\mathcal{C}_-$ is the constant diagram taking the value C_- and whose image in $\mathcal{C}_+$ is given by the composition $H \circ T^\triangleright$. Applying Corollary 7.2.2.3 and Lemma 7.1.9.3, we deduce that H' is a colimit diagram in the ∞ -category $\mathcal{C}_\pm$. Our assumption on H guarantees that $H'|_{\mathcal{K}'}$ factors through the full subcategory $\mathcal{C}_\pm^1$. Since $\mathcal{C}_\pm^1$ is closed under λ -small κ -filtered colimits, we conclude that the object $C_\pm = (C_-, C_+, u)$ also belong to $\mathcal{C}_\pm^1$. $\square$

9.4.4 Compact Generation of Homotopy Fiber Products

Let κ be a small regular cardinal. Suppose we are given κ -compactly generated ∞ -categories $\mathcal{C}_-$, $\mathcal{C}_+$ and $\mathcal{C}$, together with κ -compact functors $F_- : \mathcal{C}_- \rightarrow \mathcal{C}$ and $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$. Then Corollary 9.4.3.4 asserts that the oriented fiber product $\mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ is also κ -compactly generated. Beware that the analogous statement need not hold for the homotopy fiber product $\mathcal{C}_- \times_{\mathcal{C}}^h \mathcal{C}_+$.

06J6 Exercise 9.4.4.1. Let $\mathcal{C}$ be (the nerve of) the category whose objects are linearly ordered sets and whose morphisms are strictly increasing functions. Let $\mathcal{C}_- \subseteq \mathcal{C}$ be the full subcategory spanned by those linearly ordered sets $(Q, \leq)$ where Q is either infinite or of even cardinality, and let $\mathcal{C}_+ \subseteq \mathcal{C}$ be the full subcategory spanned by those linearly ordered sets $(Q, \leq)$ where Q is either infinite or of odd cardinality. Show that:

- The ∞ -categories $\mathcal{C}_-$, $\mathcal{C}_+$, and $\mathcal{C}$ are compactly generated.
- The inclusion functors $\mathcal{C}_- \hookrightarrow \mathcal{C} \hookleftarrow \mathcal{C}_+$ are compact.
- The homotopy fiber product $\mathcal{C}_- \times_{\mathcal{C}}^h \mathcal{C}_+$ is nonempty but does not contain any compact objects. In particular, it is not compactly generated.

Our goal in this section is to show that, under some additional assumptions, we can avoid the phenomenon illustrated in Exercise 9.4.4.1. We can state a preliminary version of our main result as follows:

06J7 Proposition 9.4.4.2. *Let κ be a small uncountable regular cardinal and suppose we are given a categorical pullback diagram of ∞ -categories*

$$\begin{array}{ccc} \mathcal{C}_{\pm} & \xrightarrow{G_+} & \mathcal{C}_+ \\ \downarrow G_- & & \downarrow F_+ \\ \mathcal{C}_- & \xrightarrow{F_-} & \mathcal{C} \end{array}$$

which satisfies the following conditions:

- *The ∞ -categories $\mathcal{C}_-$, $\mathcal{C}_+$, and $\mathcal{C}$ admit small filtered colimits, and the functors F_- and F_+ are finitary.*
- *The ∞ -categories $\mathcal{C}_-$ and $\mathcal{C}_+$ are κ -compactly generated, and the functors F_- and F_+ are κ -compact.*

Then the ∞ -category $\mathcal{C}_{\pm}$ is κ -compactly generated. Moreover, an object $X \in \mathcal{C}_{\pm}$ is κ -compact if and only if $G_-(X)$ and $G_+(X)$ are κ -compact objects of the ∞ -categories $\mathcal{C}_-$ and $\mathcal{C}_+$, respectively.

Warning 9.4.4.3. In the statement of Proposition 9.4.4.2, the assumption that κ is 06J8 uncountable cannot be omitted. In particular, Proposition 9.4.4.2 cannot be used to show that the ∞ -category $\mathcal{C}_\pm$ is compactly generated (or to characterize the compact objects of $\mathcal{C}_\pm$). See Exercise 9.4.4.1.

Proposition 9.4.4.2 is a consequence of the following more general result:

Theorem 9.4.4.4. Let $\kappa \trianglelefteq \lambda$ be regular cardinals, let $\mathcal{C}_-$ and $\mathcal{C}_+$ be ∞ -categories which are 06J9 (κ, λ) -compactly generated, and let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -cocomplete. Suppose we are given a categorical pullback diagram of ∞ -categories

$$\begin{array}{ccc} \mathcal{C}_\pm & \xrightarrow{G_+} & \mathcal{C}_+ \\ \downarrow G_- & & \downarrow F_+ \\ \mathcal{C}_- & \xrightarrow{F_-} & \mathcal{C}, \end{array}$$

where the functors F_- and F_+ are (κ, λ) -compact. Assume that the following additional condition is satisfied:

- ($\star$) Let $\mathcal{C}_-^0$ and $\mathcal{C}_+^0$ be the full subcategories of $\mathcal{C}_-$ and $\mathcal{C}_+$ spanned by the (κ, λ) -compact objects. Then there exists a regular cardinal $\kappa_0 < \kappa$ such that $\mathcal{C}_-^0$ and $\mathcal{C}_+^0$ admit κ_0 -sequential colimits, which are preserved by the functors F_- and F_+ .

Then the ∞ -category $\mathcal{C}_\pm$ is (κ, λ) -compactly generated. Moreover, an object $X \in \mathcal{C}_\pm$ is (κ, λ) -compact if and only if $G_-(X)$ and $G_+(X)$ are (κ, λ) -compact objects of the ∞ -categories $\mathcal{C}_-$ and $\mathcal{C}_+$, respectively.

Remark 9.4.4.5. In the situation of Theorem 9.4.4.4, suppose that we are given a functor 06JA of ∞ -categories $H : \mathcal{D} \rightarrow \mathcal{C}_\pm$. Then:

- If $\mathcal{D}$ is (κ, λ) -cocomplete, then H is (κ, λ) -finitary if and only if the functors $(G_- \circ H) : \mathcal{D} \rightarrow \mathcal{C}_-$ and $(G_+ \circ H) : \mathcal{D} \rightarrow \mathcal{C}_+$ are (κ, λ) -finitary.
- If $\mathcal{D}$ is (κ, λ) -compactly generated, then H is (κ, λ) -compact if and only if the functors $G_- \circ H$ and $G_+ \circ H$ are (κ, λ) -compact.

The first assertion is a special case of Proposition 7.1.9.1, and the second follows by combining Proposition 7.1.9.1 with the characterization of (κ, λ) -compact objects of $\mathcal{C}_\pm$ supplied by Theorem 9.4.4.4.

Applying this observation in the special case where H is the identity functor $\text{id}_{\mathcal{C}_\pm}$, we see that the functors $G_- : \mathcal{C}_\pm \rightarrow \mathcal{C}_-$ and $G_+ : \mathcal{C}_\pm \rightarrow \mathcal{C}_+$ are (κ, λ) -compact.

06JB **Remark 9.4.4.6.** In the situation of Theorem 9.4.4.4, a diagram $N_\bullet(\text{Ord}_{<\kappa_0}) \rightarrow \mathcal{C}_-^0$ admits a colimit in $\mathcal{C}_-^0$ if and only if it admits a colimit in the ∞ -category $\mathcal{C}_-$, which case the colimits are the same (see Remark 9.4.1.16). Condition $(\star)$ is therefore a consequence of the following stronger condition:

$(\star^+)$ There exists a regular cardinal $\kappa_0 < \kappa$ for which the ∞ -categories $\mathcal{C}_-$ and $\mathcal{C}_+$ admit κ_0 -sequential colimits, and the functors F_- and F_+ preserve κ_0 -sequential colimits.

Proof of Proposition 9.4.4.2. Apply Theorem 9.4.4.4 in the special case where $\kappa_0 = \aleph_0$ and $\lambda = \Omega$ is a strongly inaccessible cardinal. $\square$

06JC **Corollary 9.4.4.7** (Compact Generation of Inverse Limits). *Let $\kappa \leq \lambda$ be regular cardinals and suppose we are given a tower of ∞ -categories*

$$\cdots \rightarrow \mathcal{C}_3 \xrightarrow{U_2} \mathcal{C}_2 \xrightarrow{U_1} \mathcal{C}_1 \xrightarrow{U_0} \mathcal{C}_0.$$

Assume that each of the ∞ -categories $\mathcal{C}_n$ is (κ, λ) -compactly generated, and that each of the functors U_n is a (κ, λ) -compact isofibration, and that the following additional condition is satisfied:

$(\star)$ *There exists a regular cardinal $\kappa_0 < \kappa$ such that, for each $n \geq 0$, the full subcategory $\mathcal{C}_n^0 \subseteq \mathcal{C}_n$ spanned by the (κ, λ) -compact objects admits κ_0 -sequential colimits, which are preserved by functors $U_n|_{\mathcal{C}_{n+1}^0} : \mathcal{C}_{n+1}^0 \rightarrow \mathcal{C}_n^0$.*

Then the inverse limit $\varprojlim(\mathcal{C}_n)$ is (κ, λ) -compactly generated. Moreover, an object $X = \{X_n\}_{n \geq 0} \in \varprojlim(\mathcal{C}_n)$ is (κ, λ) -compact if and only if each X_n is a (κ, λ) -compact object of $\mathcal{C}_n$.

Proof. Set $\mathcal{C} = \prod_n \mathcal{C}_n$. Since κ is uncountable, Proposition 9.4.3.13 implies that $\mathcal{C}$ is (κ, λ) -compactly generated, and that an object $\{X_n\}_{n \geq 0} \in \mathcal{C}$ is (κ, λ) -compact if and only if each X_n is a (κ, λ) -compact object of $\mathcal{C}_n$. Moreover, an analogous statement holds for the product $\mathcal{C} \times \mathcal{C}$. Let $S : \mathcal{C} \rightarrow \mathcal{C}$ be the shift functor (given on objects by the construction $\{X_n\}_{n \geq 0} \mapsto \{U_n(X_{n+1})\}_{n \geq 0}$). The desired result now follows by applying Theorem 9.4.4.4 to the categorical pullback square

$$\begin{array}{ccc} \varprojlim(\mathcal{C}_n) & \xrightarrow{\quad} & \mathcal{C} \\ \downarrow & & \downarrow (\text{id}, \text{id}) \\ \mathcal{C} & \xrightarrow{(\text{id}, S)} & \mathcal{C} \times \mathcal{C} \end{array}$$

supplied by Corollary 4.5.6.19. $\square$

Corollary 9.4.4.8. *Let κ be a small uncountable regular cardinal and suppose we are given* 06JD
a tower of ∞ -categories

$$\cdots \rightarrow \mathcal{C}_3 \xrightarrow{U_2} \mathcal{C}_2 \xrightarrow{U_1} \mathcal{C}_1 \xrightarrow{U_0} \mathcal{C}_0.$$

Assume that each of the ∞ -categories $\mathcal{C}_n$ is κ -compactly generated and admits small filtered colimits and that each of the functors $U_n : \mathcal{C}_{n+1} \rightarrow \mathcal{C}_n$ is a finitary isofibration which preserves κ -compact objects. Then the limit $\varprojlim (\mathcal{C}_n)$ is κ -compactly generated. Moreover, an object $X = \{X_n\}_{n \geq 0} \in \varprojlim (\mathcal{C}_n)$ is κ -compact if and only if each X_n is a κ -compact object of $\mathcal{C}_n$.

Proof. Apply Corollary 9.4.4.7 in the special case where $\kappa_0 = \aleph_0$ and $\lambda = \Omega$ is a strongly inaccessible cardinal. $\square$

We begin by proving a slight variant of Theorem 9.4.4.4, where we replace the hypothesis $\kappa \leq \lambda$ by set-theoretic assumptions on the ∞ -categories themselves.

Theorem 9.4.4.9. *Let $\kappa \leq \lambda$ be regular cardinals and suppose we are given a categorical* 06JE
pullback diagram of ∞ -categories

$$\begin{array}{ccc} \mathcal{C}_{\pm} & \xrightarrow{G_+} & \mathcal{C}_+ \\ \downarrow G_- & & \downarrow F_+ \\ \mathcal{C}_- & \xrightarrow{F_-} & \mathcal{C} \end{array} \quad (9.12) \quad 06JF$$

Assume that:

- (a) *The ∞ -categories $\mathcal{C}_-$, $\mathcal{C}_+$, and $\mathcal{C}$ are (κ, λ) -compactly generated, and the functors F_- and F_+ are (κ, λ) -compact.*
- (b) *The full subcategories $\mathcal{C}_-^0 \subseteq \mathcal{C}_-$, $\mathcal{C}_+^0 \subseteq \mathcal{C}_+$, and $\mathcal{C}^0 \subseteq \mathcal{C}$ spanned by the (κ, λ) -compact objects are essentially λ -small.*
- (c) *There exists a regular cardinal $\kappa_0 < \kappa$ for which the ∞ -categories $\mathcal{C}_-^0$ and $\mathcal{C}_+^0$ admit κ_0 -sequential colimits, which are preserved by the functors F_- and F_+ .*

Then the ∞ -category $\mathcal{C}_{\pm}$ is (κ, λ) -compactly generated. Moreover, an object $X \in \mathcal{C}_{\pm}$ is (κ, λ) -compact if and only if $G_-(X)$ and $G_+(X)$ are (κ, λ) -compact objects of the ∞ -categories $\mathcal{C}_-$ and $\mathcal{C}_+$, respectively.

Proof. Let $\mathcal{C}_{\pm}^0$ denote the full subcategory of $\mathcal{C}_{\pm}$ spanned by those objects X such that $G_-(X)$ and $G_+(X)$ are (κ, λ) -compact, so that (9.12) restricts to a categorical pullback

sqaure

$$\begin{array}{ccc} \mathcal{C}_{\pm}^0 & \xrightarrow{G_+^0} & \mathcal{C}_+^0 \\ \downarrow G_-^0 & & \downarrow F_+^0 \\ \mathcal{C}_-^0 & \xrightarrow{F_-^0} & \mathcal{C}^0. \end{array}$$

It follows from Proposition 7.1.9.1 that the ∞ -category $\mathcal{C}_{\pm}$ is (κ, λ) -cocomplete. Moreover Corollary 9.2.8.3 guarantees that every object of $\mathcal{C}_{\pm}^0$ is (κ, λ) -compact when regarded as an object of $\mathcal{C}_{\pm}$. To show that $\mathcal{C}_{\pm}$ is (κ, λ) -accessible, it will suffice to show that every object $X_{\pm} \in \mathcal{C}_{\pm}$ can be realized as the colimit of an essentially λ -small κ -filtered diagram in $\mathcal{C}_{\pm}^0$. Lemma 9.4.1.18 then guarantees that every (κ, λ) -compact object of $\mathcal{C}_{\pm}$ is a retract of an object of $\mathcal{C}_{\pm}^0$. Since $\mathcal{C}_{\pm}^0$ is closed under retracts (Remark 9.2.5.18), we conclude that an object of $\mathcal{C}_{\pm}$ is (κ, λ) -compact if and only if it belongs to $\mathcal{C}_{\pm}^0$.

Fix an object $X_{\pm} \in \mathcal{C}_{\pm}$ as above. Set $X_- = G_-(X_{\pm})$, $X_+ = G_+(X_{\pm})$, and $X = F_+(X_+) = F_-(X_-)$. Let $\mathcal{K}$ denote the fiber product $\mathcal{C}^0 \times_{\mathcal{C}} \mathcal{C}/X$, and define ∞ -categories $\mathcal{K}_-$, $\mathcal{K}_+$, and $\mathcal{K}_{\pm}$ similarly, so that Corollary 4.6.4.22 supplies a categorical pullback square

$$\begin{array}{ccc} \mathcal{K}_{\pm} & \xrightarrow{g_+} & \mathcal{K}_+ \\ \downarrow g_- & & \downarrow f_+ \\ \mathcal{K}_- & \xrightarrow{f_-} & \mathcal{K}. \end{array}$$

Applying Corollary 9.3.4.15, we see that the ∞ -categories $\mathcal{K}_-$, $\mathcal{K}_+$, and $\mathcal{K}$ are κ -filtered and essentially λ -small. Using Corollary 4.7.5.17, we see that $\mathcal{K}_{\pm}$ is also essentially λ -small. Note that $\text{Ind}_{\kappa}^{\lambda}(f_-)$ can be identified with the functor $(\mathcal{C}_-)/_{X_-} \rightarrow \mathcal{C}/X$ induced by F_- . In particular, $\text{Ind}_{\kappa}^{\lambda}(f_-)$ preserves final objects, so f_- is right cofinal (Proposition 9.3.7.11). Similarly, the functor $f_+ : \mathcal{K}_+ \rightarrow \mathcal{K}$ is right cofinal. Combining assumption (c) with Proposition 9.2.5.23 and Corollary 7.1.4.22, we deduce that the ∞ -categories $\mathcal{K}_-$, $\mathcal{K}_+$ and $\mathcal{K}$ are κ_0 -sequentially cocomplete, and that the functors f_- and f_+ preserve κ_0 -sequential colimits. Invoking Theorem 9.2.4.3, we conclude that the ∞ -category $\mathcal{K}_{\pm}$ is κ -filtered and that the functors g_- and g_+ are right cofinal. We will complete the proof by showing that the composite map

$$\bar{q} : \mathcal{K}_{\pm}^{\triangleright} \rightarrow (\mathcal{C}_{\pm})_{/X_{\pm}}^{\triangleright} \rightarrow \mathcal{C}_{\pm}$$

is a colimit diagram in the ∞ -category $\mathcal{C}_{\pm}$. Note that $G_- \circ \bar{q}$ can be written as a composition

$$\mathcal{K}_{\pm}^{\triangleright} \xrightarrow{g_-^{\triangleright}} \mathcal{K}_-^{\triangleright} \rightarrow (\mathcal{C}_-)/_{X_-}^{\triangleright} \rightarrow \mathcal{C}_-,$$

which is a colimit diagram by virtue Corollary 9.3.4.15 together with the right cofinality of g_- (Corollary 7.2.2.3). A similar argument shows that $G_+ \circ \bar{q}$ is a colimit diagram in the ∞ -category $\mathcal{C}_+$, so that $\bar{q}$ is a colimit diagram by Proposition 7.1.9.8. $\square$

The following is a restatement of Theorem 9.4.4.9:

Corollary 9.4.4.10. *We Let $\kappa \leq \lambda$ be regular cardinals and let $F_- : \mathcal{C}_- \rightarrow \mathcal{C}$ and $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$ be functors of ∞ -categories satisfying conditions (a), (b), and (c) of Theorem 9.4.4.9. Then the homotopy fiber product $\mathcal{C}_- \times_{\mathcal{C}}^h \mathcal{C}_+$ is (κ, λ) -compactly generated. Moreover, an object of $\mathcal{C}_- \times_{\mathcal{C}}^h \mathcal{C}_+$ is (κ, λ) -compact if and only if its images in $\mathcal{C}_-$ and $\mathcal{C}_+$ are (κ, λ) -compact.* 06JG

Proof. Using Corollary 4.5.2.24 (and Corollary 4.5.2.21), we can reduce to the case where $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$ is an isofibration. In this case, the inclusion map $\mathcal{C}_- \times_{\mathcal{C}} \mathcal{C}_+ \hookrightarrow \mathcal{C}_- \times_{\mathcal{C}}^h \mathcal{C}_+$ is an equivalence of ∞ -categories (Corollary 4.5.2.29). The desired result now follows by applying Theorem 9.4.4.9 to the diagram

$$\begin{array}{ccc} \mathcal{C}_- \times_{\mathcal{C}} \mathcal{C}_+ & \xrightarrow{\quad} & \mathcal{C}_+ \\ \downarrow & & \downarrow F_+ \\ \mathcal{C}_- & \xrightarrow{F_-} & \mathcal{C} \end{array}$$

which is a categorical pullback square by virtue of Corollary 4.5.2.28. $\square$

We now return to Theorem 9.4.4.4. Recall that a diagram of ∞ -categories

$$\begin{array}{ccc} \mathcal{C}_{\pm} & \xrightarrow{G_+} & \mathcal{C}_+ \\ \downarrow G_- & & \downarrow F_+ \\ \mathcal{C}_- & \xrightarrow{F_-} & \mathcal{C} \end{array}$$

is a categorical pullback square if and only if the functors G_- and G_+ induce an equivalence from $\mathcal{C}_{\pm}$ to the homotopy fiber product $\mathcal{C}_- \times_{\mathcal{C}}^h \mathcal{C}_+$. It will therefore suffice to prove the following:

Proposition 9.4.4.11. *Let $\kappa \trianglelefteq \lambda$ be regular cardinals and let $F_- : \mathcal{C}_- \rightarrow \mathcal{C}$ and $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$ be functors of ∞ -categories satisfying the following conditions:* 06JH

- *The ∞ -categories $\mathcal{C}_-$ and $\mathcal{C}_+$ are (κ, λ) -compactly generated and the ∞ -category $\mathcal{C}$ is (κ, λ) -cocomplete.*

- The functor F_- and F_+ are (κ, λ) -compact.
- There exists a regular cardinal $\kappa_0 < \kappa$ for which the full subcategories of (κ, λ) -compact objects $\mathcal{C}_-^0 \subseteq \mathcal{C}_-$ and $\mathcal{C}_+^0 \subseteq \mathcal{C}_+$ admits κ_0 -sequential colimits, which are preserved by the functors F_- and F_+ .

Then the homotopy fiber product $\mathcal{C}_\pm = \mathcal{C}_- \times_{\mathcal{C}}^h \mathcal{C}_+$ is (κ, λ) -compactly generated. Moreover, an object of $\mathcal{C}_\pm$ is (κ, λ) -compact if and only if its images in $\mathcal{C}_-$ and $\mathcal{C}_+$ are (κ, λ) -compact.

Proof. Let $\mathcal{C}^0 \subseteq \mathcal{C}$ be the full subcategory spanned by the (κ, λ) -compact objects and let $\mathcal{C}' \subseteq \mathcal{C}$ be the smallest full subcategory which contains $\mathcal{C}^0$ and is closed under λ -small κ -filtered colimits. Then $\mathcal{C}'$ is (κ, λ) -compactly generated and our hypotheses guarantee that the functors F_- and F_+ factor through $\mathcal{C}'$. We may therefore replace $\mathcal{C}$ by $\mathcal{C}'$ and thereby reduce to the case where $\mathcal{C}$ is also (κ, λ) -compactly generated.

Fix a regular cardinal μ satisfying $\lambda \trianglelefteq \mu$ such that $\mathcal{C}_-$, $\mathcal{C}_+$, and $\mathcal{C}$ are essentially μ -small. Without loss of generality, we may assume that $\mathcal{C}_-$, $\mathcal{C}_+$ and $\mathcal{C}$ are given as full subcategories of their Ind_λ^μ -completions $\widehat{\mathcal{C}}_- = \text{Ind}_\lambda^\mu(\mathcal{C}_-)$, $\widehat{\mathcal{C}}_+ = \text{Ind}_\lambda^\mu(\mathcal{C}_+)$, and $\widehat{\mathcal{C}} = \text{Ind}_\lambda^\mu(\mathcal{C})$, and that F_- and F_+ are the restrictions of (λ, μ) -compact functors $\widehat{F}_- : \widehat{\mathcal{C}}_- \rightarrow \widehat{\mathcal{C}}$ and $\widehat{F}_+ : \widehat{\mathcal{C}}_+ \rightarrow \widehat{\mathcal{C}}$. Applying Propositions 9.4.1.25, we see that the ∞ -categories $\widehat{\mathcal{C}}_-$, $\widehat{\mathcal{C}}_+$, and $\widehat{\mathcal{C}}$ are (κ, μ) -compactly generated, and that their full subcategories of (κ, μ) -compact objects can be identified with $\mathcal{C}_-^0$, $\mathcal{C}_+^0$ and $\mathcal{C}^0$, respectively. Applying Corollary 9.4.4.10 for the pairs $(\lambda \leq \mu)$ and $(\kappa \leq \mu)$, we obtain the following:

- The ∞ -category $\widehat{\mathcal{C}}_\pm = \widehat{\mathcal{C}}_- \times_{\widehat{\mathcal{C}}}^h \widehat{\mathcal{C}}_+$ is (λ, μ) -compactly generated. Moreover, an object of $\widehat{\mathcal{C}}_\pm$ is (λ, μ) -compact if and only if it belongs to the full subcategory $\mathcal{C}_\pm$.
- The ∞ -category $\widehat{\mathcal{C}}_\pm$ is (κ, μ) -compactly generated. Moreover, an object of $\widehat{\mathcal{C}}_\pm$ is (κ, μ) -compact if and only if it belongs to the full subcategory $\mathcal{C}_\pm^0 = \mathcal{C}_-^0 \times_{\mathcal{C}^0}^h \mathcal{C}_+^0$.

Applying Corollary 9.4.1.26, we see that the ∞ -category $\mathcal{C}_\pm$ is (κ, λ) -compactly generated, and that an object of $\mathcal{C}_\pm$ is (κ, λ) -compact if and only if it belongs to the full subcategory $\mathcal{C}_\pm^0$. $\square$

9.4.5 Compactly Generated Fibrations

06JJ It will sometimes be useful to consider a relative version of Definition 9.4.1.1:

06JK **Definition 9.4.5.1.** Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. We say that U is *compactly generated* if, for every n -simplex $\sigma : \Delta^n \rightarrow \mathcal{C}$, the fiber product $\mathcal{E}_\sigma = \Delta^n \times_{\mathcal{C}} \mathcal{E}$ is a compactly generated ∞ -category (in the sense of Definition 9.4.1.1).

06JL **Variant 9.4.5.2.** Let κ be a small regular cardinal and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. We say that U is *κ -compactly generated* if, for every n -simplex $\Delta^n \rightarrow \mathcal{C}$,

the fiber product $\mathcal{E}_\sigma = \Delta^n \times_{\mathcal{C}} \mathcal{E}$ is a κ -compactly generated ∞ -category (in the sense of Definition 9.4.1.5).

Remark 9.4.5.3. An inner fibration of simplicial sets $U : \mathcal{E} \rightarrow \mathcal{C}$ is compactly generated (in the sense of Definition 9.4.5.1) if and only if it is $\aleph_0$ -compactly generated (in the sense of Variant 9.4.5.2). 06JM

Variant 9.4.5.4. Let $\kappa \leq \lambda$ be regular cardinals and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. We say that U is (κ, λ) -compactly generated if, for every n -simplex $\Delta^n \rightarrow \mathcal{C}$, the fiber product $\mathcal{E}_\sigma = \Delta^n \times_{\mathcal{C}} \mathcal{E}$ is a (κ, λ) -compactly generated ∞ -category (in the sense of Variant 9.4.1.7). 06JN

Remark 9.4.5.5. Let κ be a small regular cardinal. Following the convention of Remark 4.7.0.5, an inner fibration $U : \mathcal{E} \rightarrow \mathcal{C}$ is κ -compactly generated (in the sense of Variant 9.4.5.2) if and only if it is (κ, Ω) -compactly generated (in the sense of Variant 9.4.5.4), where Ω denotes some fixed strongly inaccessible cardinal. 06JP

Example 9.4.5.6. Let $\kappa \leq \lambda$ be regular cardinals. Then an ∞ -category $\mathcal{E}$ is (κ, λ) -compactly generated (in the sense of Variant 9.4.1.7) if and only if the projection map $\mathcal{E} \rightarrow \Delta^0$ is a (κ, λ) -compactly generated inner fibration (in the sense of Variant 9.4.5.4). 06JQ

Remark 9.4.5.7. Let $\kappa \leq \lambda$ be regular cardinals, and suppose we are given a pullback diagram of simplicial sets 06JR

$$\begin{array}{ccc} \mathcal{E}' & \xrightarrow{\quad} & \mathcal{E} \\ \downarrow U' & & \downarrow U \\ \mathcal{C}' & \xrightarrow{F} & \mathcal{C} \end{array}$$

If U is a (κ, λ) -compactly generated inner fibration, then U' has the same property.

It follows from Example 9.4.5.6 and Remark 9.4.5.7 that if $U : \mathcal{E} \rightarrow \mathcal{C}$ is a (κ, λ) -compactly generated inner fibration, then each fiber of U is a (κ, λ) -compactly generated ∞ -category. The converse is not quite true.

Corollary 9.4.5.8. Let $\kappa \leq \lambda$ be regular cardinals and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a locally cartesian fibration of simplicial sets. Then U is (κ, λ) -compactly generated if and only if the following pair of conditions is satisfied: 06JS

- (a) For every vertex C of $\mathcal{C}$, the ∞ -category $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is (κ, λ) -compactly generated.
- (b') For every edge $e : C \rightarrow C'$ of $\mathcal{C}$, the contravariant transport functor $e^* : \mathcal{E}_{C'} \rightarrow \mathcal{E}_C$ is (κ, λ) -finitary.

Proof. Let $e : C \rightarrow C'$ be an edge of $\mathcal{C}$, let $\mathcal{E}_e$ be the fiber product $\Delta^1 \times_{\mathcal{C}} \mathcal{E}$, and regard $\mathcal{E}_C$ and $\mathcal{E}_{C'}$ as full subcategories of $\mathcal{E}_e$. Since the projection map $\mathcal{E}_e \rightarrow \Delta^1$ is a cartesian fibration, the full subcategory $\mathcal{E}_C \subseteq \mathcal{E}_e$ is coreflective (Corollary 6.2.5.2) and therefore closed under the formation of colimits (Variant 7.1.4.26). By virtue of Proposition 9.4.5.11, it will suffice to show that the following conditions are equivalent:

(b_e) Every (κ, λ) -compact object of $\mathcal{E}_C$ is also (κ, λ) -compact as an object of $\mathcal{E}_e$.

(b'_e) The contravariant transport functor $e^* : \mathcal{E}_{C'} \rightarrow \mathcal{E}_C$ is (κ, λ) -finitary.

Fix a regular cardinal $\mu \geq \lambda$ such that $\mathcal{E}_e$ is locally μ -small and let X be a (κ, λ) -compact object of $\mathcal{E}_C$, and let $h^X : \mathcal{E}_e \rightarrow \mathcal{S}_{<\mu}$ be the functor corepresented by X . Using Remark 9.2.9.13, we see that X is (κ, λ) -compact as an object of $\mathcal{E}_e$ if and only if the restriction $h^X|_{\mathcal{E}_{C'}} : \mathcal{E}_{C'} \rightarrow \mathcal{S}_{<\mu}$ is (κ, λ) -finitary. Identifying $h^X|_{\mathcal{E}_{C'}}$ with the composite functor $\mathcal{E}_{C'} \xrightarrow{e^*} \mathcal{E}_C \xrightarrow{h^X|_{\mathcal{E}_C}} \mathcal{S}_{<\mu}$, the equivalence (b_e) $\Leftrightarrow$ (b'_e) now follows from Corollary 9.4.1.17. $\square$

06JT Corollary 9.4.5.9. *Let $\kappa \leq \lambda$ be regular cardinals and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a locally cocartesian fibration of simplicial sets. Then U is (κ, λ) -compactly generated if and only if the following pair of conditions is satisfied:*

(a) *For every vertex C of $\mathcal{C}$, the ∞ -category $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is (κ, λ) -compactly generated.*

(b') *For every edge $e : C \rightarrow C'$ of $\mathcal{C}$, the covariant transport functor $e_! : \mathcal{E}_{C'} \rightarrow \mathcal{E}_C$ is (κ, λ) -compact.*

Proof. Let $e : C \rightarrow C'$ be an edge of $\mathcal{C}$, let $\mathcal{E}_e$ be the fiber product $\Delta^1 \times_{\mathcal{C}} \mathcal{E}$, and regard $\mathcal{E}_C$ and $\mathcal{E}_{C'}$ as full subcategories of $\mathcal{E}_e$. Without loss of generality, we may assume that the cocartesian fibration U is (κ, λ) -cocomplete, so that the covariant transport functor $e_! : \mathcal{E}_C \rightarrow \mathcal{E}_{C'}$ is (κ, λ) -finitary (see Remark 9.2.9.8). By virtue of Proposition 9.4.5.11, it will suffice to show that the following conditions are equivalent:

(b_e) Every (κ, λ) -compact object $X \in \mathcal{E}_C$ is also (κ, λ) -compact as an object of $\mathcal{E}_e$.

(b'_e) For every (κ, λ) -compact object $X \in \mathcal{E}_C$, the image $e_!(X)$ is (κ, λ) -compact as an object of $\mathcal{E}_{C'}$.

Fix a regular cardinal $\mu \geq \lambda$ such that $\mathcal{E}_e$ is locally μ -small and let $h^X : \mathcal{E}_e \rightarrow \mathcal{S}_{<\mu}$ be the functor corepresented by X . Since the restriction $h^X|_{\mathcal{E}_{C'}} : \mathcal{E}_{C'} \rightarrow \mathcal{S}_{<\mu}$ is corepresented by the object $e_!(X)$, the equivalence (b_e) $\Leftrightarrow$ (b'_e) is a special case of Remark 9.2.9.13. $\square$

06JU Proposition 9.4.5.10. *Let $\kappa \leq \lambda$ be regular cardinals and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. The following conditions are equivalent:*

- (1) The inner fibration U is (κ, λ) -compactly generated (in the sense of Definition 9.4.5.1).
 (2) There exists a commutative diagram of simplicial sets

$$\begin{array}{ccc}
 \mathcal{E}_0 & \xrightarrow{H} & \mathcal{E} \\
 & \searrow U_0 & \swarrow U \\
 & \mathcal{C}, &
 \end{array}$$

where U_0 is an inner fibration and H exhibits U as an $\mathrm{Ind}_\kappa^\lambda$ -completion of U_0 (see Definition 9.3.3.13).

Moreover, if these conditions are satisfied, then we can take $\mathcal{E}_0$ to be the full simplicial subset of $\mathcal{E}$ spanned by those vertex X which are (κ, λ) -compact when viewed as objects of the ∞ -category $\{U(X)\} \times_{\mathcal{C}} \mathcal{E}$.

Proof. The implication (2) $\Rightarrow$ (1) follows immediately from Proposition 9.4.1.11. To prove the converse, let $\mathcal{E}_0 \subseteq \mathcal{E}$ be the full simplicial subset of $\mathcal{E}$ spanned by those vertices X which are (κ, λ) -compact when viewed as objects of $\{U(X)\} \times_{\mathcal{C}} \mathcal{E}$. We wish to show that, if U is (κ, λ) -compactly generated, then the inclusion map $\mathcal{E}_0 \hookrightarrow \mathcal{E}$ exhibits U as an $\mathrm{Ind}_\kappa^\lambda$ -completion of the inner fibration $U_0 = U|_{\mathcal{E}_0}$. Fix an n -simplex $\sigma : \Delta^n \rightarrow \mathcal{C}$; we wish to show that $\Delta^n \times_{\mathcal{C}} \mathcal{E}$ is an $\mathrm{Ind}_\kappa^\lambda$ -completion of $\Delta^n \times_{\mathcal{C}} \mathcal{E}_0$. Replacing $\mathcal{C}$ by Δ^n , we can reduce to the case where $\mathcal{C} = \Delta^n$ is a standard simplex. In this case, we wish to show that $\mathcal{E}$ is an $\mathrm{Ind}_\kappa^\lambda$ -completion of the full subcategory $\mathcal{E}_0$. Since $\mathcal{E}$ is (κ, λ) -compactly generated, it will suffice to show that $\mathcal{E}_0$ is the full subcategory of $\mathcal{E}$ spanned by the (κ, λ) -compact objects (Proposition 9.4.1.11), which was established in the proof of Proposition 9.4.5.11. $\square$

Proposition 9.4.5.11. *Let $\kappa \leq \lambda$ be regular cardinals and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner 06JV fibration of simplicial sets. Then U is (κ, λ) -compactly generated (in the sense of Variant 9.4.5.4) if and only if the following conditions are satisfied:*

- (a) For every vertex $C \in \mathcal{C}$, the ∞ -category $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is (κ, λ) -compactly generated.
 (b) If $e : C \rightarrow C'$ is an edge of $\mathcal{C}$, then the inclusion functor $\mathcal{E}_C \hookrightarrow \Delta^1 \times_{\mathcal{C}} \mathcal{E}$ is (κ, λ) -finitary. Moreover, every (κ, λ) -compact object of the ∞ -category $\mathcal{E}_C$ is also (κ, λ) -compact when viewed as an object of the ∞ -category $\Delta^1 \times_{\mathcal{C}} \mathcal{E}$.

Proof. Assume first that the inner fibration U is (κ, λ) -compactly generated. Condition (1) then follows from Example 9.4.5.6 and Remark 9.4.5.7. To verify condition (2), we may assume without loss of generality that $\mathcal{C} = \Delta^1$ and that e is the nondegenerate edge of $\mathcal{C}$, so that $\mathcal{E} \simeq \Delta^1 \times_{\mathcal{C}} \mathcal{E}$ is (κ, λ) -compactly generated. It follows from Remark 9.2.9.13 that

the inclusion map $\mathcal{E}_C \hookrightarrow \mathcal{E}$ is (κ, λ) -finitary: that is, $\mathcal{E}_C$ is closed under the formation of λ -small κ -filtered colimits in $\mathcal{E}$. To verify condition (2), it will suffice to show that every (κ, λ) -compact object $X \in \mathcal{E}_C$ is (κ, λ) -compact when viewed as an object of $\mathcal{E}$. Since $\mathcal{E}$ is (κ, λ) -compactly generated, we can realize X as the colimit of a λ -small κ -filtered diagram $F : \mathcal{K} \rightarrow \mathcal{E}$. Since X belongs to $\mathcal{E}_C$, the diagram F automatically factors through $\mathcal{E}_C$. Our assumption that X is (κ, λ) -compact as an object of $\mathcal{E}_C$ then guarantees that it is a retract of $F(K)$ for some object $K \in \mathcal{K}$. Since $F(K)$ is (κ, λ) -compact as an object of $\mathcal{E}$ then guarantees that X is also (κ, λ) -compact as an object of $\mathcal{E}$ (Remark 9.2.5.18).

We now prove the converse. Assume that U satisfies conditions (1) and (2); we wish to show that U is (κ, λ) -compactly generated. Fix a simplex $\sigma : \Delta^n \rightarrow \mathcal{C}$; we wish to show that the fiber product $\mathcal{E}_\sigma = \Delta^n \times_{\mathcal{C}} \mathcal{E}$ is (κ, λ) -compactly generated. Replacing $\mathcal{E}$ by $\mathcal{E}_\sigma$, we may assume that $\mathcal{C} = \Delta^n$ is a standard simplex, and we wish to show that $\mathcal{E}$ is (κ, λ) -compactly generated. Invoking Proposition 9.2.9.7, we deduce that the ∞ -category $\mathcal{E}$ is (κ, λ) -cocomplete, and that the inclusion functor $\mathcal{E}_C \hookrightarrow \mathcal{E}$ is (κ, λ) -finitary for each $C \in \mathcal{C}$. Fix an object $X \in \mathcal{E}$ having image $C = U(X)$ in $\mathcal{C}$. Our assumption that $\mathcal{E}_C$ is (κ, λ) -compactly generated guarantees that we can realize X as the colimit of a λ -small κ -filtered diagram $F : \mathcal{K} \rightarrow \mathcal{E}_C$ having the property that for each $K \in \mathcal{K}$, $F(K)$ is (κ, λ) -compact as an object of $\mathcal{E}_C$. To complete the proof, it will suffice to show that $F(K)$ is also (κ, λ) -compact when viewed as an object of $\mathcal{E}$. Fix a regular cardinal $\mu \geq \lambda$ such that $\mathcal{E}$ is locally μ -small, and let $h^X : \mathcal{E} \rightarrow \mathcal{S}_{<\mu}$ be the functor corepresented by X ; we wish to show that h^X is (κ, λ) -finitary. By virtue of Remark 9.2.9.13, it will suffice to show that the restriction $h^X|_{\mathcal{E}_{C'}}$ for every object $C' \in \mathcal{C}$. If $C \leq C'$ (as elements of the partially ordered set $[n] = \{0, 1, \dots, n\}$), this follows from assumption (2). Otherwise, $h^X|_{\mathcal{E}_{C'}}$ is the constant functor taking the value $\emptyset$, and the result follows from Example 9.2.2.12. $\square$

06JW Proposition 9.4.5.12. *Let $\kappa \leq \lambda$ be regular cardinals, let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets which is (κ, λ) -compactly generated.*

- (1) *The ∞ -category of sections $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ is (κ, λ) -cocomplete.*
- (2) *Let $F : \mathcal{C} \rightarrow \mathcal{E}$ be a section of U such that, for each vertex $C \in \mathcal{C}$, the object $F(C) \in \mathcal{E}_C$ is (κ, λ) -compact. If $\mathcal{C}$ is κ -small, then F is (κ, λ) -compact as an object of $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$.*
- (3) *Let $\mathcal{E}_0 \subseteq \mathcal{E}$ be the full simplicial subset spanned by those vertices X which are (κ, λ) -compact as objects of the ∞ -category $\mathcal{E}_C$ for $C = U(X)$. Then the inclusion $\mathcal{E}_0 \hookrightarrow \mathcal{E}$ induces a fully faithful functor*

$$\mathrm{Ind}_{\kappa}^{\lambda}(\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E}_0)) \rightarrow \mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E}).$$

Proof. Assertion (1) is a special case of Proposition 7.6.6.40, assertion (2) follows from Proposition 9.2.9.16, and assertion (3) is a reformulation of (2) (Proposition 9.3.2.1). $\square$

We now study some further assumptions which guarantee that the comparison map

$$\mathrm{Ind}_\kappa^\lambda(\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E}_0)) \rightarrow \mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$$

of Proposition 9.4.5.12 is an equivalence of ∞ -categories.

Theorem 9.4.5.13. *Let $\kappa \leq \lambda$ be regular cardinals, let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets which is (κ, λ) -compactly generated, and let $\mathcal{E}_0 \subseteq \mathcal{E}$ be the full simplicial subset spanned by those vertices X which are (κ, λ) -compact when viewed as objects of the fiber $\mathcal{E}_C$ for $C = U(X)$. Assume that $\mathcal{C}$ is κ -small and that the inner fibration $(U_0 = U|_{\mathcal{E}_0}) : \mathcal{E}_0 \rightarrow \mathcal{C}$ is κ_0 -sequentially cocomplete, for some regular cardinal $\kappa_0 < \kappa$ (see Variant 9.2.9.5). Then:*

- (1) *The ∞ -category of sections $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ is (κ, λ) -compactly generated.*
- (2) *An object $F \in \mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ is (κ, λ) -compact if and only if it factors through $\mathcal{E}_0 \subseteq \mathcal{E}$.*

In particular, the natural map $\mathrm{Ind}_\kappa^\lambda(\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E}_0)) \rightarrow \mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ is an equivalence of ∞ -categories.

Proof. We proceed as in the proof of Proposition 9.2.8.7. We say that a simplicial set $\mathcal{C}'$ equipped with a map $\mathcal{C}' \rightarrow \mathcal{C}$ is *good* if the ∞ -category $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}', \mathcal{E})$ is (κ, λ) -compactly generated, and an object $F \in \mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}', \mathcal{E})$ is (κ, λ) -compact if and only if $F(C) \in \mathcal{E}_C$ is (κ, λ) -compact for each vertex $C \in \mathcal{C}'$. We will complete the proof by showing that if $\mathcal{C}'$ is κ -small, then it is good.

Note that $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}', \mathcal{E})$ can be realized as the inverse limit of a tower of ∞ -categories

$$\cdots \rightarrow \mathrm{Fun}_{/\mathcal{C}}(\mathrm{sk}_2(\mathcal{C}'), \mathcal{E}) \rightarrow \mathrm{Fun}_{/\mathcal{C}}(\mathrm{sk}_1(\mathcal{C}'), \mathcal{E}) \rightarrow \mathrm{Fun}_{/\mathcal{C}}(\mathrm{sk}_0(\mathcal{C}'), \mathcal{E})$$

where the transition maps are isofibrations (Corollary 4.4.5.12). It follows from Corollary 9.4.4.7 that if each $\mathrm{sk}_n(\mathcal{C}')$ is good, then $\mathcal{C}'$ is good. We may therefore replace $\mathcal{C}'$ by $\mathrm{sk}_n(\mathcal{C}')$, and thereby reduce to the case where the simplicial set $\mathcal{C}'$ has dimension $\leq n$, for some integer $n \geq -1$.

We now proceed by induction on n . If $n = -1$, then the simplicial set $\mathcal{C}'$ is empty and the result is clear. Otherwise, let $\mathcal{C}'' = \mathrm{sk}_{n-1}(\mathcal{C}')$ be the $(n-1)$ -skeleton of $\mathcal{C}'$ and let S be the collection of all nondegenerate n -simplices of $\mathcal{C}$. Applying Proposition 1.1.4.12, we obtain a pullback diagram of ∞ -categories

$$\begin{array}{ccc} \mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}', \mathcal{E}) & \longrightarrow & \mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}'', \mathcal{E}) \\ \downarrow & & \downarrow \\ \mathrm{Fun}_{/\mathcal{C}}(\coprod_{\sigma \in S} \Delta^n, \mathcal{E}) & \longrightarrow & \mathrm{Fun}_{/\mathcal{C}}(\coprod_{\sigma \in S} \partial \Delta^n, \mathcal{E}). \end{array}$$

Since the horizontal maps in this diagram are isofibrations (Corollary 4.4.5.12), it is also a categorical pullback square (Corollary 4.5.2.28). Our inductive hypothesis guarantees that $\mathcal{C}''$ and $\coprod_{\sigma \in S} \partial \Delta^n$ are good. By virtue of Theorem 9.4.4.4, to prove that $\mathcal{C}'$ is good, it will suffice to show that the disjoint union $\coprod_{\sigma \in S} \Delta^n$ is good. Using Proposition 9.4.3.13, can further reduce to the case where $\mathcal{C}' = \Delta^n$ is the standard n -simplex.

Let $\text{Spine}[n] \subseteq \Delta^n$ be as in Example 1.5.7.7. The inclusion $\text{Spine}[n] \hookrightarrow \Delta^n$ is inner anodyne and therefore induces a trivial Kan fibration $\text{Fun}_{/\mathcal{C}}(\Delta^n, \mathcal{E}) \rightarrow \text{Fun}_{/\mathcal{C}}(\text{Spine}[n], \mathcal{E})$. Consequently, to show that Δ^n is good, it will suffice to show that $\text{Spine}[n]$ is good. For $n \geq 2$, this follows from our inductive hypothesis. If $n = 0$, then the map $\mathcal{C}' \rightarrow \mathcal{C}$ can be identified with a vertex $C \in \mathcal{C}$, and the desired result follows from our assumption that the ∞ -category $\mathcal{E}_C$ is (κ, λ) -compactly generated. We may therefore assume that $n = 1$. Replacing U by the projection map $\mathcal{C}' \times_{\mathcal{C}} \mathcal{E} \rightarrow \mathcal{C}'$, we are reduced to proving Theorem 9.4.5.13 in the special case where $\mathcal{C} = \Delta^1$ is the standard 1-simplex. Set $\mathcal{E}_0 = \{0\} \times_{\mathcal{C}} \mathcal{E}$ and $\mathcal{E}_1 = \{1\} \times_{\mathcal{C}} \mathcal{E}$. Then $\text{Fun}_{/\Delta^1}(\Delta^1, \mathcal{C})$ can be identified with the oriented fiber product $\mathcal{E}_0 \tilde{\times}_{\mathcal{E}} \mathcal{E}_1$, and the desired result follows from Theorem 9.4.3.2. $\square$

06JY Corollary 9.4.5.14. *Let $\kappa \trianglelefteq \lambda$ be regular cardinals, let $\mathcal{C}$ be an ∞ -category which is (κ, λ) -compactly generated, and let $\mathcal{C}_{<\kappa} \subseteq \mathcal{C}$ be the full subcategory spanned by the (κ, λ) -compact objects. Assume that there exists a regular cardinal $\kappa_0 < \kappa$ such that $\mathcal{C}_{<\kappa}$ is κ_0 -sequentially cocomplete. Then, for every κ -small simplicial set K , the ∞ -category $\text{Fun}(K, \mathcal{C})$ is (κ, λ) -compactly generated. Moreover, an object $F \in \text{Fun}(K, \mathcal{C})$ is (κ, λ) -compact if and only if, for each vertex $k \in K$, the object $F(k) \in \mathcal{C}$ is (κ, λ) -compact.*

Proof. Apply Theorem 9.4.5.13 to the projection map $\mathcal{C} \times K \rightarrow K$. $\square$

06JZ Remark 9.4.5.15. Let $\kappa \leq \lambda$ be regular cardinals. For any ∞ -category $\mathcal{C}$, postcomposition with the tautological map $\mathcal{C} \rightarrow \text{Ind}_{\kappa}^{\lambda}(\mathcal{C})$ induces a map of diagram ∞ -categories $\text{Fun}(K, \mathcal{C}) \rightarrow \text{Fun}(K, \text{Ind}_{\kappa}^{\lambda}(\mathcal{C}))$, which admits a (κ, λ) -finitary extension

$$\theta : \text{Ind}_{\kappa}^{\lambda}(\text{Fun}(K, \mathcal{C})) \rightarrow \text{Fun}(K, \text{Ind}_{\kappa}^{\lambda}(\mathcal{C})).$$

Proposition 9.4.5.12 implies that if K is κ -small, then θ is fully faithful. Corollary 9.4.5.14 asserts that θ is an equivalence if K is κ -small and $\mathcal{C}$ is κ_0 -sequentially cocomplete for some $\kappa_0 < \kappa$.

06K0 Corollary 9.4.5.16. *Let $\kappa \trianglelefteq \lambda$ be regular cardinals, let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a cocartesian fibration of simplicial sets which is (κ, λ) -compactly generated, and let $\mathcal{E}_0 \subseteq \mathcal{E}$ be the full simplicial subset spanned by those vertices X which are (κ, λ) -compact when viewed as objects of the fiber $\mathcal{E}_C$ for $C = U(X)$. Assume that $\mathcal{C}$ is κ -small and that the inner fibration $(U_0 = U|_{\mathcal{E}_0}) : \mathcal{E}_0 \rightarrow \mathcal{C}$ is κ_0 -sequentially cocomplete, for some regular cardinal $\kappa_0 < \kappa$ (see Variant 9.2.9.5). Then:*

- (1) The ∞ -category of cocartesian sections $\mathrm{Fun}_{/\mathcal{C}}^{\mathrm{CCart}}(\mathcal{C}, \mathcal{E})$ is (κ, λ) -compactly generated.
- (2) An object $F \in \mathrm{Fun}_{/\mathcal{C}}^{\mathrm{CCart}}(\mathcal{C}, \mathcal{E})$ is (κ, λ) -compact if and only if it factors through $\mathcal{E}_0 \subseteq \mathcal{E}$.

In particular, the natural map $\mathrm{Ind}_{\kappa}^{\lambda}(\mathrm{Fun}_{/\mathcal{C}}^{\mathrm{CCart}}(\mathcal{C}, \mathcal{E}_0)) \rightarrow \mathrm{Fun}_{/\mathcal{C}}^{\mathrm{CCart}}(\mathcal{C}, \mathcal{E})$ is an equivalence of ∞ -categories.

Proof. Choose a morphism of λ -small simplicial sets $T : \mathcal{C}' \rightarrow \mathcal{C}$ and set $\mathcal{E}' = \mathcal{C}' \times_{\mathcal{C}} \mathcal{E}$. If T is surjective on edges, then we have a categorical pullback diagram of ∞ -categories

$$\begin{array}{ccc} \mathrm{Fun}_{/\mathcal{C}}^{\mathrm{CCart}}(\mathcal{C}, \mathcal{E}) & \longrightarrow & \mathrm{Fun}_{/\mathcal{C}'}^{\mathrm{CCart}}(\mathcal{C}', \mathcal{E}') \\ \downarrow & & \downarrow \\ \mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E}) & \longrightarrow & \mathrm{Fun}_{/\mathcal{C}'}(\mathcal{C}', \mathcal{E}'). \end{array}$$

Applying Theorems 9.4.4.4 and 9.4.5.13, we are reduced to proving Corollary 9.4.5.16 after replacing U by the projection map $U' : \mathcal{E}' \rightarrow \mathcal{C}'$. We can therefore reduce to the case where the simplicial set $\mathcal{C}$ is a κ -small disjoint union of edges. Using Proposition 9.4.3.13, we can further reduce to the case where $\mathcal{C} = \Delta^1$ is the standard 1-simplex. In this case, the evaluation functor $\mathrm{ev}_0 : \mathrm{Fun}_{/\mathcal{C}}^{\mathrm{CCart}}(\mathcal{C}, \mathcal{E}) \rightarrow \{0\} \times_{\mathcal{C}} \mathcal{E}$ is an equivalence of ∞ -categories (Proposition 5.3.1.21), which immediately implies (1). To prove (2), we must show that if $F : \mathcal{C} \rightarrow \mathcal{E}$ is a cocartesian section of U for which $F(0) \in \{0\} \times_{\mathcal{C}} \mathcal{E}$ is (κ, λ) -compact, then $F(1) \in \{1\} \times_{\mathcal{C}} \mathcal{E}$ is also (κ, λ) -compact. This follows from the observation that the covariant transport functor $\{0\} \times_{\mathcal{C}} \mathcal{E} \rightarrow \{1\} \times_{\mathcal{C}} \mathcal{E}$ is (κ, λ) -compact (see Corollary 9.4.5.9). $\square$

Corollary 9.4.5.17. *Let $\kappa \trianglelefteq \lambda$ be regular cardinals, let $\mathcal{C}$ be a κ -small simplicial set, and suppose we are given a diagram*

$$\mathcal{F} : \mathcal{C} \rightarrow \mathcal{QC} \quad (C \in \mathcal{C}) \mapsto \mathcal{F}(C)$$

having a limit $\varinjlim(\mathcal{F})$. Assume that the following conditions are satisfied:

- For each vertex C of $\mathcal{C}$, the ∞ -category $\mathcal{F}(C)$ is (κ, λ) -compactly generated. We write $\mathcal{F}(C)_{<\kappa}$ for the full subcategory of $\mathcal{F}(C)$ spanned by the (κ, λ) -compact objects.
- For each edge $e : C \rightarrow C'$ of $\mathcal{C}$, the functor $\mathcal{F}(e) : \mathcal{F}(C) \rightarrow \mathcal{F}(C')$ is (κ, λ) -compact.
- There exists a regular cardinal $\kappa_0 < \kappa$ such that each of the ∞ -categories $\mathcal{F}(C)_{<\kappa}$ admits κ_0 -sequential colimits, and each of the functors $\mathcal{F}(e)|_{\mathcal{F}(C)_{<\kappa}} : \mathcal{F}(C)_{<\kappa} \rightarrow \mathcal{F}(C')_{<\kappa}$ preserves κ_0 -sequential colimits.

Then the ∞ -category $\varprojlim(\mathcal{F})$ is (κ, λ) -compactly generated. Moreover, an object of $\varprojlim(\mathcal{F})$ is (κ, λ) -compact if and only if its image in each of the ∞ -categories $\mathcal{F}(C)$ is (κ, λ) -compact.

Proof. Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a cocartesian fibration with covariant transport representation $\mathcal{F}$, so that we can identify the limit $\varprojlim(\mathcal{F})$ with the ∞ -category $\mathrm{Fun}_{/\mathcal{C}}^{\mathrm{CCart}}(\mathcal{C}, \mathcal{E})$ of cocartesian sections of U (Proposition 7.4.4.1). The desired result is now a reformulation of Corollary 9.4.5.16. $\square$

06K2 **Remark 9.4.5.18.** In the formulation of Corollary 9.4.5.17, we have implicitly assumed that the ∞ -categories $\{\mathcal{F}(C)\}_{C \in \mathcal{C}}$ and $\varprojlim(\mathcal{F})$ are small. However, this is not important: the same statement holds if we replace $\mathcal{QC}$ by $\mathcal{QC}_{<\mu}$, for any uncountable cardinal μ (which need not be small).

06K3 **Remark 9.4.5.19.** In the situation of Corollary 9.4.5.17, suppose we are given a functor of ∞ -categories $T : \mathcal{D} \rightarrow \varprojlim(\mathcal{F})$. Then:

- If $\mathcal{D}$ is (κ, λ) -cocomplete, then T is (κ, λ) -finitary if and only if the composite functor $\mathcal{D} \xrightarrow{T} \varprojlim(\mathcal{F}) \rightarrow \mathcal{F}(C)$ is (κ, λ) -finitary for every vertex $C \in \mathcal{C}$.
- If $\mathcal{D}$ is (κ, λ) -compactly generated, then T is (κ, λ) -compact if and only if the composite functor $\mathcal{D} \xrightarrow{T} \varprojlim(\mathcal{F}) \rightarrow \mathcal{F}(C)$ is (κ, λ) -compact for every vertex $C \in \mathcal{C}$.

This follows from Proposition 7.6.6.40 together with the characterization of (κ, λ) -compact objects of $\varprojlim(\mathcal{F})$ supplied by Corollary 9.4.5.17.

06K4 **Corollary 9.4.5.20.** Let $\kappa \trianglelefteq \lambda$ be regular cardinals and let $\mu > \lambda$ be a cardinal of exponential cofinality $\geq \lambda$, so that the functor

$$\mathrm{Ind}_{\kappa}^{\lambda} : \mathcal{QC}_{<\mu} \rightarrow \mathcal{QC}_{<\mu}$$

is well-defined (see Proposition 9.3.3.7). Fix a regular cardinal $\kappa_0 < \kappa$, and let $\mathcal{QC}_{<\mu}^{\kappa_0\text{-seq}} \subseteq \mathcal{QC}_{<\mu}$ denote the subcategory of $\mathcal{QC}_{<\mu}$ whose objects are μ -small ∞ -categories which admit κ_0 -sequential colimits, and whose morphisms are functors which preserve κ_0 -sequential colimits (Notation 9.2.3.4). Then the composite functor

$$\mathcal{QC}_{<\mu}^{\kappa_0\text{-seq}} \hookrightarrow \mathcal{QC}_{<\mu} \xrightarrow{\mathrm{Ind}_{\kappa}^{\lambda}} \mathcal{QC}_{<\mu}$$

preserves κ -small limits.

Proof. We define a subcategory $\mathcal{Q} \subseteq \mathcal{QC}_{<\mu}$ as follows:

- A μ -small ∞ -category $\mathcal{C}$ belongs to $\mathcal{Q}$ if it is (κ, λ) -compactly generated and $\mathcal{C}_{<\kappa}$ is κ_0 -sequentially cocomplete, where $\mathcal{C}_{<\kappa}$ denotes the full subcategory of $\mathcal{C}$ spanned by the (κ, λ) -compact objects.

- If $\mathcal{C}$ and $\mathcal{C}'$ are objects of $\mathcal{Q}$, then a functor $F : \mathcal{C} \rightarrow \mathcal{C}'$ is a morphism of $\mathcal{Q}$ if it is (κ, λ) -compact and the induced map $\mathcal{C}_{<\kappa} \rightarrow \mathcal{C}'_{<\kappa'}$ preserves κ_0 -sequential colimits.

It follows from Remark 9.4.2.16 that the construction $\mathcal{C} \mapsto \text{Ind}_\kappa^\lambda(\mathcal{C})$ induces an equivalence from $\mathcal{QC}_{<\mu}^{\kappa_0\text{-seq}}$ to $\mathcal{Q}$. It will therefore suffice to show that the inclusion functor $\mathcal{Q} \hookrightarrow \mathcal{QC}_{<\mu}$ preserves κ -small limits, which is a reformulation of Corollary 9.4.5.17 (see Remark 9.4.5.19). $\square$

9.4.6 Accessible ∞ -Categories

Let κ be a small regular cardinal. Recall that an ∞ -category $\mathcal{C}$ is κ -*compactly generated* 06K5 if it has the form $\text{Ind}_\kappa(\mathcal{C}_0)$, for some other ∞ -category $\mathcal{C}_0$ (Corollary 9.4.1.13). We now study a slightly stronger condition, where we also control the size of the ∞ -category $\mathcal{C}_0$.

Definition 9.4.6.1. Let κ be a small regular cardinal. We say that an ∞ -category $\mathcal{C}$ is 06K6 κ -*accessible* if there exists a small ∞ -category $\mathcal{C}_0$ such that $\mathcal{C}$ is an Ind_κ -completion of $\mathcal{C}_0$.

Proposition 9.4.6.2. Let $\mathcal{C}$ be an ∞ -category and let κ be a small regular cardinal. The 06K7 following conditions are equivalent:

- (1) The ∞ -category $\mathcal{C}$ is κ -accessible: that is, it is an Ind_κ -completion of a small ∞ -category $\mathcal{C}_0$.
- (2) The ∞ -category $\mathcal{C}$ is an Ind_κ -completion of an essentially λ -small ∞ -category $\mathcal{C}_0$.
- (3) The ∞ -category $\mathcal{C}$ is κ -compactly generated and the full subcategory $\mathcal{C}_{<\kappa} \subseteq \mathcal{C}$ spanned by the κ -compact objects is essentially small.

Proof. The equivalence (1) $\Leftrightarrow$ (2) is immediate from the definitions and the equivalence (2) $\Leftrightarrow$ (3) follows from the description of $\text{Ind}_\kappa^\lambda$ -completions supplied by Theorem 9.3.4.14. The implication (3) $\Rightarrow$ (2) follows Proposition 9.4.1.11. Conversely, if $\mathcal{C}$ is the Ind_κ -completion of an essentially small ∞ -category $\mathcal{C}_0$, then $\mathcal{C}_{<\kappa}$ is an idempotent-completion of $\mathcal{C}_0$ (Proposition 9.4.1.19) and is therefore essentially small (Proposition 8.5.5.7). $\square$

Corollary 9.4.6.3. Let κ be a small regular cardinal. Then the construction $\mathcal{C} \mapsto \text{Ind}_\kappa(\mathcal{C})$ 06K8 induces a bijection

$$\begin{array}{c}
 \{\text{Small idempotent-complete } \infty\text{-categories}\} / \text{Equivalence} \\
 \downarrow \sim \\
 \{\kappa\text{-accessible } \infty\text{-categories}\} / \text{Equivalence}.
 \end{array}$$

06K9 **Remark 9.4.6.4.** Let κ be a small regular cardinal and let $\{\mathcal{C}_i\}_{i \in I}$ be a collection of κ -accessible ∞ -categories. If the index set I is κ -small, then the product $\mathcal{C} = \prod_{i \in I} \mathcal{C}_i$ is also κ -accessible. This follows by combining Proposition 9.4.3.13 with Variant 4.7.5.9.

06KA **Proposition 9.4.6.5.** *Let $\kappa \trianglelefteq \lambda$ be small regular cardinals. Then every κ -accessible ∞ -category $\mathcal{C}$ is also λ -accessible.*

Proof. By assumption, $\mathcal{C}$ can be identified with the Ind_κ -completion of an essentially small ∞ -category $\mathcal{C}_0$. Applying Theorem 9.3.6.4, we conclude that $\mathcal{C}$ is also an Ind_λ -completion of the ∞ -category $\mathcal{C}_1 = \text{Ind}_\kappa^\lambda(\mathcal{C}_0)$, which is essentially small by virtue of Variant 9.3.3.3. $\square$

06KB **Corollary 9.4.6.6.** *Let $\mathcal{C}$ be an ∞ -category which is $\aleph_0$ -accessible. Then $\mathcal{C}$ is κ -accessible for every small regular cardinal κ .*

Proof. Combine Proposition 9.4.6.5 with Example 9.1.7.10. $\square$

06KC **Corollary 9.4.6.7.** *Let $\kappa \leq \lambda$ be small regular cardinals and let $\mathcal{C}$ be an ∞ -category which is κ -accessible. Then $\mathcal{C}$ admits small λ -filtered colimits, and the full subcategory $\mathcal{C}_{<\lambda}$ spanned by the λ -compact objects is essentially small.*

Proof. Enlarging λ if necessary, we may assume that $\kappa \trianglelefteq \lambda$ (see Proposition 9.1.7.8). In this case, $\mathcal{C}$ is λ -accessible (Proposition 9.4.6.5), so the desired result follows from Proposition 9.4.6.2. $\square$

06KD **Remark 9.4.6.8.** In the situation of Corollary 9.4.6.7, the ∞ -category $\mathcal{C}$ is generally not essentially small. However, it can be written as a directed union $\bigcup_{\lambda \geq \kappa} \mathcal{C}_{<\lambda}$ of essentially small subcategories $\mathcal{C}_{<\lambda}$, where λ ranges over all small regular cardinals satisfying $\lambda \geq \kappa$. In other words, every object $X \in \mathcal{C}$ is λ -compact for some small regular cardinal $\lambda \geq \kappa$. To prove this, we observe that X can be realized as the colimit of small κ -filtered diagram $\mathcal{K} \rightarrow \mathcal{C}_{<\kappa}$; we can then take $\lambda \geq \kappa$ to be any small regular cardinal for which $\mathcal{K}$ is λ -small (Proposition 9.2.5.23).

06KE **Warning 9.4.6.9.** Let $\kappa \leq \lambda$ be small regular cardinals. In general, an ∞ -category $\mathcal{C}$ which is κ -accessible need not be λ -accessible: in other words, the hypothesis $\kappa \trianglelefteq \lambda$ of Proposition 9.4.6.5 cannot be omitted (see Warning 9.3.6.6).

06KF **Definition 9.4.6.10.** Let $\mathcal{C}$ be an ∞ -category. We say that $\mathcal{C}$ is *accessible* if it is κ -accessible for some small regular cardinal κ .

06KG **Warning 9.4.6.11.** The terminology of Definition 9.4.6.10 is potentially confusing. By definition, if an ∞ -category $\mathcal{C}$ is κ -accessible for some small regular cardinal κ , then $\mathcal{C}$ is κ -compactly generated. However, the assumption that $\mathcal{C}$ is accessible does not guarantee that it is compactly generated, only that it is κ -compactly generated for *some* small regular cardinal κ .

Example 9.4.6.12. An ordinary category $\mathcal{C}$ is accessible (in the sense of Definition 9.4.0.1) 06KH if and only if the nerve $N_\bullet(\mathcal{C})$ is an accessible ∞ -category (in the sense of Definition 9.4.6.10).

Example 9.4.6.13. The ∞ -categories $\mathcal{S}$ and $\mathcal{QC}$ are accessible: in fact, they are $\aleph_0$ - 06KJ accessible (see Propositions 9.3.2.17 and 9.3.2.21), and are therefore κ -accessible for *every* small regular cardinal κ (Corollary 9.4.6.6).

Remark 9.4.6.14. Following the convention of Remark 4.7.0.5, an ∞ -category is essentially 06KK small if it is essentially Ω -small, where Ω is some fixed inaccessible cardinal. An accessible ∞ -category $\mathcal{C}$ need not satisfy this condition. However, it follows from Corollary 9.3.3.2 that $\mathcal{C}$ is locally Ω -small and essentially Ω^+ -small. Moreover, $\mathcal{C}$ admits small κ -filtered colimits for some small regular cardinal κ (and therefore for every small regular cardinal $\lambda \geq \kappa$). In particular, $\mathcal{C}$ is idempotent-complete (Example 9.1.1.9).

Warning 9.4.6.15. Let $\kappa \leq \lambda$ be regular cardinals, where λ is uncountable, and let $\mathcal{C}$ be 06KL an ∞ -category which is (κ, λ) -accessible. If λ is not strongly inaccessible, then $\mathcal{C}$ need not be locally λ -small. However, the morphism $\mathrm{Hom}_{\mathcal{C}}(X, Y)$ is essentially λ -small whenever the object $X \in \mathcal{C}$ is (κ, λ) -compact. This follows immediately from the definition if Y is (κ, λ) -compact, and follows in general from the observation that the functor $\mathrm{Hom}_{\mathcal{C}}(X, \bullet)$ is (κ, λ) -finitary.

Proposition 9.4.6.16. Let $\mathcal{C}$ be an accessible ∞ -category. Then there are arbitrarily large 06KM (small) regular cardinals λ for which $\mathcal{C}$ is λ -accessible.

Proof. Since $\mathcal{C}$ is accessible, it is κ -accessible for some small regular cardinal κ . Combining Propositions 9.4.6.5 and 9.1.7.8, we conclude that $\mathcal{C}$ is λ -accessible for every small regular cardinal λ of exponential cofinality $\geq \kappa$ (for example, every cardinal of the form $(\mu^\kappa)^+$). $\square$

Warning 9.4.6.17. Let $\mathcal{C}$ be an accessible ∞ -category. It is generally not true that $\mathcal{C}$ is 06KN λ -accessible for all sufficiently large regular cardinals λ (see Warning 9.4.6.9).

Variant 9.4.6.18. Suppose we are given a small collection of accessible ∞ -categories $\{\mathcal{C}_i\}_{i \in I}$. 06KP Then there are arbitrarily large (small) regular cardinals λ for which each $\mathcal{C}_i$ is λ -accessible.

Corollary 9.4.6.19. Let $\{\mathcal{C}_i\}_{i \in I}$ be a small collection of accessible ∞ -categories. Then the 06KQ product $\prod_{i \in I} \mathcal{C}_i$ is also accessible.

Proof. Using Variant 9.4.6.18, we can choose a small regular cardinal λ such I is λ -small and each $\mathcal{C}_i$ is λ -accessible. In this case, Remark 9.4.6.4 implies that $\prod_{i \in I} \mathcal{C}_i$ is λ -accessible. $\square$

Corollary 9.4.6.20. Let κ be a small regular cardinal. Then an ∞ -category $\mathcal{C}$ is κ -accessible 06KR if and only if it is accessible and κ -compactly generated.

Proof. Assume that $\mathcal{C}$ is both accessible and κ -compactly generated; we wish to show that it is κ -accessible (the reverse implication is immediate from the definitions). By virtue of Proposition 9.4.6.2, it will suffice to show that the full subcategory $\mathcal{C}_{<\kappa} \subseteq \mathcal{C}$ spanned by the κ -compact objects is essentially small. Using Proposition 9.4.6.16, we can choose a regular cardinal $\lambda \geq \kappa$ such that $\mathcal{C}$ is λ -accessible. Then the ∞ -category $\mathcal{C}_{<\lambda}$ is essentially small, so the full subcategory $\mathcal{C}_{<\kappa} \subseteq \mathcal{C}_{<\lambda}$ has the same property. $\square$

06KS Proposition 9.4.6.21. *Let $\mathcal{C}$ be an essentially small ∞ -category. Then $\mathcal{C}$ is accessible if and only if it is idempotent-complete.*

Our proof of Proposition 9.4.6.21 is based on the following elementary set-theoretic observation:

06KT Lemma 9.4.6.22. *Let $\kappa < \lambda$ be infinite cardinals, let $(A, \leq)$ be a λ -directed partially ordered set, and suppose we are given a diagram of κ -small sets*

$$(A, \leq) \rightarrow \mathbf{Set}_{<\kappa} \quad (\alpha \in A) \mapsto X_\alpha.$$

Then the colimit $X = \varinjlim_{\alpha \in A} X_\alpha$ is also κ -small.

Proof. Assume otherwise. Then there exists a subset $Y \subseteq X$ having cardinality κ . For each $y \in Y$, we can choose an index $\alpha_y \in A$ such that y is the image of some element $\tilde{y} \in X_{\alpha_y}$. Since Y is λ -small and $(A, \leq)$ is λ -directed, the set $\{\alpha_y : y \in Y\}$ has an upper bound α in A . It follows that Y is contained in the image of the map $X_\alpha \rightarrow X$, contradicting our assumption that X_α is κ -small. $\square$

Lemma 9.4.6.22 has a homotopy-theoretic counterpart:

06KU Lemma 9.4.6.23. *Let $\kappa < \lambda \leq \mu$ be uncountable regular cardinals, let $\mathcal{K}$ be an ∞ -category which is μ -small and λ -filtered, and suppose we are given a diagram*

$$\mathcal{F} : \mathcal{K} \rightarrow \mathcal{S}_{<\mu}.$$

Assume that, for each $K \in \mathcal{K}$, the Kan complex $\mathcal{F}(K)$ is essentially κ -small. Then the colimit $\varinjlim(\mathcal{F})$ is also essentially κ -small.

Proof. Enlarging μ if necessary, we may assume that $\lambda \leq \mu$. In this case, Theorem 9.1.8.7 guarantees the existence of a right cofinal functor $N_\bullet(A) \rightarrow \mathcal{K}$, where $(A, \leq)$ is a μ -small λ -directed partially ordered set. By virtue of Corollary 5.6.5.18, we may assume that $\mathcal{F}$ is obtained from (strictly) commutative diagram of Kan complexes

$$(A, \leq) \rightarrow \mathbf{Kan} \quad (\alpha \in A) \mapsto X_\alpha.$$

In this case, we can use Variant 9.1.6.4 to identify the colimit $\varinjlim(\mathcal{F})$ (formed in the ∞ -category $\mathcal{S}_{<\mu}$) with the colimit $X = \varinjlim_{\alpha} X_{\alpha}$ (formed in the ordinary category of Kan complexes). We will complete the proof by showing that X is essentially κ -small.

It follows from Lemma 9.4.6.22 that the set of connected components $\pi_0(X)$ is κ -small. By virtue of Proposition 4.7.7.1, it will suffice to show that for every vertex $x \in X$ and every integer $n > 0$, the homotopy group $G = \pi_n(X, x)$ is κ -small. Choose an index $\alpha \in A$ such that x lifts to a vertex $x_{\alpha} \in X_{\alpha}$. For each $\beta \geq \alpha$, let x_{β} denote the image of x_{α} in the Kan complex X_{β} . Then G can be identified with the λ -directed colimit $\varinjlim_{\beta \geq \alpha} \pi_n(X_{\beta}, x_{\beta})$, which is κ -small by virtue of Lemma 9.4.6.22. $\square$

Proposition 9.4.6.24. *Let $\kappa < \lambda \leq \mu$ be uncountable regular cardinals and let $\mathcal{C}$ be an ∞ -category which is essentially λ -small and locally κ -small. Then the canonical map $h_{\bullet} : \mathcal{C} \rightarrow \text{Ind}_{\lambda}^{\mu}(\mathcal{C})$ exhibits $\text{Ind}_{\lambda}^{\mu}(\mathcal{C})$ as an idempotent-completion of $\mathcal{C}$.* 06KV

Proof. By virtue of Theorem 9.3.4.14, we can identify $\text{Ind}_{\lambda}^{\mu}(\mathcal{C})$ with the full subcategory of $\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}_{<\mu})$ spanned by those functors which are λ -flat and $h_{\bullet}$ with the covariant Yoneda embedding $C \mapsto \text{Hom}_{\mathcal{C}}(\bullet, C)$. To complete the proof, we must show that every λ -flat functor $\mathcal{F} : \mathcal{C}^{\text{op}} \rightarrow \mathcal{S}_{<\mu}$ is retract of a representable functor. Equivalently, we must show that for each object $C \in \mathcal{C}$, the Kan complex $\mathcal{F}(C)$ is essentially λ -small (Remark 9.3.4.12). In fact, we claim that $\mathcal{F}(C)$ is essentially κ -small. To prove this, we can use Lemma 9.3.4.19 to realize $\mathcal{F}(C)$ as the colimit of a μ -small λ -filtered diagram

$$\mathcal{K} \rightarrow \mathcal{C} \xrightarrow{\text{Hom}_{\mathcal{C}}(C, \bullet)} \mathcal{S}_{<\mu},$$

which is κ -small by virtue of Lemma 9.4.6.23 (since $\mathcal{C}$ is locally κ -small). $\square$

Corollary 9.4.6.25. *Let $\kappa < \lambda$ be uncountable regular cardinals and let $\mathcal{C}$ be an idempotent-complete ∞ -category which is essentially λ -small and locally κ -small. Then:* 06KW

- (1) *The ∞ -category $\mathcal{C}$ admits λ -filtered colimits.*
- (2) *Every functor of ∞ -categories $F : \mathcal{C} \rightarrow \mathcal{D}$ preserves λ -filtered colimits.*

Proof. Let $\mathcal{K}$ be a λ -filtered ∞ -category, and fix a regular cardinal $\mu \geq \lambda$ such that $\mathcal{K}$ is μ -small. Applying Proposition 9.4.6.24, we see that the tautological map $h : \mathcal{C} \rightarrow \text{Ind}_{\lambda}^{\mu}(\mathcal{C})$ is an equivalence of ∞ -categories. Since $\text{Ind}_{\lambda}^{\mu}(\mathcal{C})$ admits $\mathcal{K}$ -indexed colimits, it follows that $\mathcal{C}$ admits $\mathcal{K}$ -indexed colimits. We will complete the proof by showing that every functor of ∞ -categories $F : \mathcal{C} \rightarrow \mathcal{D}$ preserves $\mathcal{K}$ -indexed colimits. Enlarging $\mathcal{D}$ if necessary, we may assume that it admits μ -small λ -filtered colimits (for example, we can replace $\mathcal{D}$ by the ∞ -category $\text{Ind}_{\lambda}^{\mu}(\mathcal{D})$). In this case, F admits an $\text{Ind}_{\lambda}^{\mu}$ -extension $\widehat{F} : \text{Ind}_{\lambda}^{\mu}(\mathcal{C}) \rightarrow \mathcal{D}$ (Definition 9.3.1.12). Then $\widehat{F}$ preserves $\mathcal{K}$ -indexed colimits and F is isomorphic to the composite functor $\widehat{F} \circ h$. Since h is an equivalence of ∞ -categories, it follows that F also preserves $\mathcal{K}$ -indexed colimits. $\square$

Proof of Proposition 9.4.6.21. Let $\mathcal{C}$ be an essentially small ∞ -category which is idempotent-complete; we wish to show that $\mathcal{C}$ is accessible (the reverse implication follows from Remark 9.4.6.14). Let κ be a small uncountable regular cardinal for which $\mathcal{C}$ is locally κ -small, and let $\lambda > \kappa$ be a small regular cardinal for which $\mathcal{C}$ is essentially λ -small. Applying Proposition 9.4.6.24, we deduce that $\mathcal{C}$ can be identified with an Ind_λ -completion of itself. In particular, $\mathcal{C}$ is λ -accessible. $\square$

9.4.7 Accessible Functors

06KX We now study functors between accessible ∞ -categories.

06KY **Definition 9.4.7.1.** Let $\mathcal{C}$ and $\mathcal{D}$ be accessible ∞ -categories. We say that a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is *accessible* if there exists a small regular cardinal κ such that F preserves small κ -filtered colimits.

06KZ **Remark 9.4.7.2.** In the situation of Definition 9.4.7.1, if the functor F preserves small κ -filtered colimits, then it also preserves small λ -filtered colimits for every small regular cardinal $\lambda \geq \kappa$. In particular, we can arrange that the ∞ -category $\mathcal{C}$ is λ -accessible (Proposition 9.4.6.16), so that $\mathcal{C}$ is an Ind_λ -completion of the full subcategory $\mathcal{C}_{<\lambda}$ spanned by the λ -compact objects, and F is an Ind_λ -extension of the functor $F_{<\lambda} = F|_{\mathcal{C}_{<\lambda}}$ (Definition 9.3.1.12).

06L0 **Example 9.4.7.3.** Let $\mathcal{C}$ and $\mathcal{D}$ be accessible ∞ -categories. If $\mathcal{C}$ is essentially small, then every functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is accessible. See Corollary 9.4.6.25.

06L1 **Example 9.4.7.4.** Let $\mathcal{C}$ be an accessible ∞ -category and let $\{\mathcal{D}_i\}_{i \in I}$ be a collection of accessible ∞ -categories indexed by a small set I , so that the product $\mathcal{D} = \prod_{i \in I} \mathcal{D}_i$ is also an accessible ∞ -category (Corollary 9.4.6.19). Then a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is accessible if and only if, for each $i \in I$, the composition $\mathcal{C} \xrightarrow{F} \mathcal{D} \rightarrow \mathcal{D}_i$ is accessible.

06L2 **Example 9.4.7.5.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be an equivalence of ∞ -categories. Then $\mathcal{C}$ is accessible if and only if $\mathcal{D}$ is accessible. If these conditions are satisfied, then F is an accessible functor. In particular, for every accessible ∞ -category $\mathcal{C}$, the identity functor $\text{id}_{\mathcal{C}} : \mathcal{C} \rightarrow \mathcal{C}$ is accessible.

06L3 **Remark 9.4.7.6** (Retracts). Let $\mathcal{C}$ and $\mathcal{D}$ be accessible ∞ -categories and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be an accessible functor. If another functor $G : \mathcal{C} \rightarrow \mathcal{D}$ is a retract of F (in the ∞ -category $\text{Fun}(\mathcal{C}, \mathcal{D})$), then G is also accessible. In particular, if two functors $F, G : \mathcal{C} \rightarrow \mathcal{D}$ are isomorphic, then F is accessible if and only if G is accessible.

06L4 **Remark 9.4.7.7** (Composition). Let $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ be accessible ∞ -categories. If $F : \mathcal{C} \rightarrow \mathcal{D}$ and $G : \mathcal{D} \rightarrow \mathcal{E}$ are accessible functors, then the composite functor $(G \circ F) : \mathcal{C} \rightarrow \mathcal{E}$ is also accessible.

Notation 9.4.7.8. Following the convention of Remark 4.7.0.5, an ∞ -category is essentially small if it is essentially Ω -small, where Ω denotes some fixed strongly inaccessible cardinal. In this case, every accessible ∞ -category $\mathcal{C}$ is essentially Ω^+ -small (Remark 9.4.6.14). We let $\mathcal{QC}^{\text{Acc}}$ denote the subcategory of $\mathcal{QC}_{<\Omega^+}$ whose objects are accessible ∞ -categories and whose morphisms are accessible functors. We will refer to $\mathcal{QC}^{\text{Acc}}$ as *the ∞ -category of accessible ∞ -categories*. 06L5

Proposition 9.4.7.9. *Let $\mathcal{C}$ and $\mathcal{D}$ be accessible ∞ -categories and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor. The following conditions are equivalent:* 06L6

- (1) *The functor F is accessible: that is, there exists a small regular cardinal κ such that F preserves small κ -filtered colimits.*
- (2) *There exists a small regular cardinal λ such that $\mathcal{C}$ and $\mathcal{D}$ are λ -accessible and the functor F is λ -compact (see Variant 9.4.2.2).*

Proof. Assume that F is accessible; we will show that condition (2) is satisfied (the converse is immediate from the definitions). Using Remark 9.4.7.2, we can choose a small regular cardinal κ for which $\mathcal{C}$ and $\mathcal{D}$ are κ -accessible and the functor F is κ -finitary. Let $\mathcal{C}_{<\kappa}$ be the full subcategory of $\mathcal{C}$ spanned by the κ -compact objects. It follows from Proposition 9.4.6.2 that $\mathcal{C}_{<\kappa}$ is essentially small. Using Remark 9.4.6.8, we can choose a small regular cardinal $\lambda \geq \kappa$ such that $F(\mathcal{C}_{<\kappa}) \subseteq \mathcal{D}_{<\lambda}$: that is, F carries κ -compact objects of $\mathcal{C}$ to λ -compact objects of $\mathcal{D}$. Enlarging λ if necessary, we may assume that $\kappa \leq \lambda$ (see Proposition 9.1.7.8). We will complete the proof by showing that the functor F is λ -compact. Since the functor F is κ -finitary, it is also λ -finitary. It will therefore suffice to show that for every λ -compact object $C \in \mathcal{C}$, the image $F(C) \in \mathcal{D}$ is also λ -compact. Using Corollary 9.3.6.7, we can realize C as the colimit of a λ -small κ -filtered diagram $G : \mathcal{K} \rightarrow \mathcal{C}_{<\kappa} \subseteq \mathcal{C}$. Since the functor F is κ -finitary, the object $F(C)$ is a colimit of the composite functor

$$\mathcal{K} \xrightarrow{G} \mathcal{C}_{<\kappa} \xrightarrow{F} \mathcal{D}_{<\lambda} \subseteq \mathcal{D},$$

and is therefore λ -compact by virtue of Corollary 9.2.5.24. $\square$

Remark 9.4.7.10. Let $F_0 : \mathcal{C}_0 \rightarrow \mathcal{D}_0$ be a functor between essentially small ∞ -categories. For any small regular cardinal λ , the induced functor 06L7

$$\text{Ind}_\lambda(F_0) : \text{Ind}_\lambda(\mathcal{C}_0) \rightarrow \text{Ind}_\lambda(\mathcal{D}_0)$$

is an accessible functor between accessible ∞ -categories. Proposition 9.4.7.9 asserts the converse: up to equivalence, every accessible functor can be obtained in this way.

06L8 **Remark 9.4.7.11.** In the situation of Proposition 9.4.7.9, let λ be a small regular cardinal for which $\mathcal{C}$ and $\mathcal{D}$ are λ -accessible and the functor F is λ -compact. Then, for every small regular cardinal μ satisfying $\lambda \leq \mu$, the ∞ -categories $\mathcal{C}$ and $\mathcal{D}$ are μ -accessible and the functor F is μ -compact. In particular, there are arbitrarily large (small) regular cardinals μ which satisfy this condition. See Propositions 9.4.6.5 and 9.4.2.18.

06L9 **Variant 9.4.7.12.** Let $\{F_i : \mathcal{C}_i \rightarrow \mathcal{D}_i\}_{i \in I}$ be a small collection of accessible functors between accessible ∞ -categories. Then there exists a small regular cardinal λ such that each of the ∞ -categories $\mathcal{C}_i$ and $\mathcal{D}_i$ is λ -accessible, and each of the functors F_i is λ -compact. Moreover, λ can be chosen arbitrarily large.

06LA **Example 9.4.7.13.** Let $\mathcal{C}$ be an accessible ∞ -category. Then, for every object $C \in \mathcal{C}$, the corepresentable functor

$$\mathrm{Hom}_{\mathcal{C}}(C, \bullet) : \mathcal{C} \rightarrow \mathcal{S}$$

is accessible. This is a reformulation of Remark 9.4.6.8.

06LB **Proposition 9.4.7.14.** *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, where $\mathcal{C}$ and $\mathcal{D}$ are accessible. The following conditions are equivalent:*

(1) *The functor F is accessible.*

(2) *For every object $D \in \mathcal{D}$, the composite functor*

$$\mathcal{C} \xrightarrow{F} \mathcal{D} \xrightarrow{\mathrm{Hom}_{\mathcal{D}}(D, \bullet)} \mathcal{S}$$

is accessible.

Proof. The implication (1) $\Rightarrow$ (2) follows from Example 9.4.7.13 and Remark 9.4.7.7. Conversely, suppose that condition (2) is satisfied. Since $\mathcal{D}$ is accessible, it admits a dense full subcategory $\mathcal{D}_0 \subseteq \mathcal{D}$ which is essentially small (for example, if $\mathcal{D}$ is κ -accessible, we can take $\mathcal{D}_0$ to be the full subcategory spanned by the κ -compact objects). Applying Proposition 8.4.1.8, we see that the restricted Yoneda embedding

$$h : \mathcal{D} \rightarrow \mathrm{Fun}(\mathcal{D}_0^{\mathrm{op}}, \mathcal{S}) \quad Y \mapsto \mathrm{Hom}_{\mathcal{D}}(\bullet, Y)$$

is fully faithful. It will therefore suffice to show that there exists a small regular cardinal λ for which the composite functor $h \circ F$ preserves small λ -filtered colimits. By virtue of Proposition 7.1.8.2, this is equivalent to the requirement that the composite functor $\mathcal{C} \xrightarrow{F} \mathcal{D} \xrightarrow{\mathrm{Hom}_{\mathcal{D}}(D, \bullet)} \mathcal{S}$ preserves small filtered colimits for each $D \in \mathcal{D}_0$. The existence of λ follows by combining (2) with our assumption that $\mathcal{D}_0$ is essentially small. $\square$

06LC **Corollary 9.4.7.15** (Adjoint Accessibility). *Let $\mathcal{C}$ and $\mathcal{D}$ be accessible ∞ -categories and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor which admits a right adjoint $G : \mathcal{D} \rightarrow \mathcal{C}$. Then F and G are accessible functors.*

Proof. The functor F preserves all colimits which exist in $\mathcal{C}$ (Corollary 7.1.4.23) and is therefore accessible. To show that G is accessible, it will suffice to show that for each object $C \in \mathcal{C}$, the composite functor

$$\mathcal{D} \xrightarrow{G} \mathcal{C} \xrightarrow{\mathrm{Hom}_{\mathcal{C}}(C, \bullet)} \mathcal{S}$$

is accessible (Proposition 9.4.7.14). Since G is right adjoint to F , this composite functor is corepresented by the object $F(C) \in \mathcal{D}$, so the desired result follows from Example 9.4.7.13. $\square$

9.4.8 Stability Properties of Accessible ∞ -Categories

We now record some stability properties for the collection of accessible ∞ -categories. 06LD

Proposition 9.4.8.1 (Accessibility of Diagram ∞ -Categories). *Let K be a small simplicial set. If $\mathcal{C}$ is an accessible ∞ -category, then the ∞ -category $\mathrm{Fun}(K, \mathcal{C})$ is also accessible.* 06LE

Proof. Fix a small regular cardinal κ for which $\mathcal{C}$ admits small κ -filtered colimits (this condition is satisfied, for example, if $\mathcal{C}$ is accessible). Using Proposition 9.4.6.16, we can choose a small regular cardinal $\lambda > \kappa$ such that K is λ -small and $\mathcal{C}$ is λ -accessible. We will complete the proof by showing that $\mathrm{Fun}(K, \mathcal{C})$ is λ -accessible. Let $\mathcal{C}_{<\lambda}$ be the full subcategory of $\mathcal{C}$ spanned by the λ -compact objects. Since $\mathcal{C}_{<\lambda}$ is κ -sequentially cocomplete, Corollary 9.4.5.14 implies that the ∞ -category $\mathrm{Fun}(K, \mathcal{C})$ is λ -compactly generated, and that the full subcategory of λ -compact objects coincides with $\mathrm{Fun}(K, \mathcal{C}_{<\lambda})$. To complete the proof, it will suffice to show that the ∞ -category $\mathrm{Fun}(K, \mathcal{C}_{<\lambda})$ is essentially small. This follows from Remark 4.7.5.11, since $\mathcal{C}_{<\lambda}$ and K are essentially small. $\square$

Remark 9.4.8.2. In the situation of Proposition 9.4.8.1, suppose we are given another accessible ∞ -category $\mathcal{D}$ and a functor $T : \mathcal{D} \rightarrow \mathrm{Fun}(K, \mathcal{C})$. Then T is accessible if and only if, for every vertex $x \in K$, the composition $\mathcal{D} \xrightarrow{T} \mathrm{Fun}(K, \mathcal{C}) \xrightarrow{\mathrm{ev}_x} \mathrm{Fun}(\{x\}, \mathcal{C}) \simeq \mathcal{C}$ is an accessible functor. See Proposition 7.1.8.2. 06LF

Proposition 9.4.8.3 (Accessibility of Oriented Fiber Products). *Let $\mathcal{C}_-$, $\mathcal{C}_+$, and $\mathcal{C}$ be accessible ∞ -categories and suppose we are given accessible functors $F_- : \mathcal{C}_- \rightarrow \mathcal{C}$ and $F_+ : \mathcal{C}_+ \rightarrow \mathcal{C}$. Then the oriented fiber product $\mathcal{C}_{\pm} = \mathcal{C}_- \tilde{\times}_{\mathcal{C}} \mathcal{C}_+$ is accessible.* 06LG

Proof. Using Variant 9.4.7.12, we can choose a small regular cardinal κ such that $\mathcal{C}_-$, $\mathcal{C}_+$ and $\mathcal{C}$ are κ -accessible and the functors F_- and F_+ are κ -compact. Applying Corollary 9.4.3.4, we deduce that $\mathcal{C}_{\pm}$ is κ -compactly generated. Let $\mathcal{C}^0 \subseteq \mathcal{C}$ be the full subcategory spanned by the κ -compact objects, and define $\mathcal{C}_-^0$, $\mathcal{C}_+^0$, and $\mathcal{C}_{\pm}^0$ similarly. We will complete the proof by showing that the ∞ -category $\mathcal{C}_{\pm}^0$ is essentially small. By assumption, the ∞ -categories $\mathcal{C}_-^0$, $\mathcal{C}_+^0$, and $\mathcal{C}^0$ are essentially small. Using Corollary 9.4.3.4, we can identify $\mathcal{C}_{\pm}^0$ with the oriented fiber product $\mathcal{C}_-^0 \tilde{\times}_{\mathcal{C}^0} \mathcal{C}_+^0$, so the desired result is a special case of Proposition 4.7.5.15. $\square$

06LH **Remark 9.4.8.4.** In the situation of Proposition 9.4.8.3, suppose we are given another accessible ∞ -category $\mathcal{D}$ and a functor

$$T : \mathcal{D} \rightarrow \mathcal{C}_{\pm} = \mathcal{C}_{-} \tilde{\times}_{\mathcal{C}} \mathcal{C}_{+}.$$

Then T is accessible if and only if the components $T_{-} : \mathcal{D} \rightarrow \mathcal{C}_{-}$ and $T_{+} : \mathcal{D} \rightarrow \mathcal{C}_{+}$ are accessible functors. See Proposition 7.1.9.4.

06LJ **Corollary 9.4.8.5** (Accessibility of Slices). *Let $\mathcal{C}$ be an accessible ∞ -category and let $F : K \rightarrow \mathcal{C}$ be a small diagram. Then the slice and coslice ∞ -categories $\mathcal{C}_{/F}$ and $\mathcal{C}_{F/}$ are accessible.*

Proof. Combine Propositions 9.4.8.1 and 9.4.8.3 with the equivalences

$$\mathcal{C}_{/F} \hookrightarrow \mathcal{C} \tilde{\times}_{\mathrm{Fun}(K, \mathcal{C})} \{F\} \quad \mathcal{C}_{F/} \hookrightarrow \{F\} \tilde{\times}_{\mathrm{Fun}(K, \mathcal{C})} \mathcal{C}$$

supplied by Theorem 4.6.4.19. □

06LK **Remark 9.4.8.6.** In the situation of Corollary 9.4.8.5, suppose we are given another accessible ∞ -category $\mathcal{D}$ and a functor $T : \mathcal{D} \rightarrow \mathcal{C}_{/F}$. Then T is accessible if and only if the composition $\mathcal{D} \xrightarrow{T} \mathcal{C}_{/F} \rightarrow \mathcal{C}$ is accessible (see Remark 9.4.8.4). Similarly, a functor $T' : \mathcal{D} \rightarrow \mathcal{C}_{F/}$ is accessible if and only if the composition $\mathcal{D} \xrightarrow{T'} \mathcal{C}_{F/} \rightarrow \mathcal{C}$ is accessible.

06LL **Example 9.4.8.7.** Let $\mathcal{C}$ be an accessible ∞ -category. Then, for every object $X \in \mathcal{C}$, the ∞ -categories $\mathcal{C}_{X/}$ and $\mathcal{C}_{/X}$ are also accessible.

06LM **Proposition 9.4.8.8** (Accessibility of Homotopy Fiber Products). *Let $\mathcal{C}_{-}$, $\mathcal{C}_{+}$, and $\mathcal{C}$ be accessible ∞ -categories and suppose we are given accessible functors $F_{-} : \mathcal{C}_{-} \rightarrow \mathcal{C}$ and $F_{+} : \mathcal{C}_{+} \rightarrow \mathcal{C}$. Then the homotopy fiber product $\mathcal{C}_{\pm} = \mathcal{C}_{-} \times_{\mathcal{C}}^{\mathrm{h}} \mathcal{C}_{+}$ is accessible.*

Proof. Fix a small regular cardinal κ such that $\mathcal{C}_{-}$ and $\mathcal{C}_{+}$ admit small κ -filtered colimits which are preserved by the functors F_{-} and F_{+} . Using Variant 9.4.7.12, we can choose a small regular cardinal $\lambda > \kappa$ such that $\mathcal{C}_{-}$, $\mathcal{C}_{+}$ and $\mathcal{C}$ are λ -accessible and the functors F_{-} and F_{+} are λ -compact. Apply Corollary 9.4.4.10, we deduce that the ∞ -category $\mathcal{C}_{\pm}$ is λ -compactly generated. Let $\mathcal{C}^0 \subseteq \mathcal{C}$ be the full subcategory spanned by the λ -compact objects, and define $\mathcal{C}_{-}^0$, $\mathcal{C}_{+}^0$, and $\mathcal{C}_{\pm}^0$ similarly. We will complete the proof by showing that the ∞ -category $\mathcal{C}_{\pm}^0$ is essentially small. By assumption, the ∞ -categories $\mathcal{C}_{-}^0$, $\mathcal{C}_{+}^0$, and $\mathcal{C}^0$ are essentially small. Using Corollary 9.4.4.10, we can identify $\mathcal{C}_{\pm}^0$ with the homotopy fiber product $\mathcal{C}_{-}^0 \times_{\mathcal{C}^0}^{\mathrm{h}} \mathcal{C}_{+}^0$, so the desired result is a special case of Corollary 4.7.5.16. □

06LN **Remark 9.4.8.9.** In the situation of Proposition 9.4.8.8, suppose we are given another accessible ∞ -category $\mathcal{D}$ and a functor

$$T : \mathcal{D} \rightarrow \mathcal{C}_{\pm} = \mathcal{C}_{-} \times_{\mathcal{C}}^{\mathrm{h}} \mathcal{C}_{+}.$$

Then T is accessible if and only if the components $T_- : \mathcal{D} \rightarrow \mathcal{C}_-$ and $T_+ : \mathcal{D} \rightarrow \mathcal{C}_+$ are accessible functors. See Corollary 7.1.9.7.

Corollary 9.4.8.10. *Suppose we are given a categorical pullback square of ∞ -categories* 06LP

$$\begin{array}{ccc} \mathcal{C}_\pm & \xrightarrow{G_+} & \mathcal{C}_+ \\ \downarrow G_- & & \downarrow F_+ \\ \mathcal{C}_- & \xrightarrow{F_-} & \mathcal{C}. \end{array}$$

Assume that $\mathcal{C}_-$, $\mathcal{C}_+$, and $\mathcal{C}$ are accessible ∞ -categories and that F_- and F_+ are accessible functors. Then the ∞ -category $\mathcal{C}_\pm$ and the functors G_- and G_+ are also accessible. Moreover, if $\mathcal{D}$ is another accessible ∞ -category, then a functor $T : \mathcal{D} \rightarrow \mathcal{C}_\pm$ is accessible if and only if the compositions $G_- \circ T$ and $G_+ \circ T$ are accessible.

Proof. This is a reformulation of Proposition 9.4.8.8 (together with Remark 9.4.8.9). $\square$

Let $\mathcal{QC}^{\text{Acc}}$ denote the ∞ -category whose objects are accessible ∞ -categories and whose morphisms are accessible functors (see Notation 9.4.7.8).

Corollary 9.4.8.11 (Limits of Accessible ∞ -Categories). *The ∞ -category $\mathcal{QC}^{\text{Acc}}$ admits small limits, which are preserved by the inclusion functor $\iota : \mathcal{QC}^{\text{Acc}} \hookrightarrow \mathcal{QC}_{<\Omega^+}$. Here Ω denotes the strongly inaccessible cardinal of Remark 4.7.0.5.* 06LQ

Proof. By virtue of Proposition 7.6.6.14 (together with Remarks 7.6.6.15 and Exercise 7.6.6.16), it will suffice to show that the ∞ -category $\mathcal{QC}^{\text{Acc}}$ admits pullbacks and small products which are preserved by the inclusion functor ι . For pullbacks this is a reformulation of Corollary 9.4.8.10 (see Example 7.6.3.4), and for small products it follows from Corollary 9.4.6.19 and Example 9.4.7.4. $\square$

We close this section by recording a generalization of Corollary 9.4.8.11.

Definition 9.4.8.12. Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. We will say that U is *edgewise accessible* if, for every n -simplex $\sigma : \Delta^n \rightarrow \mathcal{C}$, the fiber product $\mathcal{E}_\sigma = \Delta^n \times_{\mathcal{C}} \mathcal{E}$ is an accessible ∞ -category. 06LR

Warning 9.4.8.13. Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. If U is edgewise accessible, then the ∞ -category $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is accessible for each vertex $C \in \mathcal{C}$. Beware that the converse is false in general (see Corollaries 9.4.8.23 and 9.4.8.25). However, it is sufficient to verify the accessibility of all fiber products $\Delta^n \times_{\mathcal{C}} \mathcal{E}$ for $n = 1$ (Corollary 9.4.8.21), which motivates the terminology of Definition 9.4.8.12. 06LS

- 06LT **Example 9.4.8.14.** Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an isofibration of ∞ -categories, where $\mathcal{C}$ and $\mathcal{E}$ are accessible. If U is accessible when regarded as a functor (in the sense of Definition 9.4.7.1), then it is edgewise accessible as an inner fibration (in the sense of Definition 9.4.8.12). This follows from Corollary 9.4.8.10, since every n -simplex $\sigma : \Delta^n \rightarrow \mathcal{C}$ is accessible when regarded as a functor (Example 9.4.7.3). Beware that the converse is false in general.
- 06LU **Variant 9.4.8.15.** Let κ be a small regular cardinal and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. We say that U is *edgewise κ -accessible* if, for every n -simplex $\sigma : \Delta^n \rightarrow \mathcal{C}$, the fiber product $\mathcal{E}_\sigma = \Delta^n \times_{\mathcal{C}} \mathcal{E}$ is a κ -accessible ∞ -category.
- 06LV **Remark 9.4.8.16.** Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. It follows immediately from the definitions that if U is edgewise- κ -accessible for some small regular cardinal κ , then it is edgewise accessible. The converse holds if the simplicial set $\mathcal{C}$ is small (see Variant 9.4.6.18).
- 06LW **Example 9.4.8.17.** Let $\mathcal{E}$ be an ∞ -category. Then $\mathcal{E}$ is accessible if and only if the inner fibration $U : \mathcal{E} \rightarrow \Delta^0$ is an edgewise accessible. More generally, if κ is a small regular cardinal, then $\mathcal{E}$ is κ -accessible if and only if U is edgewise κ -accessible.
- 06LX **Remark 9.4.8.18.** Suppose we are given a pullback diagram of simplicial sets

$$\begin{array}{ccc} \mathcal{E}' & \xrightarrow{\quad} & \mathcal{E} \\ \downarrow U' & & \downarrow U \\ \mathcal{C}' & \xrightarrow{\quad} & \mathcal{C} \end{array}$$

where the vertical maps are inner fibrations. If U is edgewise accessible, then U' is edgewise accessible. Similarly, if U is edgewise κ -accessible, then U' is edgewise κ -accessible.

Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. If U is edgewise κ -accessible (in the sense of Variant 9.4.8.15), then it is also κ -compactly generated (in the sense of Definition 9.4.5.2). For the converse, we have the following:

- 06LY **Proposition 9.4.8.19.** *Let κ be a small regular cardinal and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets which is κ -compactly generated. The following conditions are equivalent:*
- (1) *The inner fibration U is edgewise κ -accessible.*
 - (2) *The inner fibration U is edgewise accessible.*
 - (3) *The inner fibration U is locally small (see Variant 4.7.9.2) and, for each vertex $C \in \mathcal{C}$, the fiber $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is accessible.*

- (4) Let $\mathcal{E}' \subseteq \mathcal{E}$ be the full simplicial subset spanned by those vertices X which are κ -compact when viewed as objects of the fiber $\{U(X)\} \times_{\mathcal{C}} \mathcal{E}$. Then the inner fibration $(U|_{\mathcal{E}'} : \mathcal{E}' \rightarrow \mathcal{C})$ is essentially small (see Variant 4.7.9.2).

Proof. The implication (1) $\Rightarrow$ (2) is immediate, the implication (2) $\Rightarrow$ (3) follows from Remark 9.4.6.14 and Warning 9.4.8.13, and the implication (3) $\Rightarrow$ (4) follows from Proposition 9.4.6.2. We will complete the proof by showing that (4) implies (1). Assume that condition (4) is satisfied and choose an n -simplex $\sigma : \Delta^n \rightarrow \mathcal{C}$; we wish to show that the ∞ -category $\mathcal{E}_\sigma = \Delta^n \times_{\mathcal{C}} \mathcal{E}$ is κ -accessible. Our assumption that U is κ -compactly generated guarantees that $\mathcal{E}_\sigma$ is κ -compactly generated. Let $\mathcal{E}'_\sigma \subseteq \mathcal{E}_\sigma$ be the full subcategory spanned by the κ -compact objects. We will complete the proof by showing that $\mathcal{E}'_\sigma$ is essentially small (see Proposition 9.4.6.2). This follows from assumption (4), since $\mathcal{E}'_\sigma$ can be identified with the fiber product $\Delta^n \times_{\mathcal{C}} \mathcal{E}'$ (see the proof of Proposition 9.4.5.11). $\square$

Remark 9.4.8.20. Let κ be a small regular cardinal and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. Then U is edgewise κ -accessible if and only if it is an Ind_κ -completion of an essentially small inner fibration $U' : \mathcal{E}' \rightarrow \mathcal{C}$. Moreover, if these conditions are satisfied, then we can assume that $\mathcal{E}'$ is the full simplicial subset of $\mathcal{E}$ appearing in the statement of Proposition 9.4.8.19. See Proposition 9.4.5.10. 06LZ

Corollary 9.4.8.21. Let κ be a small regular cardinal and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets. The following conditions are equivalent: 06M0

- (1) The inner fibration U is edgewise κ -accessible.
- (2) For every edge σ of $\mathcal{C}$, the fiber product $\mathcal{E}_\sigma = \Delta^1 \times_{\mathcal{C}} \mathcal{E}$ is κ -accessible.

Proof. The implication (1) $\Rightarrow$ (2) is immediate from the definition. The converse follows by combining Propositions 9.4.8.19, 9.4.5.11, and 4.7.9.7. $\square$

Corollary 9.4.8.22. Let κ be a small regular cardinal and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a locally cartesian fibration of simplicial sets. Then U is edgewise κ -accessible if and only if the following conditions are satisfied: 06M1

- For every vertex $C \in \mathcal{C}$, the fiber $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is a κ -accessible ∞ -category.
- For every edge $e : C \rightarrow C'$ of $\mathcal{C}$, the contravariant transport functor $e^* : \mathcal{E}_{C'} \rightarrow \mathcal{E}_C$ is κ -finitary.

Proof. Combine Proposition 9.4.8.19 with Corollary 9.4.5.8 and Proposition 5.1.5.14. $\square$

Corollary 9.4.8.23. Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a locally cartesian fibration of simplicial sets. Then U is edgewise accessible if and only if the following conditions are satisfied: 06M2

- (1) For every vertex $C \in \mathcal{C}$, the fiber $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is an accessible ∞ -category.
- (2) For every edge $e : C \rightarrow C'$ of $\mathcal{C}$, the contravariant transport functor $e^* : \mathcal{E}_{C'} \rightarrow \mathcal{E}_C$ is accessible.

06M3 Corollary 9.4.8.24. *Let κ be a small regular cardinal and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a locally cocartesian fibration of simplicial sets. Then U is edgewise κ -accessible if and only if the following conditions are satisfied:*

- For every vertex $C \in \mathcal{C}$, the fiber $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is a κ -accessible ∞ -category.
- For every edge $e : C \rightarrow C'$ of $\mathcal{C}$, the covariant transport functor $e_! : \mathcal{E}_C \rightarrow \mathcal{E}_{C'}$ is κ -compact.

Proof. Combine Proposition 9.4.8.19 with Corollary 9.4.5.9 and Proposition 5.1.5.14. $\square$

06M4 Corollary 9.4.8.25. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a locally cocartesian fibration of simplicial sets. Then U is edgewise accessible if and only if the following conditions are satisfied:*

- (1) For every vertex $C \in \mathcal{C}$, the fiber $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is an accessible ∞ -category.
- (2) For every edge $e : C \rightarrow C'$ of $\mathcal{C}$, the covariant transport functor $e_! : \mathcal{E}_C \rightarrow \mathcal{E}_{C'}$ is accessible.

Proof. Combine Corollary 9.4.8.24 with Variant 9.4.7.12. $\square$

06M5 Example 9.4.8.26. Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a cocartesian fibration of simplicial sets. Corollary 9.4.8.25 implies that U is edgewise accessible (in the sense of Definition 9.4.8.12) if and only if the covariant transport representation $\mathrm{Tr}_{\mathcal{E}/\mathcal{C}}$ takes values in the ∞ -category $\mathcal{QC}^{\mathrm{Acc}}$ whose objects are accessible ∞ -categories and whose morphisms are accessible functors (Notation 9.4.7.8). Similarly, Corollary 9.4.8.23 guarantees that a cartesian fibration is edgewise accessible if and only if its contravariant transport representation takes values in $\mathcal{QC}^{\mathrm{Acc}}$.

06M6 Example 9.4.8.27. Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets which is both locally cartesian and locally cocartesian. Then U is edgewise accessible if and only if each fiber $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is an accessible ∞ -category. This follows by combining Corollary 9.4.8.23 (or Corollary 9.4.8.25) with Corollary 9.4.7.15.

06M7 Proposition 9.4.8.28. *Let λ be a small regular cardinal and let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets which is edgewise λ -accessible. Suppose that $\mathcal{C}$ is small and that there exists a regular cardinal $\kappa < \lambda$ such that U is κ -sequentially cocomplete. Then the ∞ -category of sections $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ is λ -accessible.*

Proof. Let $\mathcal{E}' \subseteq \mathcal{E}$ be the full simplicial subset spanned by those vertices $X \in \mathcal{E}$ which are λ -compact when viewed as objects of the fiber $\{U(X)\} \times_{\mathcal{C}} \mathcal{E}$. Then U restricts to an essentially small inner fibration $U' : \mathcal{E}' \rightarrow \mathcal{C}$ (Proposition 9.4.6.2), so the ∞ -category $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E}')$ is essentially small (Variant 4.7.9.11). Applying Theorem 9.4.5.13, we see that $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ is an Ind_{λ} -completion of $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E}')$, and is therefore λ -accessible. $\square$

Corollary 9.4.8.29. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of simplicial sets which is edgewise accessible. If $\mathcal{C}$ is small, then the ∞ -category $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ is accessible.* 06M8

Proof. Using Remark 9.4.8.16, we can choose a small regular cardinal κ such that U is edgewise κ -accessible. Let λ be another small regular cardinal satisfying $\kappa \triangleleft \lambda$. Then the inner fibration U is also edgewise λ -accessible (Proposition 9.4.6.5). Applying Proposition 9.4.8.28, we conclude that $\mathrm{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ is λ -accessible. $\square$

9.5 Local Objects and Factorization Systems

9.5.1 Digression: Transfinite Composition

04KF

Let $\mathcal{C}$ be an ∞ -category and let $X : \mathbf{N}_{\bullet}(\mathbf{Z}_{\geq 0}) \rightarrow \mathcal{C}$ be a functor, which we display as a diagram 04KZ

$$X(0) \xrightarrow{f_0} X(1) \xrightarrow{f_1} X(2) \xrightarrow{f_2} X(3) \rightarrow \cdots$$

Suppose that X can be extended to a colimit diagram $\overline{X} : \mathbf{N}_{\bullet}(\mathbf{Z}_{\geq 0})^{\triangleright} \rightarrow \mathcal{C}$, carrying the cone point to an object $Y = \varinjlim(X)$. In this case, we can evaluate $\overline{X}$ on the edge $\{0\}^{\triangleright} \subseteq \mathbf{N}_{\bullet}(\mathbf{Z}_{\geq 0})^{\triangleright}$ to obtain a morphism $g : X(0) \rightarrow Y$. Heuristically, we can think of the morphism g as an “infinite composition” $\cdots f_4 \circ f_3 \circ f_2 \circ f_1 \circ f_0$. Our goal in this section is to extend this heuristic to more general well-ordered diagrams.

In what follows, we assume that the reader is familiar with the theory of ordinals (see §4.7.1 for a review). For every ordinal α , let $\mathrm{Ord}_{\leq \alpha}$ denote the linearly ordered set of ordinals which are less than or equal to α , and let $\mathrm{Ord}_{< \alpha}$ denote the subset consisting of ordinals which are strictly smaller than α .

Definition 9.5.1.1. Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$. We will say that a morphism f of $\mathcal{C}$ is a *transfinite composition of morphisms of W* if there exists an ordinal α and a functor $F : \mathbf{N}_{\bullet}(\mathrm{Ord}_{\leq \alpha}) \rightarrow \mathcal{C}$ with the following properties: 04L0

- (a) For every nonzero limit ordinal $\lambda \leq \alpha$, the restriction $F|_{\mathbf{N}_{\bullet}(\mathrm{Ord}_{\leq \lambda})}$ is a colimit diagram: that is, it exhibits $F(\lambda)$ as a colimit of the restriction $F|_{\mathbf{N}_{\bullet}(\mathrm{Ord}_{< \lambda})}$.
- (b) For every ordinal $\beta < \alpha$, the morphism $F(\beta) \rightarrow F(\beta + 1)$ belongs to W .
- (c) The morphism $F(0) \rightarrow F(\alpha)$ coincides with f .

In this case, we will say that F exhibits f as a transfinite composition of morphisms of W .

We say that W is *closed under transfinite composition* if it contains every morphism which is a transfinite composition of morphisms of W .

04L1 **Remark 9.5.1.2.** Let $\mathcal{C}$ be an ordinary category and let W be a collection of morphisms of $\mathcal{C}$. Then a morphism f of $\mathcal{C}$ is a transfinite composition of morphisms belonging to W (in the sense of Definition 1.5.4.10) if and only if the corresponding morphism of the ∞ -category $N_\bullet(\mathcal{C})$ is a transfinite composition of morphisms belonging to W (in the sense of Definition 9.5.1.1).

04L2 **Variant 9.5.1.3.** Let A be a well-ordered set and let α denote its order type. Then there is a unique order-preserving bijection $\text{Ord}_{<\alpha} \simeq A$, which determines an isomorphism of simplicial sets $u : N_\bullet(\text{Ord}_{\leq\alpha}) \simeq N_\bullet(A)^\triangleright$. If $\mathcal{C}$ is an ∞ -category containing a morphism f and a collection of morphisms W , we will say that a diagram $F : N_\bullet(A)^\triangleright \rightarrow \mathcal{C}$ exhibits f as a transfinite composition of morphisms of W if the composition $N_\bullet(\text{Ord}_{\leq\alpha}) \simeq N_\bullet(A)^\triangleright \xrightarrow{F} \mathcal{C}$ exhibits f as a transfinite composition of morphisms of W , in the sense of Definition 9.5.1.1.

006N **Example 9.5.1.4.** Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$. Then every identity morphism of $\mathcal{C}$ is a transfinite composition of morphisms of W (take $\alpha = 0$ in Definition 9.5.1.1). In particular, if W is closed under transfinite composition, then it contains every identity morphism of $\mathcal{C}$.

006P **Example 9.5.1.5.** Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$. Then every morphism of W is a transfinite composition of morphisms of W (take $\alpha = 1$ in Definition 9.5.1.1).

006Q **Example 9.5.1.6.** Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$ which contains a pair of composable morphisms $f : X \rightarrow Y$ and $g : Y \rightarrow Z$. Then any composition of f with g is a transfinite composition of morphisms of W (take $\alpha = 2$ in Definition 1.5.4.10). In particular, if W is closed under transfinite composition, then it is closed under composition.

04L3 **Example 9.5.1.7.** Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be an isomorphism in $\mathcal{C}$. Let F denote the composite map $N_\bullet(\mathbf{Z}_{\geq 0})^\triangleright \twoheadrightarrow (\Delta^0)^\triangleright \simeq \Delta^1 \xrightarrow{f} \mathcal{C}$, which we display informally as a diagram

$$\begin{array}{ccccccc}
 X & \xrightarrow{\text{id}} & X & \xrightarrow{\text{id}} & X & \xrightarrow{\text{id}} & X & \xrightarrow{\text{id}} & \dots \\
 & & \searrow f & & \downarrow f & & \swarrow f & & \\
 & & & & Y & & & &
 \end{array}$$

Since the simplicial set $N_\bullet(\mathbf{Z}_{\geq 0})$ is contractible (Example 3.2.4.2), the functor F is a colimit diagram (Corollary 7.2.3.5), and therefore exhibits f as a transfinite composition of morphisms belonging to the singleton $\{\mathrm{id}_X\}$.

Remark 9.5.1.8. Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$ which is closed under transfinite composition. Combining Examples 9.5.1.4 and 9.5.1.7, we deduce that W contains every isomorphism of $\mathcal{C}$.

Remark 9.5.1.9. Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$ which is closed under transfinite composition. Then W is closed under isomorphism: that is, if f and g are morphisms of $\mathcal{C}$ which are isomorphic (as objects of the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$), then f belongs to W if and only if g belongs to W . This follows by combining Example 9.5.1.6 with Remark 9.5.1.8. In particular, the condition that a morphism f of $\mathcal{C}$ belongs to W depends only on the homotopy class $[f]$.

Example 9.5.1.6 admits a partial converse:

Proposition 9.5.1.10. *Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$. Assume that:*

- (1) *Every identity morphism of $\mathcal{C}$ belongs to W .*
- (2) *The collection W is closed under composition.*
- (3) *The collection W is closed under the formation of colimits in the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$.*

Then W is closed under transfinite composition.

Proof. Let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$ which is a transfinite composition of morphisms of W ; we wish to show that $f \in W$. Choose an ordinal α and a functor $F : N_\bullet(\mathrm{Ord}_{\leq \alpha}) \rightarrow \mathcal{C}$ which exhibits f as a transfinite composition of morphisms of W . For each $\beta \leq \alpha$, the functor F carries the ordered pair $(0 \leq \beta)$ to a morphism $f_\beta : F(0) \rightarrow F(\beta)$. We will complete the proof by showing that each the morphisms f_β belongs to W . The proof proceeds by transfinite induction on β . If $\beta = 0$, then $f_\beta = \mathrm{id}_X$ and the desired result follows from assumption (1). If β is a nonzero limit ordinal, then the desired result follows from assumption (3). Remark 7.4.1.21. It will therefore suffice to treat the case where $\beta = \gamma + 1$ is a successor ordinal. In this case, the desired result follows by applying assumption (2) to the diagram

$$\begin{array}{ccc}
 & F(\gamma) & \\
 f_\gamma \nearrow & & \searrow \\
 X & \xrightarrow{f_\beta} & F(\beta),
 \end{array}$$

since f_γ belongs to W by virtue of our inductive hypothesis. $\square$

04L7 **Remark 9.5.1.11.** In the statement of Proposition 9.5.1.10, it is not necessary to assume that W is closed under the formation of *all* colimits in the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$. It suffices to consider colimits of diagrams indexed by $\mathbf{N}_\bullet(\mathrm{Ord}_{<\beta})$ where β is a limit ordinal; moreover, we can further restrict our attention to colimits which are preserved by the evaluation functors $\mathrm{ev}_0, \mathrm{ev}_1 : \mathrm{Fun}(\Delta^1, \mathcal{C}) \rightarrow \mathcal{C}$.

04L8 **Corollary 9.5.1.12.** *Let $\mathcal{C}$ be an ∞ -category and let W be the collection of all isomorphisms in $\mathcal{C}$. Then W is closed under transfinite composition.*

04L9 **Definition 9.5.1.13.** Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$. The *transfinite closure* of W is the smallest collection of morphisms of $\mathcal{C}$ which contains W and is closed under transfinite composition.

04LA **Example 9.5.1.14.** Let $\mathcal{C}$ be an ∞ -category and let W be the collection of all isomorphisms in $\mathcal{C}$. It follows from Corollary 9.5.1.12 and Example 9.5.1.7 that W is the smallest collection of morphisms of $\mathcal{C}$ which is closed under transfinite composition: that is, it is the transfinite closure of the empty set.

04LB **Warning 9.5.1.15.** Let $\mathcal{C}$ be an ∞ -category, let W be a collection of morphisms of $\mathcal{C}$, and let f be a morphism of $\mathcal{C}$. If f is a transfinite composition of morphisms in W , then it belongs to the transfinite closure of W . Beware that, if we strictly adhere to the terminology of Definition 9.5.1.1, then the converse need not be true. For example, if $W = \emptyset$ and f is an isomorphism, then f belongs to the transfinite closure of W (Example 9.5.1.14). However, f is a transfinite composition of morphisms in W if and only if it is an identity morphism (Example 9.5.1.4).

We can rule out the pathological behavior described in Warning 9.5.1.15 adding a mild additional assumption.

04LC **Proposition 9.5.1.16.** *Let $\mathcal{C}$ be an ∞ -category, let W be a collection of morphisms of $\mathcal{C}$, and let $\overline{W}$ be the collection of all morphisms of $\mathcal{C}$ which are transfinite compositions of morphisms belonging to W . If W contains all identity morphisms, then $\overline{W}$ is closed under transfinite composition (and is therefore the transfinite closure of W).*

Our proof of Proposition 9.5.1.16 will make use of the following:

04LD **Lemma 9.5.1.17.** *Let B be a linearly ordered set and let $A \subseteq B$ be a subset which satisfies the following condition:*

(*) *For every element $b \in B$, the set $\{a \in A : a \leq b\}$ has a largest element b_- , and the set $\{a \in A : b \leq a\}$ has a smallest element b_+ .*

Let $K(A, B) \subseteq N_\bullet(B)$ be the simplicial subset whose n -simplices are given by tuples $(b_0 \leq b_1 \leq b_2 \leq \cdots \leq b_n)$ which satisfy one of the following conditions:

- (1) Each of the elements b_i belongs to A .
- (2) For every element $a \in A$, either $a \leq b_0$ or $a \geq b_n$.

Then the inclusion map $\iota : K(A, B) \hookrightarrow N_\bullet(B)$ is a categorical equivalence of simplicial sets.

Proof. Note that we can identify $K(A, B)$ with the (filtered) colimit of the simplicial subsets $K(A, B')$, where B' ranges over the collection of all subsets of B which are obtained from A by adjoining finitely many elements. Since the collection of categorical equivalences is stable under the formation of filtered colimits (Corollary 4.5.7.2), it will suffice to prove Lemma 9.5.1.17 in the special case where $B \setminus A$ is finite.

Let $A_0 \subseteq A$ be the collection of elements which have the form b_- or b_+ , where b is an element of $B \setminus A$. Note that, if $A' \subseteq A$ is a subset which contains A_0 and we set $B' = A' \cup (B \setminus A)$, then the pair (A', B') also satisfies condition (*). Moreover, we have $K(A', B') = K(A, B) \cap N_\bullet(B')$. It follows that $K(A, B)$ can be written as a filtered colimit of simplicial subsets $K(A', B')$, where A' ranges over finite subsets of A which contain A_0 . Applying Corollary 4.5.7.2 again, we are reduced to proving Lemma 9.5.1.17 under the additional assumption that A is finite. We will also assume that A is nonempty (otherwise, B is empty and therefore is nothing to prove).

If $B = \emptyset$, there is nothing to prove. We may therefore assume without loss of generality that $B = [n] = \{0 < 1 < \cdots < n\}$ for some nonnegative integer n , so that $N_\bullet(B)$ can be identified with the standard n -simplex Δ^n . Note that the simplicial subset $K(A, B) \subseteq \Delta^n$ contains the spine $\text{Spine}[n]$ of Example 1.5.7.7. The inclusion $\text{Spine}[n] \hookrightarrow \Delta^n$ is inner anodyne (Example 1.5.7.7), and therefore a categorical equivalence. It will therefore suffice to show that the inclusion map $\text{Spine}[n] \hookrightarrow K(A, B)$ is also a categorical equivalence. In fact, we will show that it is inner anodyne.

Write $A = \{a_0 < a_1 < \cdots < a_m\}$, where $a_0 = 0$ and $a_m = n$. Then $N_\bullet(A)$ is the image of a nondegenerate m -simplex $\sigma : \Delta^m \rightarrow \Delta^n$, given by $\sigma(i) = a_i$. Let $K' \subseteq \Delta^n$ denote the simplicial subset consisting of simplices which satisfy condition (1): more concretely, K' is the union of the images of nondegenerate simplices

$$\tau_i : \Delta^{a_i - a_{i-1}} \rightarrow \Delta^n \quad k \mapsto k + a_{i-1}.$$

Note that the inverse image $\sigma^{-1}(K')$ identifies with the spine $\text{Spine}[m]$, so that we have a

pushout diagram

$$\begin{array}{ccc} \text{Spine}[m] & \longrightarrow & \Delta^m \\ \downarrow & & \downarrow \sigma \\ K' & \longrightarrow & K(A, B). \end{array}$$

Since the inclusion map $\text{Spine}[m] \hookrightarrow \Delta^m$ is inner anodyne (Example 1.5.7.7), it follows that the inclusion $K' \hookrightarrow K(A, B)$ is also inner anodyne. We are therefore reduced to showing that the inclusion map $\text{Spine}[n] \hookrightarrow K'$ is inner anodyne. This follows from the observation that we also have a pushout diagram

$$\begin{array}{ccc} \coprod_{1 \leq i \leq m} \text{Spine}[a_i - a_{i-1}] & \longrightarrow & \text{Spine}[n] \\ \downarrow & & \downarrow \\ \coprod_{1 \leq i \leq m} \Delta^{a_i - a_{i-1}} & \xrightarrow{\{\tau_i\}} & K', \end{array}$$

where the left vertical map is inner anodyne by virtue of Example 1.5.7.7. $\square$

Proof of Proposition 9.5.1.16. Let $\mathcal{C}$ be an ∞ -category, let W be a collection of morphisms of $\mathcal{C}$, and let $\overline{W}$ be the collection of morphisms which can be written as transfinite compositions of morphisms belonging to W . Suppose we are given a diagram $F : N_\bullet(\text{Ord}_{\leq \alpha}) \rightarrow \mathcal{C}$ which exhibits the underlying map $f : F(0) \rightarrow F(\alpha)$ as a transfinite composition of morphisms of $\overline{W}$. We wish to show that f also belongs to $\overline{W}$.

For each ordinal $\beta < \alpha$, let $u_\beta : F(\beta) \rightarrow F(\beta + 1)$ denote the morphism of $\mathcal{C}$ obtained by evaluating F on the pair $(\beta, \beta + 1)$. By assumption, u_β belongs to $\overline{W}$. We can therefore choose a well-ordered set $(B(\beta), \leq_\beta)$ and a diagram $G_\beta : N_\bullet(B(\beta))^\triangleright \rightarrow \mathcal{C}$ which exhibits u_β as a transfinite composition of morphisms of W , in the sense of Variant 9.5.1.3. Since W contains all isomorphisms in $\mathcal{C}$, we can assume without loss of generality that each $B(\beta)$ is nonempty (see Examples 9.5.1.4 and 9.5.1.5), and therefore contains a smallest element a_β . Let a_α be an auxiliary symbol, set $B(\alpha) = \{a_\alpha\}$, and let B denote the disjoint union $\coprod_{\beta \leq \alpha} B(\beta)$. Given elements $b \in B(\beta)$ and $b' \in B(\beta')$, we write $b \leq b'$ if either $\beta < \beta'$, or $\beta = \beta'$ and $b \leq_\beta b'$. Set $A = \{a_\beta\}_{\beta \leq \alpha} \subseteq B$. The construction $\beta \mapsto a_\beta$ determines an order-preserving bijection $\text{Ord}_{\leq \alpha} \xrightarrow{\sim} A$, so that the diagram F can be identified with a functor from $N_\bullet(A)$ to $\mathcal{C}$. For each $\beta < \alpha$, let us identify G_β with a functor from $N_\bullet(B(\beta) \cup \{a_{\beta+1}\})$ to $\mathcal{C}$. Then the functors F and $\{G_\beta\}_{\beta < \alpha}$ determine a morphism of simplicial sets $H_0 : K(A, B) \rightarrow \mathcal{C}$, where $K(A, B) \subseteq N_\bullet(B)$ is the simplicial subset appearing in the statement of Lemma 9.5.1.17. Since the inclusion map $K(A, B) \hookrightarrow N_\bullet(B)$ is a categorical equivalence of simplicial sets, we can extend H_0 to a diagram $H : N_\bullet(B) \rightarrow \mathcal{C}$.

Note that the linear ordering on B is a well-ordering, with largest element a_α . We claim that H exhibits f as a transfinite composition of morphisms of W , in the sense of Variant 9.5.1.3. It follows immediately from the construction that H carries the pair $(a_0 \leq a_\alpha)$ to the morphism f . Moreover, if an element $b \in B$ has an immediate predecessor $b' \in B$, then there is a (unique) ordinal $\beta < \alpha$ such that both b and b' belong to $B(\beta) \cup \{a_{\beta+1}\}$; our assumption on G_β then guarantees that the morphism $H(b') \rightarrow H(b)$ belongs to W . To complete the proof, it will suffice to show that if $b \neq a_0$ is an element of B which does *not* have an immediate predecessor, then the restriction $H|_{N_\bullet(B_{\leq b})}$ is a colimit diagram in the ∞ -category $\mathcal{C}$. Note that b belongs to $B(\beta)$ for some unique ordinal $0 \leq \beta \leq \alpha$. We consider three cases:

- Suppose that b is not equal to a_β . In this case, the inclusion map $B(\beta)_{<b} \hookrightarrow B_{<b}$ is cofinal (in the sense of Definition 4.7.1.26), and therefore induces a right cofinal morphism of simplicial sets $N_\bullet(B(\beta)_{<b}) \hookrightarrow N_\bullet(B_{<b})$ (Corollary 7.2.3.4). Using Corollary 7.2.2.2, we are reduced to showing that the diagram $H|_{N_\bullet(B(\beta)_{\leq b})}$ is a colimit diagram in $\mathcal{C}$, which follows from our assumption on G_β .
- Suppose that $b = a_\beta$ and that $\beta = \gamma + 1$ is a successor ordinal. In this case, the inclusion map $B_\gamma \hookrightarrow B_{<b}$ is cofinal, and therefore induces a right cofinal morphism of simplicial sets $N_\bullet(B_\gamma) \hookrightarrow N_\bullet(B_{<b})$. The desired result now follows again Corollary 7.2.2.2, since the restriction $H|_{N_\bullet(B_\gamma \cup \{b\})}$ can be identified with G_γ and is therefore a colimit diagram in the ∞ -category $\mathcal{C}$.
- Suppose that $b = a_\beta$, where β is a nonzero limit ordinal. In this case, the inclusion map $A_{<b} \hookrightarrow B_{<b}$ is cofinal and therefore induces a right cofinal morphism of simplicial sets $N_\bullet(A_{<b}) \hookrightarrow N_\bullet(B_{<b})$. Using Corollary 7.2.2.2, we are reduced to showing that the restriction $H|_{N_\bullet(A_{\leq b})}$ is a colimit diagram in $\mathcal{C}$. We conclude by observing that this restriction identifies with $F|_{N_\bullet(\text{Ord}_{\leq \beta})}$.

□

Proposition 9.5.1.18. *Let $\mathcal{C}$ be an ∞ -category, let W be a collection of morphisms of $\mathcal{C}$ which is closed under isomorphism, and let f be a morphism of $\mathcal{C}$ which is a transfinite composition of morphisms of W . If f is not an isomorphism, then it is a transfinite composition of morphisms of W which are not isomorphisms.* 04LE

Proof. Choose a diagram $F : N_\bullet(\text{Ord}_{\leq \alpha}) \rightarrow \mathcal{C}$ which exhibits f as a transfinite composition of morphisms of W . For every pair of ordinals $0 \leq \gamma \leq \beta \leq \alpha$, let $u_{\beta,\gamma} : F(\beta) \rightarrow F(\gamma)$ denote the morphism of $\mathcal{C}$ obtained by evaluating F on the edge $(\gamma \leq \beta)$ of $N_\bullet(\text{Ord}_{\leq \alpha})$. We write $\beta \sim \gamma$ if, for every ordinal λ satisfying $\gamma \leq \lambda \leq \beta$, the morphisms $u_{\beta,\lambda}$ and $u_{\lambda,\gamma}$ are both isomorphisms. It is not difficult to see that this is an equivalence relation on the set

$\text{Ord}_{\leq \alpha}$. For every ordinal $\beta \leq \alpha$, the equivalence class of β contains a smallest element which we will denote by β_- (since $\text{Ord}_{\leq \alpha}$ is well-ordered), and a largest element which we will denote by β_+ (since the collection of isomorphisms is closed under transfinite composition; see Corollary 9.5.1.12).

Choose a subset $A \subseteq \text{Ord}_{\leq \alpha}$ which contains exactly one representative of each $\sim$ -equivalence class. Our assumption that $f = u_{\alpha,0}$ is not an isomorphism guarantees that 0 and α belong to different equivalence classes; we can therefore arrange that both 0 and α are contained in A . We will complete the proof by showing that the diagram $F|_{N_\bullet(A)}$ exhibits f as a transfinite composition of morphisms of W which are not isomorphisms (in the sense of Variant 9.5.1.3).

For any pair of ordinals $\gamma < \beta$ which belong to A , we have inequalities $\gamma \leq \gamma_+ < \beta_- \leq \beta$. Then $u_{\beta,\gamma}$ factors as a composition

$$F(\gamma) \xrightarrow{u_{\gamma_+,\gamma}} F(\gamma_+) \xrightarrow{u_{\beta_-,\gamma_+}} F(\beta_-) \xrightarrow{u_{\beta,\beta_-}} F(\beta),$$

where the maps on the left and right are isomorphisms. In particular, $u_{\beta,\gamma}$ is isomorphic to u_{β_-,γ_+} as an object of the ∞ -category $\text{Fun}(\Delta^1, \mathcal{C})$. If β is an immediate successor of γ in A , then β_- is an immediate successor of γ_+ in $\text{Ord}_{\leq \alpha}$. Our assumption on F then guarantees that u_{β_-,γ_+} is contained in W . Since W is closed under isomorphism, it follows that $u_{\beta,\gamma}$ is also contained in W . Moreover, $u_{\beta,\gamma}$ cannot be an isomorphism (otherwise we would have $\beta \sim \gamma$, contradicting our assumption that A contains exactly one representative of each equivalence class).

For each element $\beta \in A$, set $A_{\leq \beta} = \{\gamma \in A : \gamma \leq \beta\}$ and $A_{< \beta} = \{\gamma \in A : \gamma < \beta\}$. To complete the proof, it will suffice to show that if $\beta \neq 0$ is not the immediate successor of another element of A , then the restriction $F|_{N_\bullet(A_{\leq \beta})}$ is a colimit diagram in the ∞ -category $\mathcal{C}$. Since u_{β,β_-} is an isomorphism, it will suffice to show that $G = F|_{N_\bullet(A_{< \beta} \cup \{\beta_-\})}$ is a colimit diagram (Corollary 7.1.3.15). Our assumption that β has no immediate predecessor in A guarantees that β_- is a limit ordinal and that $A_{< \beta}$ is a cofinal subset of $\text{Ord}_{< \beta_-}$. It follows that the inclusion map $N_\bullet(A_{< \beta}) \hookrightarrow N_\bullet(\text{Ord}_{< \beta_-})$ is right cofinal (Corollary 7.2.3.4). The desired result now follows from Corollary 7.2.2.2, since the restriction $F|_{N_\bullet(\text{Ord}_{\leq \beta_-})}$ is a colimit diagram in $\mathcal{C}$. $\square$

04LF Corollary 9.5.1.19. *Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$ which is closed under isomorphism. Then a morphism f of $\mathcal{C}$ belongs to the transfinite closure of W if and only if f is either an isomorphism or a transfinite composition of morphisms of W .*

Proof. Assume that f belongs to the transfinite closure of W ; we will show that f is either an isomorphism or a transfinite composition of morphisms of W (the converse is clear, since the transfinite closure of W contains all isomorphisms: see Remark 9.5.1.8). Let W^+ be the

union of W with the collection of all identity morphisms of $\mathcal{C}$. Applying Proposition 9.5.1.16, we see that f is a transfinite composition of morphisms of W^+ . If f is not an isomorphism, then Proposition 9.5.1.18 guarantees that f is a transfinite composition of morphisms which belong to W^+ and are not isomorphism, and therefore belong to W . $\square$

9.5.2 Weakly Local Objects

Let $\mathcal{C}$ be a category and let W be a collection of morphisms of $\mathcal{C}$. Recall that an object $C \in \mathcal{C}$ is W -local (in the sense of Definition 6.2.3.1) if, for every morphism $f : X \rightarrow C$ in $\mathcal{C}$ and every morphism $w : X \rightarrow Y$ which belongs to W , there is a unique morphism $g : Y \rightarrow C$ satisfying $g \circ w = f$, as indicated in the diagram

$$\begin{array}{ccc} & Y & \\ w \nearrow & & \searrow g \\ X & \xrightarrow{f} & C. \end{array}$$

It will sometimes be useful to consider the following weaker condition:

Definition 9.5.2.1. Let $\mathcal{C}$ be a category and let $w : X \rightarrow Y$ be a morphism of $\mathcal{C}$. We say that an object $C \in \mathcal{C}$ is *weakly w -local* if, for every morphism $f : X \rightarrow C$ of $\mathcal{C}$, there exists a morphism $g : Y \rightarrow C$ satisfying $g \circ w = f$. If W is a collection of morphisms of $\mathcal{C}$, we say that C is *weakly W -local* if it is weakly w -local for each $w \in W$.

Example 9.5.2.2 (Kan Complexes). Let $\mathcal{C} = \text{Set}_\Delta$ be the category of simplicial sets and let W be the collection of all horn inclusions $\Lambda_i^n \hookrightarrow \Delta^n$, where $n > 0$ and $0 \leq i \leq n$. Then a simplicial set is weakly W -local if and only if it is a Kan complex.

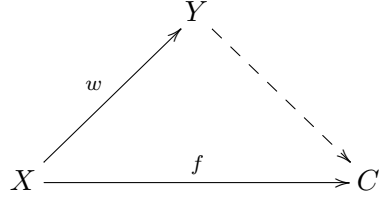

Example 9.5.2.3 (∞ -Categories). Let $\mathcal{C} = \text{Set}_\Delta$ be the category of simplicial sets and let W be the collection of all inner horn inclusions $\Lambda_i^n \hookrightarrow \Delta^n$, where $0 < i < n$. Then a simplicial set is weakly W -local if and only if it is an ∞ -category.

Example 9.5.2.4 (Contractible Kan Complexes). Let $\mathcal{C} = \text{Set}_\Delta$ be the category of simplicial sets and let W be the collection of inclusion maps $\partial\Delta^n \hookrightarrow \Delta^n$. Then a simplicial set is weakly W -local if and only if it is a contractible Kan complex.

Definition 9.5.2.1 has an obvious counterpart in the setting of ∞ -categories:

Definition 9.5.2.5. Let $\mathcal{C}$ be an ∞ -category and let $w : X \rightarrow Y$ be a morphism of $\mathcal{C}$. We say that an object $C \in \mathcal{C}$ is *weakly w -local* if, for every morphism $f : X \rightarrow C$, there exists a

2-simplex with boundary indicated in the diagram

If W is a collection of morphisms of $\mathcal{C}$, we say that an object $C \in \mathcal{C}$ is *weakly W -local* if it is weakly w -local for each $w \in W$.

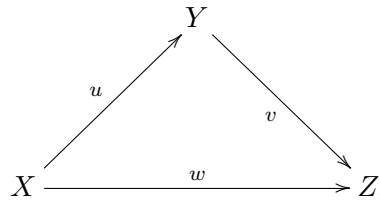

04LN Example 9.5.2.6. Let $\mathcal{C}$ be a category and let W be a collection of morphisms of $\mathcal{C}$. Then an object $C \in \mathcal{C}$ is weakly W -local (in the sense of Definition 9.5.2.1) if and only if it is weakly W -local when regarded as an object of the ∞ -category $N_\bullet(\mathcal{C})$ (in the sense of Definition 9.5.2.5).

04LP Remark 9.5.2.7. Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$. It follows from Proposition 1.4.4.2 that an object $C \in \mathcal{C}$ is weakly W -local if and only if, for every morphism $w : X \rightarrow Y$ which belongs to W , composition with the homotopy class $[w]$ induces a surjection $\mathrm{Hom}_{\mathrm{h}\mathcal{C}}(Y, C) \rightarrow \mathrm{Hom}_{\mathrm{h}\mathcal{C}}(X, C)$. In other words, the object C is weakly W -local (in the sense of Definition 9.5.2.5) if and only if it is weakly $[W]$ -local when regarded as an object of the homotopy category $\mathrm{h}\mathcal{C}$ (in the sense of Definition 9.5.2.1). Here $[W] = \{[w] : w \in W\}$ denotes the collection of all homotopy classes of morphisms which belong to W .

04LQ Example 9.5.2.8. Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$. If an object $C \in \mathcal{C}$ is W -local (in the sense of Definition 6.2.3.1), then it is weakly W -local.

04LR Example 9.5.2.9. Let $\mathcal{C}$ be an ∞ -category and let $w : X \rightarrow Y$ a morphism of $\mathcal{C}$ which admits a left homotopy inverse $r : Y \rightarrow X$. Then every object $C \in \mathcal{C}$ is weakly w -local. In particular, if w is an isomorphism, then every object of $\mathcal{C}$ is weakly w -local.

04LS Remark 9.5.2.10. Let $\mathcal{C}$ be an ∞ -category containing a 2-simplex

If an object $C \in \mathcal{C}$ is weakly u -local and weakly v -local, then it is weakly w -local. Conversely, if C is weakly w -local, then it is weakly u -local.

Remark 9.5.2.11. Let $\mathcal{C}$ be an ∞ -category, let W be a collection of morphisms of $\mathcal{C}$, and 04LT
let $C \in \mathcal{C}$ be an object which factors as a product of some collection of objects $\{C_i\}_{i \in I}$ (see
Definition 7.6.1.3). If each C_i is weakly W -local, then C is weakly W -local. In particular,
any final object of $\mathcal{C}$ is weakly W -local.

Remark 9.5.2.12. Let $\mathcal{C}$ be an ∞ -category, let W be a collection of morphisms of $\mathcal{C}$, and 04LU
let $C \in \mathcal{C}$ be an object. If C is weakly W -local, then any retract of C is also weakly W -local.
Similarly, if C is W -local, then any retract of C is W -local. In particular, the condition that
 C is (weakly) W -local depends only on the isomorphism class of C .

Variant 9.5.2.13. Let $\mathcal{C}$ be an ∞ -category, let $w : X \rightarrow Y$ and $w' : X' \rightarrow Y'$ be morphisms 04LV
of $\mathcal{C}$, and suppose that w' is a retract of w (in the ∞ -category $\text{Fun}(\Delta^1, \mathcal{C})$). If an object
 $C \in \mathcal{C}$ is weakly w -local, then it is also weakly w' -local. Similarly, if C is w -local, then it is
also w' -local. In particular, if we regard the object $C \in \mathcal{C}$ is fixed, then the condition that C
is (weakly) w -local depends only on the isomorphism class of w (as an object of $\text{Fun}(\Delta^1, \mathcal{C})$).

Proposition 9.5.2.14. Let $\mathcal{C}$ be an ∞ -category containing a pushout diagram 04LW

$$\begin{array}{ccc} X & \longrightarrow & X' \\ \downarrow w & & \downarrow w' \\ Y & \longrightarrow & Y' \end{array} \quad (9.13) \quad 04LX$$

If an object $C \in \mathcal{C}$ is weakly w -local, then it is also weakly w' -local.

Proof. We have a commutative diagram of sets

$$\begin{array}{ccccc} \text{Hom}_{\text{h}\mathcal{C}}(Y', C) & \longrightarrow & \text{Hom}_{\text{h}\mathcal{C}}(X', C) \times_{\text{Hom}_{\text{h}\mathcal{C}}(X, C)} \text{Hom}_{\text{h}\mathcal{C}}(Y, C) & \longrightarrow & \text{Hom}_{\text{h}\mathcal{C}}(X', C) \\ & & \downarrow & & \downarrow \\ & & \text{Hom}_{\text{h}\mathcal{C}}(Y, C) & \xrightarrow{\circ[w]} & \text{Hom}_{\text{h}\mathcal{C}}(X, C), \end{array}$$

where the square on the right is a pullback. Our assumption that C is weakly w -local
guarantees that the bottom horizontal map is surjective, so that the upper horizontal map
on the right is also surjective. Since Proposition 9.13 is a pushout square, the horizontal
map on the upper left is also surjective (Warning 7.6.2.3). It follows that the composite map
 $\text{Hom}_{\text{h}\mathcal{C}}(Y', C) \xrightarrow{\circ[w']} \text{Hom}_{\text{h}\mathcal{C}}(X', C)$ is also surjective. $\square$

0696 **Variant 9.5.2.15.** Let $\mathcal{C}$ be an ∞ -category containing a pushout square

04KQ

$$\begin{array}{ccc} X & \longrightarrow & X' \\ \downarrow w & & \downarrow w' \\ Y & \longrightarrow & Y'. \end{array} \quad (9.14)$$

If an object $C \in \mathcal{C}$ is w -local, then it is also w' -local. This follows from Corollary 7.6.2.27, together with the observation that the representable functor $h_C : \mathcal{C}^{\text{op}} \rightarrow \mathcal{S}$ carries pushout diagrams in $\mathcal{C}$ to pullback diagrams in $\mathcal{S}$ (Corollary 7.4.1.19).

04KX **Corollary 9.5.2.16.** Let $\mathcal{C}$ be an ∞ -category and suppose we are given a pushout diagram

04KY

$$\begin{array}{ccc} X & \xrightarrow{w} & Y \\ \downarrow & & \downarrow \\ X' & \xrightarrow{w'} & Y' \end{array} \quad (9.15)$$

in $\mathcal{C}$. If W is a localizing collection of morphisms of $\mathcal{C}$ which contains w , then it also contains w' .

Proof. Let $\mathcal{C}' \subseteq \mathcal{C}$ be the full subcategory spanned by the W -local objects. Since W is localizing, it coincides with the collection of $\mathcal{C}'$ -local equivalences (Proposition 6.2.3.12), and is therefore closed under pushouts by virtue of Variant 9.5.2.15. $\square$

04KS **Remark 9.5.2.17.** Let $\mathcal{C}$ be an ∞ -category which admits pushouts, let $w : X \rightarrow Y$ be a morphism of $\mathcal{C}$, and let $\gamma_{X/Y} : Y \amalg_X Y \rightarrow Y$ be the relative codiagonal of w (see Variant 7.6.2.16). If an object $C \in \mathcal{C}$ is w -local (Definition 6.2.3.1), then it is also $\gamma_{X/Y}$ -local. This follows by applying Remark 6.2.3.6 to the diagram

$$\begin{array}{ccc} & Y \amalg_X Y & \\ w' \nearrow & & \searrow \gamma_{X/Y} \\ Y & \xrightarrow{\text{id}} & Y; \end{array}$$

here w' is a pushout of w (so that C is w' -local by virtue of Variant 9.5.2.15).

Example 9.5.2.8 admits the following partial converse:

Proposition 9.5.2.18. *Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$. Suppose that every morphism $w : X \rightarrow Y$ of W admits a relative codiagonal $\gamma_{X/Y} : Y \amalg_X Y \rightarrow Y$ which also belongs to W (Variant 7.6.2.16). Then an object $C \in \mathcal{C}$ is W -local if and only if it is weakly W -local.* 04LY

Proof. Fix an object $C \in \mathcal{C}$, and let $h_C : \mathcal{C}^{\text{op}} \rightarrow \mathcal{S}$ denote the functor represented by C . We wish to show that, for every morphism $w : X \rightarrow Y$ which belongs to W , the image $h_C(w)$ is a homotopy equivalence of Kan complexes. By virtue of Remark 3.5.1.19, it will suffice to show that $h_C(w)$ is n -connective for every integer $n \geq 0$. The proof proceeds by induction on n . In the case $n = 0$, we wish to show that the composition map $\text{Hom}_{\mathcal{C}}(Y, C) \rightarrow \text{Hom}_{\mathcal{C}}(X, C)$ is surjective on connected components, which follows from our assumption that C is weakly W -local. Let us therefore assume that $n > 0$. Using the criterion of Corollary 3.5.1.29 (together with Exercise 7.6.3.13), we are reduced to proving the $(n - 1)$ -connectivity of the relative diagonal of $h_C(w)$ (formed in the ∞ -category $\mathcal{S}$). Since the functor h_C preserves limits (Proposition 7.4.1.18), we can identify the relative diagonal of $h_C(w)$ with $h_C(\gamma_{X/Y})$, where $\gamma_{X/Y} : Y \amalg_X Y \rightarrow Y$ denotes a relative codiagonal of w . By assumption, we can arrange that $\gamma_{X/Y}$ is also contained in W , so the desired result follows from our inductive hypothesis. $\square$

Exercise 9.5.2.19. Let $\mathcal{C}$ be an ∞ -category and let $w : X \rightarrow Y$ be a morphism of $\mathcal{C}$ which admits a relative codiagonal $\gamma_{X/Y} : Y \amalg_X Y \rightarrow Y$. Show that an object $C \in \mathcal{C}$ is w -local if and only if it is both $\gamma_{X/Y}$ -local and weakly w -local. 04LZ

We have the following ∞ -categorical counterpart of Proposition 1.5.4.12:

Proposition 9.5.2.20. *Let $\mathcal{C}$ be an ∞ -category, let $C \in \mathcal{C}$ be an object, and let W be the collection of morphisms $w : X \rightarrow Y$ in $\mathcal{C}$ such that C is weakly w -local. Then W is closed under transfinite composition (see Definition 9.5.1.1).* 04M0

Proof. Let $U : \mathcal{C}_{/C} \rightarrow \mathcal{C}$ be the projection map and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$ which can be written as a transfinite composition of morphisms of $\mathcal{C}$. Suppose we are given a morphism $X \rightarrow C$ in $\mathcal{C}$, which we identify with an object $\tilde{X} \in \mathcal{C}_{/C}$ satisfying $U(\tilde{X}) = X$. We wish to show that there is a morphism $\tilde{f} : \tilde{X} \rightarrow \tilde{Y}$ of $\mathcal{C}_{/C}$ satisfying $U(\tilde{f}) = f$.

Choose an ordinal α and a functor $F : \mathbf{N}_{\bullet}(\text{Ord}_{\leq \alpha}) \rightarrow \mathcal{C}$ which exhibits f as a transfinite composition of morphisms of W . Let Q be the collection of all ordered pairs $(\beta, \tilde{F}_{\leq \beta})$, where $\beta \leq \alpha$ is an ordinal and $\tilde{F}_{\leq \beta} : \mathbf{N}_{\bullet}(\text{Ord}_{\leq \beta}) \rightarrow \mathcal{C}_{/C}$ is a functor satisfying $\tilde{F}_{\leq \beta}(0) = \tilde{X}$ and $U \circ \tilde{F}_{\leq \beta} = F|_{\mathbf{N}_{\bullet}(\text{Ord}_{\leq \beta})}$. We regard Q as a partially ordered set, where $(\beta, \tilde{F}_{\leq \beta}) \leq (\beta', \tilde{F}'_{\leq \beta'})$ if $\beta \leq \beta'$ and $\tilde{F}_{\leq \beta} = \tilde{F}'_{\leq \beta'}|_{\mathbf{N}_{\bullet}(\text{Ord}_{\leq \beta})}$.

We first claim that Q satisfies the hypotheses of Zorn's lemma. Let $Q_0 \subseteq Q$ be a linearly ordered subset of Q ; we wish to show that Q_0 admits an upper bound. If Q_0 is empty, we can take this upper bound be the pair $(0, \tilde{F}_{\leq 0})$, where $\tilde{F}_{\leq 0}$ is the constant functor taking the

value $\tilde{X}$. Without loss of generality, we may assume that Q_0 does not contain a maximal element (otherwise, there is nothing to prove). Write $Q_0 = \{(\beta_i, \tilde{F}_{\leq \beta_i})\}_{i \in I}$ and let $\beta \leq \alpha$ be the supremum of the set $\{\beta_i\}_{i \in I}$. The functors $\tilde{F}_{\leq \beta_i}$ can then be amalgamated to a single functor $\tilde{F}_{< \beta} : \mathbf{N}_\bullet(\text{Ord}_{< \beta}) \rightarrow \mathcal{C}_{/C}$. To find an upper bound for Q_0 , it will suffice to show that the lifting problem

$$\begin{array}{ccc} \mathbf{N}_\bullet(\text{Ord}_{< \beta}) & \xrightarrow{\tilde{F}_{< \beta}} & \mathcal{C}_{/C} \\ \downarrow & & \downarrow U \\ \mathbf{N}_\bullet(\text{Ord}_{\leq \beta}) & \xrightarrow{F|_{\mathbf{N}_\bullet(\text{Ord}_{\leq \beta})}} & \mathcal{C} \end{array}$$

admits a solution. This follows immediately from our assumption that $F|_{\mathbf{N}_\bullet(\text{Ord}_{\leq \beta})}$ is a colimit diagram in $\mathcal{C}$.

Applying Zorn's lemma, we deduce that Q contains a maximal element $(\beta, \tilde{F}_{\leq \beta})$. To complete the proof, it will suffice to show that $\beta = \alpha$; we can then take $\tilde{f}$ to be obtained by applying the functor $\tilde{F}$ to the edge of $\mathbf{N}_\bullet(\text{Ord}_{\leq \alpha})$ given by the pair $(0, \alpha)$. Assume otherwise, let $F_{\leq \beta}$ denote the restriction $F|_{\mathbf{N}_\bullet(\text{Ord}_{\leq \beta})}$, and let $\mathcal{D}$ denote the coslice ∞ -category $\mathcal{C}_{F_{\leq \beta}/}$. Then $F_{\leq \beta+1}$ and $\tilde{F}_{\leq \beta}$ can be identified with objects $D, D' \in \mathcal{D}$, and the maximality of $(\beta, \tilde{F}_{\leq \beta})$ guarantees that $\text{Hom}_{\mathcal{D}}(D, D') = \emptyset$. Since the inclusion map $\{\beta\} \hookrightarrow \mathbf{N}_\bullet(\text{Ord}_{\leq \beta})$ is right anodyne (Corollary 4.6.7.25), the restriction map $V : \mathcal{D} = \mathcal{C}_{F_{\leq \beta}/} \rightarrow \mathcal{C}_{F(\beta)/}$ is a trivial Kan fibration (Corollary 4.3.6.14). It follows that the mapping space $\text{Hom}_{\mathcal{C}_{F(\beta)/}}(V(D), V(D'))$ is also empty: that is, there is no 2-simplex of $\mathcal{C}$ with boundary indicated in the diagram

$$\begin{array}{ccc} & F(\beta + 1) & \\ & \nearrow & \dashrightarrow \\ F(\beta) & \xrightarrow{\quad} & C. \end{array}$$

This contradicts our assumption that the morphism $F(\beta) \rightarrow F(\beta + 1)$ belongs to W . $\square$

04M1 Variant 9.5.2.21. Let $\mathcal{C}$ be an ∞ -category, let $C \in \mathcal{C}$ be an object, and let W be the collection of morphisms $w : X \rightarrow Y$ in $\mathcal{C}$ such that C is w -local. Then W is closed under transfinite composition.

Proof. Let $\mathcal{C}$ be an ∞ -category, let $C \in \mathcal{C}$ be an object, and let W be the collection of morphisms w of $\mathcal{C}$ such that C is w -local. Then W contains all identity morphisms, is closed under composition (Remark 6.2.3.6), and is closed under the formation of colimits in the ∞ -category $\text{Fun}(\Delta^1, \mathcal{C})$ which are preserved by the evaluation functors $\text{ev}_0, \text{ev}_1 : \text{Fun}(\Delta^1, \mathcal{C}) \rightarrow \mathcal{C}$

(Remark 7.4.1.21). Applying Proposition 9.5.1.10 (and Remark 9.5.1.11), we conclude that W is closed under transfinite composition. $\square$

We now introduce some terminology which is motivated by the preceding discussion.

Definition 9.5.2.22. Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$. 04M2 We will say that W is *weakly saturated* if it satisfies the following conditions:

- (1) The collection W is closed under pushouts: that is, for every pushout diagram

$$\begin{array}{ccc} X & \longrightarrow & X' \\ \downarrow w & & \downarrow w' \\ Y & \longrightarrow & Y' \end{array}$$

in the ∞ -category $\mathcal{C}$, if w belongs to W , then w' also belongs to W .

- (2) The collection W is closed under the formation of retracts (in the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$).

- (3) The collection W is closed under transfinite composition (Definition 9.5.1.1).

Remark 9.5.2.23. Let $\mathcal{C} = N_\bullet(\mathcal{C}_0)$ be the nerve of an ordinary category $\mathcal{C}_0$. Then a 04M3 collection of morphisms of $\mathcal{C}$ is weakly saturated (in the sense of Definition 9.5.2.22) if and only if it is weakly saturated when regarded as a collection of morphisms of $\mathcal{C}_0$ (in the sense of Definition 1.5.4.13).

Example 9.5.2.24. Let $\mathcal{C}$ be an ∞ -category, let $C \in \mathcal{C}$ be an object, and let W be the 04M4 collection of all morphisms $w : X \rightarrow Y$ of $\mathcal{C}$ such that C is weakly w -local. Then W is weakly saturated. This follows from Proposition 9.5.2.14, Variant 9.5.2.13, and Proposition 9.5.2.20.

Variant 9.5.2.25. Let $\mathcal{C}$ be an ∞ -category, let $C \in \mathcal{C}$ be an object, and let W be the 04M5 collection of all morphisms $w : X \rightarrow Y$ of $\mathcal{C}$ such that C is w -local. Then W is weakly saturated. This follows from Variants 9.5.2.15, 9.5.2.13, and 9.5.2.21.

Remark 9.5.2.26. Let $\mathcal{C}$ be an ∞ -category. Any intersection of weakly saturated collections 04M6 of morphisms of $\mathcal{C}$ is also weakly saturated. In particular, for any collection W of morphisms of $\mathcal{C}$, there is a smallest collection $\overline{W}$ which is weakly saturated and contains W . We will refer to $\overline{W}$ as the *weakly saturated collection generated by W* .

9.5.3 The Small Object Argument

04M7 In §3.1.7, we showed that every simplicial set X admits an anodyne morphism $X \hookrightarrow Q$, where Q is a Kan complex (Corollary 3.1.7.2). The proof is easy to describe: if X is not a Kan complex, then there is some horn $\sigma_0 : \Lambda_i^n \rightarrow X$ which cannot be extended to an n -simplex of X . This defect can be remedied by replacing X by the pushout $\Delta^n \amalg_{\Lambda_i^n} X$. The desired Kan complex Q is obtained by a (possibly transfinite) iteration of this procedure. A similar strategy can be used to prove many related results (see for example Exercise 3.1.7.11, Proposition 4.1.3.2, and Proposition 4.2.4.7). Following Quillen ([50]), we will refer to this proof strategy as the *small object argument*. Our goal in this section is to formalize a version of this argument in the ∞ -categorical setting. First, we need a bit of terminology.

04M8 **Definition 9.5.3.1.** Let $\mathcal{C}$ be an ∞ -category, let W be a collection of morphisms of $\mathcal{C}$, and let W' denote the collection of those morphisms $w' : X' \rightarrow Y'$ for which there exists a pushout square

$$\begin{array}{ccc} X & \xrightarrow{\quad} & X' \\ \downarrow w & & \downarrow w' \\ Y & \xrightarrow{\quad} & Y', \end{array}$$

where $w \in W$. We say that a morphism f of $\mathcal{C}$ is a *transfinite pushout of morphisms of W* if it is a transfinite composition of morphisms of W' , in the sense of Definition 9.5.1.1.

04M9 **Remark 9.5.3.2.** Let $\mathcal{C}$ be an ∞ -category, let W be a collection of morphisms of $\mathcal{C}$, and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$ which is a transfinite pushout of morphisms which belong to W . Then:

- If an object $C \in \mathcal{C}$ is weakly W -local, then it is weakly f -local.
- If an object $C \in \mathcal{C}$ is W -local, then it is f -local.

The first assertion follows from Propositions 9.5.2.14 and 9.5.2.20; the second follows from Variant 9.5.2.15 and Variant 9.5.2.21.

We can now formulate the main result of this section:

04MA **Theorem 9.5.3.3** (The Small Object Argument). *Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$. Assume that:*

- *The ∞ -category $\mathcal{C}$ is locally small and admits small colimits.*
- *The collection W is small.*

- For each morphism $w : X \rightarrow Y$ which belongs to W , the object $X \in \mathcal{C}$ is κ -compact for some small cardinal κ (see Definition [?]).

For every object $C \in \mathcal{C}$, there exists a morphism $f : C \rightarrow C'$ where C' is weakly W -local and f is a transfinite pushout of morphisms of W .

Warning 9.5.3.4. If $\mathcal{C}$ is (the nerve of) an ordinary category, then the morphism $f : C \rightarrow C'$ 04MB of Theorem 9.5.3.3 can be chosen to depend functorially on C . Beware that this is generally not possible if $\mathcal{C}$ is an ∞ -category (see Example 9.5.3.5).

Example 9.5.3.5. Fix an integer $n \geq 0$. Let $\mathcal{C} = \mathcal{S}$ be the ∞ -category of spaces and 04MC let W be the collection of morphisms of $\mathcal{C}$ given by the inclusion maps $\{\mathrm{Ex}^\infty(\partial\Delta^m) \hookrightarrow \mathrm{Ex}^\infty(\Delta^m)\}_{0 \leq m \leq n}$. Then an object $X \in \mathcal{C}$ weakly W -local if and only if it is n -connective (see Definition 3.5.1.1). In this case, Theorem 9.5.3.3 asserts that every Kan complex X admits a morphism $f : X \rightarrow Y$, where Y is an n -connective Kan complex which can be obtained from X by attaching cells of dimension $\leq n$. Beware that, if $n > 0$, then Y cannot be chosen to depend functorially on X .

Corollary 9.5.3.6. Let $\mathcal{C}$ be an ∞ -category, let W be a collection of morphisms of $\mathcal{C}$, and 04MD let $\mathcal{C}' \subseteq \mathcal{C}$ be the full subcategory spanned by the W -local objects. Assume that:

- The ∞ -category $\mathcal{C}$ is locally small and admits small colimits.
- The collection W is small.
- For each morphism $w : X \rightarrow Y$ which belongs to W , the objects X and Y are κ -compact for some small infinite cardinal κ .

Then $\mathcal{C}'$ is a reflective localization of $\mathcal{C}$.

Proof. For each morphism $w : X \rightarrow Y$ of $\mathcal{C}$, choose a morphism $\delta_w : Y \amalg_X Y \rightarrow Y$ which is a relative codiagonal of w (see Variant 7.6.2.16). Note that, if X and Y are κ -compact for some infinite cardinal κ , then the pushout $Y \amalg_X Y$ is also κ -compact (Proposition [?]). Let W' be the smallest collection of morphisms of $\mathcal{C}$ which contains W and is closed under the construction $w \mapsto \gamma_w$. By virtue of Remark 9.5.2.17, an object of $\mathcal{C}$ is W -local if and only if it is W' -local. We may therefore replace W by W' and thereby reduce to proving Corollary 9.5.3.6 in the special case where W is closed under the formation of relative codiagonals.

Fix an object $C \in \mathcal{C}$. Using Theorem 9.5.3.3, we see that there exists a morphism $f : C \rightarrow C'$, where C' is weakly W -local and f is a transfinite pushout of morphisms which belong to W . Using Proposition 9.5.2.18, we see that C' belongs to the subcategory $\mathcal{C}' \subseteq \mathcal{C}$. To complete the proof, it will suffice to show that f exhibits C' as a $\mathcal{C}'$ -reflection of C : that is, every object of $\mathcal{C}'$ is f -local. This follows from Remark 9.5.3.2. $\square$

Our proof of Theorem 9.5.3.3 will require some preliminaries.

04ME Lemma 9.5.3.7. *Let $\mathcal{C}$ be an ∞ -category which admits small colimits, let $\{w_s : X_s \rightarrow Y_s\}_{s \in S}$ be a small collection of morphisms of $\mathcal{C}$ indexed by a set S , let $\{e_s : X_s \rightarrow C\}_{s \in S}$ be another collection of morphisms of $\mathcal{C}$, and let D be a colimit of the diagram*

$$(S \times \Delta^1) \coprod_{S \times \{0\}} S^{\triangleright} \xrightarrow{(\{w_s\}, \{e_s\})} \mathcal{C}.$$

Then the tautological map $u : C \rightarrow D$ is a transfinite pushout of morphisms belonging to $\{w_s\}_{s \in S}$.

Proof. Using the well-ordering theorem (Theorem 4.7.1.34), we can choose an ordinal α and a bijection $\ell : S \rightarrow \text{Ord}_{<\alpha}$. Let Q denote the disjoint union $(S \times [1]) \coprod \text{Ord}_{\leq \alpha}$. For elements $q, q' \in Q$, we write $q \leq q'$ if (exactly) one of the following conditions holds:

- There exist an element $s \in S$ such that $q = (s, i)$ and $q' = (s, i')$, where $i \leq i'$.
- We have $q = \beta$ and $q' = \beta'$ for ordinals $\beta, \beta' \in \text{Ord}_{\leq \alpha}$ satisfying $\beta \leq \beta'$ (for the usual ordering of $\text{Ord}_{\leq \alpha}$).
- We have $q = (s, 0)$ for some $s \in S$ and $q' = \beta$ for some $\beta \in \text{Ord}_{\leq \alpha}$.
- We have $q = (s, 1)$ and $q' = \beta$ for some $\beta \in \text{Ord}_{\leq \alpha}$ satisfying $\ell(s) < \beta$.

Let $Q_0 = (S \times [1]) \coprod \{0\}$, which we regard as a partially ordered subset of Q . By construction, the nerve $N_{\bullet}(Q_0)$ can be identified with the pushout $(S \times \Delta^1) \coprod_{S \times \{0\}} S^{\triangleright}$. Consequently, the collections $\{e_s\}_{s \in S}$ and $\{w_s\}_{s \in S}$ determine a diagram $F_0 : N_{\bullet}(Q_{\leq 0}) \rightarrow \mathcal{C}$. Since $\mathcal{C}$ admits small colimits, the diagram F_0 admits a left Kan extension $F : N_{\bullet}(Q) \rightarrow \mathcal{C}$ (Proposition 7.6.6.18). Then $D = F(\alpha)$ is a colimit of the diagram F_0 , and we can identify u with the morphism obtained by evaluating the functor F on the edge of $N_{\bullet}(Q)$ given by the pair $(0 \leq \alpha)$. We will show that the restriction $F|_{N_{\bullet}(\text{Ord}_{\leq \alpha})}$ exhibits u as a transfinite pushout of morphisms belonging to $\{w_s\}_{s \in S}$.

We first claim that if $\beta \leq \alpha$ is a nonzero limit ordinal, then the restriction $F|_{N_{\bullet}(\text{Ord}_{\leq \beta})}$ is a colimit diagram in $\mathcal{C}$. Set $Q_{\leq \beta} = \{q \in Q : q \leq \beta\}$ and $Q_{<\beta} = \{q \in Q : q < \beta\}$. Since the functor F is left Kan extended from $N_{\bullet}(Q_0)$, it is also left Kan extended from larger ∞ -category $N_{\bullet}((S \times [1]) \coprod \text{Ord}_{<\beta})$ (see Corollary 7.3.8.13). It follows that $F|_{N_{\bullet}(Q_{\leq \beta})}$ is a colimit diagram in $\mathcal{C}$. It will therefore suffice to show that $N_{\bullet}(\iota)$ is right cofinal, where ι denotes the inclusion map $\text{Ord}_{<\beta} \hookrightarrow Q_{<\beta}$ (Corollary 7.2.2.2). This is a special case of Corollary 7.2.3.7, since ι admits a left adjoint (given on $S \times [1]$ by the construction $(s, 0) \mapsto 0$ and $(s, 1) \mapsto \ell(s) + 1$).

Now suppose that $\beta = \gamma + 1$ is a successor ordinal. Let $s \in S$ be the unique element satisfying $\ell(s) = \gamma$. We will complete the proof by showing that the morphism $F(\gamma) \rightarrow F(\beta)$

in $\mathcal{C}$ can be realized as a pushout of w_s . More precisely, we will show that the functor F carries the diagram

$$\begin{array}{ccc} (s, 0) & \longrightarrow & (s, 1) \\ \downarrow & & \downarrow \\ \gamma & \longrightarrow & \beta \end{array}$$

in $N_\bullet(Q)$ to a pushout diagram in the ∞ -category $\mathcal{C}$. Arguing as above, we see that the restriction $F|_{Q_{\leq \beta}}$ is a colimit diagram. Using Corollary 7.2.2.2 again, we are reduced to showing that $N_\bullet(\iota)$ is right cofinal, where ι denotes the inclusion of partially ordered sets $\{(s, 1) > (s, 0) < \beta\} \hookrightarrow Q_{< \beta}$. This again follows from Corollary 7.2.3.7, since ι admits a left adjoint given by the construction

$$(q \in Q_{< \beta}) \mapsto \begin{cases} q & \text{if } q = (s, 0) \text{ or } q = (s, 1) \\ \beta & \text{otherwise.} \end{cases}$$

□

Lemma 9.5.3.8. *Let $\mathcal{C}$ be a locally small ∞ -category which admits small colimits, and let W be a small collection of morphisms of $\mathcal{C}$. For every object $C \in \mathcal{C}$, there exists a morphism $u : C \rightarrow D$ which is a transfinite pushout of morphisms of W with the following property: for every morphism $w : X \rightarrow Y$ which belongs to W and every morphism $e : X \rightarrow C$, there exists a commutative diagram* 04MF

$$\begin{array}{ccc} X & \xrightarrow{w} & Y \\ \downarrow e & & \downarrow \\ C & \xrightarrow{u} & D \end{array}$$

in the ∞ -category $\mathcal{C}$.

Proof. For each morphism $w : X \rightarrow Y$ belonging to W , let $\{f_s : X \rightarrow C\}_{s \in S_w}$ be a set of representatives for the homotopy classes of morphisms from X to C . Since $\mathcal{C}$ is locally small, the collection S_w is small. Our assumption that W is small then guarantees that the disjoint union $S = \coprod_{w \in W} S_w$ is small. The desired result now follows by applying Lemma 9.5.3.7 to the collection of morphisms $\{f_s\}_{s \in S}$. □

Lemma 9.5.3.9. *Let $\mathcal{C}$ be an ∞ -category which admits small filtered colimits. Let U be a collection of morphisms with the following property: for every object $D \in \mathcal{C}$, there exists a morphism $u : D \rightarrow E$ which belongs to U . Then, for every object $C \in \mathcal{C}$ and every (small) ordinal α , there exists a diagram $F : N_\bullet(\text{Ord}_{\leq \alpha}) \rightarrow \mathcal{C}$ satisfying the following conditions:* 04MG

- (a) For every nonzero limit ordinal $\lambda \leq \alpha$, the restriction $F|_{N_\bullet(\text{Ord}_{\leq \lambda})}$ is a colimit diagram.
- (b) For every ordinal $\gamma < \alpha$, the morphism $F(\gamma) \rightarrow F(\gamma + 1)$ belongs to U .
- (c) The object $F(0)$ coincides with C .

Proof. Let Q denote the collection of all diagrams $F_\beta : N_\bullet(\text{Ord}_{\leq \beta}) \rightarrow \mathcal{C}$ satisfying conditions (a), (b), and (c), where β is an ordinal $\leq \alpha$. We regard Q as a partially ordered set, where $F_\beta \leq F_{\beta'}$ if $\beta \leq \beta'$ and $F_\beta = F_{\beta'}|_{N_\bullet(\text{Ord}_{\leq \beta})}$. Note that Q is nonempty: it has a least element given by the diagram $N_\bullet(\text{Ord}_{\leq 0}) \simeq \{C\} \hookrightarrow \mathcal{C}$ taking the value C . We claim that Q satisfies the hypothesis of Zorn's lemma: that is, every linearly ordered set $Q' \subset Q$ admits an upper bound. Without loss of generality, we may assume that Q' is nonempty and has no largest element. In this case, the elements of Q' can be amalgamated to a diagram $F_{<\lambda} : N_\bullet(\text{Ord}_{<\lambda}) \rightarrow \mathcal{C}$, where $\lambda \leq \alpha$ is a nonzero limit ordinal. Our assumption on $\mathcal{C}$ then guarantees that $F_{<\lambda}$ can be extended to a colimit diagram

$$F_\lambda : N_\bullet(\text{Ord}_{\leq \lambda}) \simeq N_\bullet(\text{Ord}_{<\lambda})^\triangleright \rightarrow \mathcal{C}.$$

By construction, this diagram satisfies conditions (a), (b), and (c), and is therefore an upper bound for Q' .

Applying Zorn's lemma, we deduce that Q has a maximal element $F_\beta : N_\bullet(\text{Ord}_{\leq \beta}) \rightarrow \mathcal{C}$. We will complete the proof by showing that $\beta < \alpha$. Assume otherwise, and set $X = F_\beta(\beta)$. By assumption, we can choose a morphism $u : X \rightarrow Y$ which belongs to U . Let us identify u with an object $\tilde{Y}$ of the coslice ∞ -category $\mathcal{C}_{X/}$. Since the inclusion map $\{\beta + 1\} \hookrightarrow N_\bullet(\text{Ord}_{\leq \beta+1})$ is right anodyne (Example 4.3.7.11), the restriction map $\mathcal{C}_{F_\beta/} \rightarrow \mathcal{C}_{X/}$ is a trivial Kan fibration (Corollary 4.3.6.14). We can therefore lift $\tilde{Y}$ to an object of the ∞ -category $\mathcal{C}_{F_\beta/}$, which we can identify with an extension of F_β to a diagram $F_{\beta+1} : N_\bullet(\text{Ord}_{\leq \beta+1}) \rightarrow \mathcal{C}$. By construction, this diagram carries the pair $(\beta, \beta + 1)$ to the morphism u of $\mathcal{C}$. It follows that $F_{\beta+1}$ is also an element of Q , contradicting the maximality of F_β . $\square$

Proof of Theorem 9.5.3.3. Let $\mathcal{C}$ be a locally small ∞ -category which admits small colimits, let W be a small collection of morphisms of $\mathcal{C}$, and let κ be a small regular cardinal having the property that for each morphism $w : X \rightarrow Y$ which belongs to W , the object X is κ -compact. Fix an object $C \in \mathcal{C}$; we wish to show that there exists a morphism $f : C \rightarrow C'$ where C' is weakly W -local and f is a transfinite pushout of morphisms belonging to W . Without loss of generality, we may assume that C itself is not weakly W -local (otherwise, we can take $f = \text{id}_C$).

Let W' be the collection of all morphisms of $\mathcal{C}$ which are pushouts of morphisms of W , and let $\overline{W}$ denote the transfinite closure of W' (Definition 9.5.1.13). Let $U \subseteq \overline{W}$ denote the subcollection consisting of those morphisms u which satisfy the requirement of Lemma 9.5.3.8. Using Lemma 9.5.3.9 we deduce that there exists a diagram $F : N_\bullet(\text{Ord}_{\leq \kappa}) \rightarrow \mathcal{C}$

where $F(0) = C$ and F exhibits the induced map $F(0) \xrightarrow{f} F(\kappa)$ as a transfinite composition of morphisms of U .

We first claim that the object $C' = F(\kappa)$ is weakly W -local. Let $w : X \rightarrow Y$ be a morphism which belongs to W . We wish to show that every morphism $[\bar{e}] : X \rightarrow F(\kappa)$ in the homotopy category $\mathbf{h}\mathcal{C}$ factors through the homotopy class $[w]$. Since F is a colimit diagram and the object X is κ -compact, the morphism $[\bar{e}]$ factors as a composition $X \xrightarrow{[e]} F(\alpha) \rightarrow F(\kappa)$ for some ordinal $\alpha < \kappa$ and some morphism $e : X \rightarrow F(\alpha)$ in the ∞ -category $\mathcal{C}$. Since the transition map $F(\alpha) \rightarrow F(\alpha + 1)$ belongs to U , we can choose a commutative diagram

$$\begin{array}{ccc} X & \xrightarrow{w} & Y \\ \downarrow e & & \downarrow e' \\ F(\alpha) & \longrightarrow & F(\alpha + 1). \end{array}$$

It follows that $[\bar{e}]$ factors as a composition $X \xrightarrow{[w]} Y \xrightarrow{[e']} F(\alpha + 1) \rightarrow F(\kappa)$.

To complete the proof, it will suffice to show that f is a transfinite composition of morphisms belonging to W' . By construction, f is a transfinite pushout of morphisms of $U \subseteq \overline{W}$, and therefore belongs to $\overline{W}$. This follows from Corollary 9.5.1.19, since f is not an isomorphism (otherwise, the object C would also be weakly W -local, contrary to our initial assumption). $\square$

9.5.4 Lifting Problems in ∞ -Categories

Let $\mathcal{C}$ be a category. Recall that a *lifting problem in $\mathcal{C}$* is a commutative diagram

04MH

$$\begin{array}{ccc} A & \xrightarrow{u_0} & X \\ \downarrow f & & \downarrow g \\ B & \xrightarrow{\bar{u}} & Y \end{array}$$

04MJ

(9.16)

In this case, a *solution* to the lifting problem (9.16) is a morphism $u : B \rightarrow X$ satisfying $u \circ f = u_0$ and $g \circ u = \bar{u}$ (see Definition 1.5.4.1). This definition has an obvious ∞ -categorical counterpart:

Definition 9.5.4.1 (Lifting Problems in ∞ -Categories). Let $\mathcal{C}$ be an ∞ -category. A *lifting problem in $\mathcal{C}$* is a diagram $\sigma : \Delta^1 \times \Delta^1 \rightarrow \mathcal{C}$. In this case, a *solution* to the lifting problem σ is a 3-simplex $\bar{\sigma} : \Delta^3 \rightarrow \mathcal{C}$ for which the composition

$$\Delta^1 \times \Delta^1 \xrightarrow{\alpha} \Delta^3 \xrightarrow{\bar{\sigma}} \mathcal{C}$$

04MK

coincides with σ , where α denotes the map of simplicial sets given on vertices by $\alpha(i, j) = 2i + j$.

04ML **Remark 9.5.4.2.** Let us informally display the standard simplex Δ^3 as a diagram

04MM

The morphism $\alpha : \Delta^1 \times \Delta^1 \rightarrow \Delta^3$ appearing in Definition 9.5.4.1 is a monomorphism of simplicial sets, whose image is the simplicial subset $Q \subseteq \Delta^3$ consisting of those simplices which do not contain the “inner” edge $N_\bullet(\{1 < 2\})$ which is indicated by the dotted arrow in the diagram (9.17). Stated more informally, Q is the subset of Δ^3 which is “visible from the top” in the diagram (9.17); in particular, Q contains the inner faces $N_\bullet(\{0 < 1 < 3\})$ and $N_\bullet(\{0 < 2 < 3\})$, but not the outer faces $N_\bullet(\{0 < 1 < 2\})$ and $N_\bullet(\{1 < 2 < 3\})$.

04MN **Notation 9.5.4.3.** Let $\mathcal{C}$ be an ∞ -category. We will often denote a lifting problem σ in $\mathcal{C}$ by a diagram

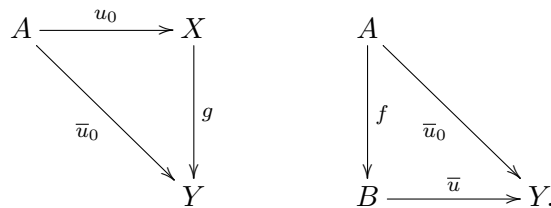

04MP

Here the dotted arrow in the diagram does not indicate part of the data supplied by lifting problem σ ; instead, it indicates part of the data of a hypothetical solution.

Stated more concretely, the lifting problem σ is given by the following data:

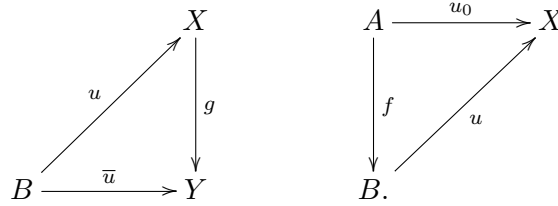

- Four objects of $\mathcal{C}$, which are indicated by A , B , X , and Y in the diagram (9.18).
- Five morphisms of $\mathcal{C}$, which we will denote by $f : A \rightarrow B$, $g : X \rightarrow Y$, $u_0 : A \rightarrow X$, $\bar{u} : B \rightarrow Y$, and $\bar{u}_0 : A \rightarrow Y$. Here the first four of these morphisms are indicated as outer edges of the diagram (9.18), while the fifth is left implicit.
- A pair of 2-simplices τ_1 and τ_2 of $\mathcal{C}$, whose boundaries are indicated in the diagrams

In other words, τ_1 and τ_2 exhibit the morphism $\bar{u}_0$ as a composition $\bar{u} \circ f$ and a composition $g \circ u_0$, respectively.

A solution to the lifting problem σ is given by the following additional data:

- A morphism $u : B \rightarrow X$ (indicated by the dotted arrow in the diagram (9.18)).
- A pair of 2-simplices τ_0 and τ_3 of $\mathcal{C}$, whose boundaries are indicated in the diagrams

In other words, τ_0 exhibits $\bar{u}$ as a composition $g \circ u$, and τ_3 exhibits u_0 as a composition $u \circ f$.

- A 3-simplex of $\mathcal{C}$ having boundary $(\tau_0, \tau_1, \tau_2, \tau_3)$.

Example 9.5.4.4. Let $\mathcal{C}_0$ be a category and let $\mathcal{C} = \mathbf{N}_\bullet(\mathcal{C}_0)$ denote its nerve. Then lifting 04MQ problems σ in the ∞ -category $\mathcal{C}$ (in the sense of Definition 9.5.4.1) can be identified with lifting problems σ_0 in the ordinary category $\mathcal{C}_0$ (in the sense of Definition 1.5.4.1). In this case, we can also identify solutions to σ with solutions to σ_0 .

Warning 9.5.4.5. Let $\mathcal{C}$ be an ∞ -category. Every lifting problem 04MR

$$\begin{array}{ccc} A & \xrightarrow{u_0} & X \\ \downarrow f & \nearrow \text{dotted} & \downarrow g \\ B & \xrightarrow{\bar{u}} & Y \end{array} \quad (9.19)$$

in $\mathcal{C}$ determines a lifting problem in the homotopy category $\mathbf{h}\mathcal{C}$, given by the diagram

$$\begin{array}{ccc} A & \xrightarrow{[u_0]} & X \\ \downarrow [f] & \nearrow \text{dotted} & \downarrow [g] \\ B & \xrightarrow{[\bar{u}]} & Y. \end{array} \quad (9.20)$$

Moreover, every solution to the lifting problem (9.19) determines a solution to the lifting problem (9.20). Beware that the converse is false: it is possible for the lifting problem (9.20) to admit a solution when the lifting problem (9.19) does not (Exercise 9.5.4.6).

04MU **Exercise 9.5.4.6.** Let $g : X \rightarrow S$ be Kan fibration between Kan complexes, where S is connected and X is contractible. Choose a vertex $s \in S$ and let X_s denote the fiber $\{s\} \times_S X$, so that we have a commutative diagram of Kan complexes

04MV

$$\begin{array}{ccc} X_s & \longrightarrow & X \\ \downarrow & & \downarrow f \\ \{s\} & \longrightarrow & S \end{array} \quad (9.21)$$

Show that:

- In the ∞ -category of spaces $\mathcal{S}$, the lifting problem determined by (9.21) admits a solution only if S is contractible.
- In the homotopy category $\mathbf{h}\mathcal{S}$, the lifting problem determined by (9.21) always has a solution.

04MW **Remark 9.5.4.7.** Let $\mathcal{C}$ be an ∞ -category. Fix a morphism $\bar{u}_0 : A \rightarrow Y$ of $\mathcal{C}$, and let $\mathcal{C}_{A//Y}$ denote the ∞ -category of Remark 4.6.6.2. The datum of an extension of $\bar{u}_0$ to a lifting problem σ :

04MX

$$\begin{array}{ccc} A & \longrightarrow & X \\ \downarrow & \nearrow \text{dashed} & \downarrow \\ B & \longrightarrow & Y \end{array} \quad (9.22)$$

can be identified with a pair of objects $\tilde{B}, \tilde{X} \in \mathcal{C}_{A//Y}$. In this case, a solution to the lifting problem (9.22) is a morphism from $\tilde{B}$ to $\tilde{X}$ in the ∞ -category $\mathcal{C}_{A//Y}$.

04MY **Definition 9.5.4.8.** Let $\mathcal{C}$ be an ∞ -category, and let $f : A \rightarrow B$ and $g : X \rightarrow Y$ be morphisms of $\mathcal{C}$. We will say that f is *weakly left orthogonal* to g if every lifting problem

$$\begin{array}{ccc} A & \longrightarrow & X \\ \downarrow f & \nearrow \text{dashed} & \downarrow g \\ B & \longrightarrow & Y \end{array}$$

in the ∞ -category $\mathcal{C}$ admits a solution. In this case, we will also say that g is *weakly right orthogonal* to f .

Example 9.5.4.9. In the situation of Definition 9.5.4.8, suppose that $\mathcal{C}$ is the nerve of a category $\mathcal{C}_0$. Then f is weakly left orthogonal to g (in the sense of Definition 9.5.4.8) if and only if it is weakly left orthogonal to g when regarded as a morphism of the category $\mathcal{C}_0$ (in the sense of Definition 1.5.4.3). 04MZ

Warning 9.5.4.10. Let $\mathcal{C}$ be an ∞ -category containing a pair of morphisms $f : A \rightarrow B$ and $g : X \rightarrow Y$. If f is weakly left orthogonal to g in the ∞ -category $\mathcal{C}$, then the homotopy class $[f]$ is weakly left orthogonal to $[g]$ in the homotopy category $\mathrm{h}\mathcal{C}$ (see Exercise 1.5.2.10). Beware that the converse is false in general (see Warning 9.5.4.5 and Exercise 9.5.4.6). 04N0

Variant 9.5.4.11. Let $\mathcal{C}$ be an ∞ -category and let S and T be collections of morphisms of $\mathcal{C}$. We say that S is *weakly left orthogonal to T* if every morphism $f \in S$ is weakly left orthogonal to every morphism $g \in T$. In this case, we also say that T is *weakly right orthogonal to S* . In the special case where $S = \{f\}$ is a singleton, we abbreviate this condition by saying that f is *weakly left orthogonal to T* , or T is *weakly right orthogonal to f* . In the special case $T = \{g\}$ is a singleton, we abbreviate this condition by saying that g is *weakly right orthogonal to S* , or S is *weakly left orthogonal to g* . 04N1

Remark 9.5.4.12. Let $\mathcal{C}$ be an ∞ -category containing a morphism $g : X \rightarrow Y$, which we identify with an object $\tilde{X}$ of the slice ∞ -category $\mathcal{C}_{/Y}$. Let S be a collection of morphisms of $\mathcal{C}$, and let $\tilde{S}$ denote its inverse image in $\mathcal{C}_{/Y}$. The following conditions are equivalent: 04N2

- The morphism g is weakly right orthogonal to S (in the sense of Variant 9.5.4.11).
- The object $\tilde{X}$ is weakly $\tilde{S}$ -local (in the sense of Definition 9.5.2.5).

Example 9.5.4.13. Let $\mathcal{C}$ be an ∞ -category containing a morphism $g : X \rightarrow Y$. Then every isomorphism f of $\mathcal{C}$ is weakly left orthogonal to g . This follows from the criterion of Remark 9.5.4.12, since every lift of f to the ∞ -category $\mathcal{C}_{/Y}$ is also an isomorphism (Proposition 4.4.2.11). 04N3

We now record a few consequences of Remark 9.5.4.12.

Proposition 9.5.4.14. Let $\mathcal{C}$ be an ∞ -category and let $g : X \rightarrow Y$ be a morphism of $\mathcal{C}$. If another morphism $f : A \rightarrow B$ is weakly left orthogonal to g , then any retract of f (in the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$) is also weakly left orthogonal to g . 04N4

Proof. Let $f' : A' \rightarrow B'$ be a retract of f (in the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$); we will show that f' is weakly left orthogonal to g . Let $\pi : \mathcal{C}_{/Y} \rightarrow \mathcal{C}$ be the projection map, and let us identify g with an object $\tilde{X} \in \mathcal{C}_{/Y}$ satisfying $\pi(\tilde{X}) = X$. By virtue of Remark 9.5.4.12, it will suffice to show that for any morphism $\tilde{f}'$ of $\mathcal{C}_{/Y}$ satisfying $\pi(\tilde{f}') = f'$, the object $\tilde{X}$ is weakly $\tilde{f}'$ -local. It follows from Corollary 4.2.5.2 that π induces a right fibration $\mathrm{Fun}(\Delta^1, \mathcal{C}_{/Y}) \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C})$. Applying Remark 8.5.1.23, we deduce that $\tilde{f}'$ is a retract of a morphism $\tilde{f}$ of $\mathcal{C}_{/Y}$ satisfying

$U(\tilde{f}) = f$. By virtue of Variant 9.5.2.13, it will suffice to show that the object $\tilde{X}$ is weakly $\tilde{f}$ -local, which follows from our assumption that f is weakly left orthogonal to g (Remark 9.5.4.12). $\square$

04N5 **Proposition 9.5.4.15.** *Let $\mathcal{C}$ be an ∞ -category containing a pushout diagram*

$$\begin{array}{ccc} A & \longrightarrow & A' \\ \downarrow f & & \downarrow f' \\ B & \longrightarrow & B'. \end{array} \quad (9.23)$$

If f is weakly left orthogonal to a morphism $g : X \rightarrow Y$ of $\mathcal{C}$, then f' is also weakly left orthogonal to g .

Proof. Let $\pi : \mathcal{C}_{/Y} \rightarrow \mathcal{C}$ be the projection map, and let us identify g with an object $\tilde{X} \in \mathcal{C}_{/Y}$ satisfying $\pi(\tilde{X}) = X$. By virtue of Remark 9.5.4.12, it will suffice to show that for any morphism $\tilde{f}'$ of $\mathcal{C}_{/Y}$ satisfying $\pi(\tilde{f}') = f'$, the object $\tilde{X}$ is weakly $\tilde{f}'$ -local. Since π is a right fibration, we can lift (9.23) to a diagram

$$\begin{array}{ccc} \tilde{A} & \longrightarrow & \tilde{A}' \\ \downarrow \tilde{f} & & \downarrow \tilde{f}' \\ \tilde{B} & \longrightarrow & \tilde{B}' \end{array}$$

in the ∞ -category $\mathcal{C}_{/Y}$, which is also a pushout square (Proposition 7.1.4.21). By virtue of Proposition 9.5.2.14, it will suffice to show that $\tilde{X}$ is weakly $\tilde{f}$ -local, which follows from our assumption that f is weakly left orthogonal to g (Remark 9.5.4.12). $\square$

04N7 **Proposition 9.5.4.16.** *Let $\mathcal{C}$ be an ∞ -category containing a morphism $g : X \rightarrow Y$, and let S be the collection of all morphisms of $\mathcal{C}$ which are weakly left orthogonal to g . Then S is closed under transfinite composition (see Definition 9.5.1.1).*

Proof. Let $f : A \rightarrow B$ be a transfinite composition of morphisms of S ; we wish to show that f is weakly left orthogonal to g . Let $\pi : \mathcal{C}_{/Y} \rightarrow \mathcal{C}$ be the projection map, and let us identify g with an object $\tilde{X} \in \mathcal{C}_{/Y}$ satisfying $\pi(\tilde{X}) = X$. By virtue of Remark 9.5.4.12, it will suffice to show that for every morphism $\tilde{f} : \tilde{A} \rightarrow \tilde{B}$ of $\mathcal{C}_{/Y}$ satisfying $\pi(\tilde{f}) = f$, the object $\tilde{X}$ is weakly $\tilde{f}$ -local.

Choose an ordinal α and a diagram $F : \mathbf{N}_{\bullet}(\text{Ord}_{\leq \alpha}) \rightarrow \mathcal{C}$ which exhibits f as a transfinite composition of morphisms of S (see Definition 9.5.1.1). We will assume that $\alpha > 0$ (otherwise,

f is an identity morphism and the desired result follows from Example 9.5.4.13). In this case, Lemma 4.3.7.8 guarantees that the inclusion map $N_\bullet(\{0 < \alpha\}) \hookrightarrow N_\bullet(\text{Ord}_{\leq \alpha})$ is right anodyne. Since π is a right fibration (Proposition 4.3.6.1), we can lift F to a diagram $\tilde{F} : N_\bullet(\text{Ord}_{\leq \alpha}) \rightarrow \mathcal{C}$ for which the associated morphism $\tilde{F}(0) \rightarrow \tilde{F}(\alpha)$ coincides with $\tilde{f}$. For every nonzero limit ordinal $\lambda \leq \alpha$, Proposition 7.1.4.21 guarantees that the restriction $\tilde{F}|_{N_\bullet(\text{Ord}_{\leq \lambda})}$ is a colimit diagram in the ∞ -category $\mathcal{C}_Y$. Using Remark 9.5.4.12, we see that $\tilde{F}$ exhibits $\tilde{f}$ as a transfinite composition of morphisms of $\mathcal{C}_Y$ with respect to which $\tilde{X}$ is weakly local. Applying Proposition 9.5.2.20, we conclude that $\tilde{X}$ is weakly $\tilde{f}$ -local, as desired. $\square$

Corollary 9.5.4.17. *Let $\mathcal{C}$ be an ∞ -category, let T be a collection of morphisms of $\mathcal{C}$, and 04N8
let S be the collection of all morphisms of $\mathcal{C}$ which are weakly left orthogonal to T . Then S is weakly saturated.*

Proof. Combine Propositions 9.5.4.14, 9.5.4.15, and 9.5.4.16 with Remark 9.5.2.26. $\square$

9.5.5 Weak Factorization Systems

Throughout this text, we have frequently made use of the fact that every morphism 04N9
of simplicial sets $h : X \rightarrow Z$ admits a factorization $X \xrightarrow{f} Y \xrightarrow{g} Z$, where g is some sort of fibration and the morphism f has innocuous properties. In this section, we develop a general framework for results of this type.

Definition 9.5.5.1. Let $\mathcal{C}$ be an ∞ -category. A *weak factorization system on $\mathcal{C}$* is a pair 04NA
(S_L, S_R), where S_L and S_R are collections of morphisms of $\mathcal{C}$ which satisfy the following conditions:

- (1) For every morphism $h : X \rightarrow Z$ of $\mathcal{C}$, there exists a 2-simplex

$$\begin{array}{ccc} & Y & \\ f \nearrow & & \searrow g \\ X & \xrightarrow{h} & Z \end{array}$$

where f belongs to S_L and g belongs to S_R .

- (2) Every lifting problem

$$\begin{array}{ccc} A & \xrightarrow{\quad} & X \\ \downarrow f & \nearrow \quad & \downarrow g \\ B & \xrightarrow{\quad} & Y \end{array}$$

in $\mathcal{C}$ admits a solution, provided that $f \in S_L$ and $g \in S_R$.

(3) The collections S_L and S_R are closed under retracts (in the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$).

04NB **Example 9.5.5.2.** Let $\mathcal{C} = \mathrm{Set}_\Delta$ be the category of simplicial sets. We have already encountered several examples of weak factorization systems (S_L, S_R) on $\mathcal{C}$:

- We can take S_R to be the collection of Kan fibrations and S_L the collection of anodyne morphisms (Proposition 3.1.7.1).
- We can take S_R to be the collection of inner anodyne morphisms and S_L the collection of inner fibrations (Proposition 4.1.3.2).
- We can take S_R to be the collection of left fibrations and S_L the collection of left anodyne morphisms (Proposition 4.2.4.7).
- We can take S_R to be the collection of right fibrations and S_L the collection of left anodyne morphisms (Variant 4.2.4.8).
- We can take S_R to be the collection of trivial Kan fibrations and S_L the collection of monomorphisms (Exercise 3.1.7.11).

04NC **Remark 9.5.5.3** (Symmetry). Let $\mathcal{C}$ be an ∞ -category and let (S_L, S_R) be a weak factorization system on $\mathcal{C}$. Then the pair (S_R, S_L) is a weak factorization system on the opposite ∞ -category $\mathcal{C}^{\mathrm{op}}$.

04ND **Remark 9.5.5.4.** Let $\mathcal{C}$ be an ∞ -category. For every collection of morphisms S of $\mathcal{C}$, let $[S]$ be the collection of homotopy classes of morphisms which belong to S . If (S_L, S_R) is a weak factorization system on $\mathcal{C}$, then $([S_L], [S_R])$ is a weak factorization system on (the nerve of) the homotopy category $\mathrm{h}\mathcal{C}$. See Warning 9.5.4.5 and Variant 8.5.1.3.

In the situation of Definition 9.5.5.1, the collections S_L and S_R are determined by one another.

04NE **Proposition 9.5.5.5.** *Let $\mathcal{C}$ be an ∞ -category, let (S_L, S_R) be a weak factorization system on $\mathcal{C}$, and let $h : X \rightarrow Z$ be a morphism of $\mathcal{C}$. Then h belongs to S_L if and only if it is weakly left orthogonal to S_R , and h belongs to S_R if and only if it is weakly right orthogonal to S_L .*

Proof. We will prove the first assertion; the second follows by a similar argument. Assume that h is weakly left orthogonal to S_R ; we wish to show that h belongs to S_L (the reverse implication is immediate from the definition). By virtue of Remark 9.5.5.4, we may assume that $\mathcal{C}$ is (the nerve of) an ordinary category. The morphism h admits a factorization

$X \xrightarrow{f} Y \xrightarrow{g} Z$, where $f \in S_L$ and $g \in S_R$. Since h is weakly left orthogonal to g , the lifting problem

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ \downarrow h & \nearrow i & \downarrow g \\ Z & \xrightarrow{\text{id}} & Z \end{array}$$

admits a solution. We then have a commutative diagram

$$\begin{array}{ccccc} X & \xrightarrow{\text{id}} & X & \xrightarrow{\text{id}} & X \\ \downarrow h & & \downarrow f & & \downarrow h \\ Z & \xrightarrow{i} & Y & \xrightarrow{g} & Z \end{array}$$

which exhibits h as a retract of f , so that h also belongs to S_L . □

Corollary 9.5.5.6. *Let $\mathcal{C}$ be an ∞ -category and let (S_L, S_R) be a weak factorization system 04NF on $\mathcal{C}$. Then S_L is a weakly saturated collection of morphisms of $\mathcal{C}$ (see Definition 9.5.2.22).*

Proof. Combine Proposition 9.5.5.5 with Corollary 9.5.4.17. □

Using the small object argument of §9.5.3, we can produce many examples of weak factorization systems.

Theorem 9.5.5.7 (Existence of Weak Factorization Systems). *Let $\mathcal{C}$ be an ∞ -category and 04NG let W be a collection of morphisms of $\mathcal{C}$. Assume that:*

- (1) *The ∞ -category $\mathcal{C}$ is locally small and admits small colimits.*
- (2) *The collection W is small.*
- (3) *For every morphism $w : X \rightarrow Y$ in W , the object X is κ -compact for some small cardinal κ .*

Then $\mathcal{C}$ admits a weak factorization system (S_L, S_R) , where S_L is the weakly saturated collection of morphisms generated by W (Remark 9.5.2.26) and S_R is the collection of morphisms which are weakly right orthogonal to W .

Remark 9.5.5.8. Let $\mathcal{C}$ be an ∞ -category, let W be a collection of morphisms of $\mathcal{C}$, let 04NH $W_\perp$ denote the collection of morphisms of $\mathcal{C}$ which are weakly right orthogonal to every morphism of W , and let $\overline{W}$ denote the collection of all morphisms which are weakly left

orthogonal to every morphism of $W_\perp$. Then $\overline{W}$ is always a weakly saturated collection of morphisms which contains W (Corollary 9.5.4.17). If the hypotheses of Theorem 9.5.5.7 are satisfied, then $\overline{W}$ is the weakly saturated collection generated by W , in the sense of Remark 9.5.2.26.

Proof of Theorem 9.5.5.7. The collection S_L is closed under retracts by construction, and S_R is closed under retracts by virtue of Proposition 9.5.4.14. Corollary 9.5.4.17 guarantees that S_L is weakly left orthogonal to S_R . It will therefore suffice to show that every morphism $h : X \rightarrow Z$ of $\mathcal{C}$ factors as a composition $X \xrightarrow{f} Y \xrightarrow{g} Z$, where f belongs to S_L and g belongs to S_R .

Let $\tilde{\mathcal{C}}$ denote the slice ∞ -category $\mathcal{C}_{/Z}$, and let $\pi : \tilde{\mathcal{C}} \rightarrow \mathcal{C}$ denote the projection map. Our assumption that $\mathcal{C}$ is locally small guarantees that $\tilde{\mathcal{C}}$ is also locally small (Example 4.7.8.11), and our assumption that $\mathcal{C}$ admits small colimits guarantees that $\tilde{\mathcal{C}}$ admits small colimits (Corollary 7.1.4.22). Let $\tilde{W}$ denote a set of representatives for the collection of isomorphism classes of morphisms $\tilde{w}$ of $\mathcal{C}_{/Z}$ satisfying $\pi(\tilde{w}) \in W$. Since W is small and $\mathcal{C}$ is locally small, the set $\tilde{W}$ is also small. For every morphism $\tilde{w} : \tilde{A} \rightarrow \tilde{B}$ which belongs to $\tilde{W}$, the image $A = \pi(\tilde{A})$ is a κ -compact object of $\tilde{\mathcal{C}}$ for some small cardinal κ , so that $\tilde{A}$ is a κ -compact object of $\tilde{\mathcal{C}}$ (Remark [?]). Let us identify the morphism h with an object $\tilde{X} \in \tilde{\mathcal{C}}$ satisfying $\pi(\tilde{X}) = X$. Applying Theorem 9.5.3.3, we deduce that there is a morphism $\tilde{f} : \tilde{X} \rightarrow \tilde{Y}$ in the ∞ -category $\tilde{\mathcal{C}}$ which is a transfinite pushout of morphisms of $\tilde{W}$, where $\tilde{Y}$ is $\tilde{W}$ -local. Set $f = \pi(\tilde{f})$, so that f can be identified with a diagram

$$\begin{array}{ccc} & Y & \\ f \nearrow & & \searrow g \\ X & \xrightarrow{h} & Z \end{array}$$

in the ∞ -category $\mathcal{C}$. Since the functor π preserves small colimits (Corollary 7.1.4.22), the morphism f is a transfinite pushout of morphisms belonging to W , and therefore belongs to S_L . Our assumption that $\tilde{Y}$ is $\tilde{W}$ -local guarantees that g belongs to S_R (Remark 9.5.4.12). $\square$

9.5.6 Orthogonality

04NJ In the ∞ -categorical setting, it will often be useful to view the collection of solutions to a lifting problem as a space, rather than a set.

Construction 9.5.6.1. Suppose we are given a lifting problem

04NK

$$\begin{array}{ccc} A & \xrightarrow{\quad} & X \\ \downarrow f & \nearrow \text{---} & \downarrow g \\ B & \xrightarrow{\quad} & Y \end{array}$$

in an ∞ -category $\mathcal{C}$, given by a morphism $\sigma : \Delta^1 \times \Delta^1 \rightarrow \mathcal{C}$. We let $\text{Sol}(\sigma)$ denote the simplicial set $\{\sigma\} \times_{\text{Fun}(Q, \mathcal{C})} \text{Fun}(\Delta^3, \mathcal{C})$, where $Q \subset \Delta^3$ is the simplicial subset described in Remark 9.5.4.2. We will refer to $\text{Sol}(\sigma)$ as the *space of solutions* to the lifting problem σ .

Remark 9.5.6.2. In the situation of Construction 9.5.6.1, vertices of the simplicial set $\text{Sol}(\sigma)$ can be identified with solutions to the lifting problem σ (in the sense of Definition 9.5.4.1). In particular, the lifting problem σ admits a solution if and only if $\text{Sol}(\sigma)$ is nonempty.

Remark 9.5.6.3. In the situation of Construction 9.5.6.1, the restriction map $\text{Fun}(\Delta^3, \mathcal{C}) \rightarrow \text{Fun}(Q, \mathcal{C})$ is an isofibration of ∞ -categories (Corollary 4.4.5.3). Moreover, since Q contains every vertex of Δ^3 , it is also conservative (Theorem 4.4.4.4). It follows that the solution space $\text{Sol}(\sigma)$ is a Kan complex (Corollary 4.4.3.22).

Definition 9.5.6.4. Let $\mathcal{C}$ be an ∞ -category, and let $f : A \rightarrow B$ and $g : X \rightarrow Y$ be morphisms of $\mathcal{C}$. We will say that f is *left orthogonal* to g if, for every lifting problem σ :

$$\begin{array}{ccc} A & \xrightarrow{\quad} & X \\ \downarrow f & \nearrow \text{---} & \downarrow g \\ B & \xrightarrow{\quad} & Y \end{array}$$

in the ∞ -category $\mathcal{C}$, the solution space $\text{Sol}(\sigma)$ is a contractible Kan complex. In this case, we will also say that g is *right orthogonal* to f .

Example 9.5.6.5. Let $\mathcal{C}$ be an ordinary category. Then a morphism $f : A \rightarrow B$ is left orthogonal to a morphism $g : X \rightarrow Y$ in the ∞ -category $\mathbf{N}_\bullet(\mathcal{C})$ if and only if every lifting problem

$$\begin{array}{ccc} A & \xrightarrow{u_0} & X \\ \downarrow f & \nearrow \text{---} & \downarrow g \\ B & \xrightarrow{\bar{u}} & Y \end{array}$$

admits a *unique* solution: that is, there is a unique morphism $u : B \rightarrow X$ satisfying $u \circ f = u_0$ and $g \circ u = \bar{u}$.

04NQ **Remark 9.5.6.6.** Let f and g be morphisms in an ∞ -category $\mathcal{C}$. Then f is left orthogonal to g in $\mathcal{C}$ if and only if it is right orthogonal to g when regarded as a morphism of the opposite ∞ -category $\mathcal{C}^{\text{op}}$.

04NR **Remark 9.5.6.7.** Let f and g be morphisms in an ∞ -category $\mathcal{C}$. If f is left orthogonal to g (in the sense of Definition 9.5.6.4), then it is weakly left orthogonal to g (in the sense of Definition 9.5.4.8). Beware that the converse is false (Exercise 9.5.6.8).

04NS **Exercise 9.5.6.8.** Let $f : A \twoheadrightarrow B$ be a surjective function between sets, and let $g : X \hookrightarrow Y$ be an injective function between sets. Show that:

- The morphism f is left orthogonal to g (in the category of sets).
- The morphism g is weakly left orthogonal to f .
- Unless either f or g is a bijection, the morphism g is not left orthogonal to f .

04NT **Variant 9.5.6.9.** Let $\mathcal{C}$ be an ∞ -category and let S and T be collections of morphisms of $\mathcal{C}$. We say that S is *left orthogonal to* T if every morphism $f \in S$ is weakly left orthogonal to every morphism $g \in T$. In this case, we also say that T is *right orthogonal to* S . In the special case where $S = \{f\}$ is a singleton, we abbreviate this condition by saying that f is *left orthogonal to* T , or T is *right orthogonal to* f . In the special case $T = \{g\}$ is a singleton, we abbreviate this condition by saying that g is *right orthogonal to* S , or S is *left orthogonal to* g .

To establish some elementary properties of Definition 9.5.6.4, it will be convenient to give an alternative description of the solution spaces $\text{Sol}(\sigma)$.

04NU **Construction 9.5.6.10.** Let $\mathcal{C}$ be an ∞ -category and let $\sigma :$

$$\begin{array}{ccc} A & \xrightarrow{\quad} & X \\ \downarrow f & \nearrow & \downarrow g \\ B & \xrightarrow{\quad} & Y \end{array}$$

be a lifting problem in $\mathcal{C}$. Then σ determines a pair of objects $\tilde{B}, \tilde{X}$ in the ∞ -category $\mathcal{C}_{A//Y}$ (see Remark 9.5.4.7). Let K denote the morphism space $\text{Hom}_{\mathcal{C}_{A//Y}}(\tilde{B}, \tilde{X})$. We then have a tautological map $K \times \Delta^1 \rightarrow \mathcal{C}_{A//Y}$, which we can identify with a diagram $\{A\} \star (K \times \Delta^1) \star \{Y\} \rightarrow \mathcal{C}$. Composing with the quotient map

$$K \times \Delta^3 \simeq K \times (\{A\} \star \Delta^1 \star \{Y\}) \twoheadrightarrow \{A\} \star (K \times \Delta^1) \star \{Y\},$$

we obtain a morphism $K \rightarrow \text{Fun}(\Delta^3, \mathcal{C})$, which factors through the simplicial subset $\text{Sol}(\sigma) \subseteq \text{Fun}(\Delta^3, \mathcal{C})$ of Construction 9.5.6.1. We therefore obtain a comparison map $\theta : \text{Hom}_{\mathcal{C}_{A//Y}}(\tilde{B}, \tilde{X}) \rightarrow \text{Sol}(\sigma)$.

Proposition 9.5.6.11. *Let $\mathcal{C}$ be an ∞ -category and let $\sigma :$*

04NV

$$\begin{array}{ccc} A & \xrightarrow{\quad} & X \\ \downarrow & \nearrow \text{dashed} & \downarrow \\ B & \xrightarrow{\quad} & Y \end{array}$$

04NW

(9.24)

be a lifting problem in $\mathcal{C}$. Then the comparison map

$$\theta : \mathrm{Hom}_{\mathcal{C}_{A/Y}}(\tilde{B}, \tilde{X}) \rightarrow \mathrm{Sol}(\sigma)$$

of Construction 9.5.6.10 is a homotopy equivalence of Kan complexes.

Proof. Corollary 4.6.6.9 supplies a categorical pullback diagram of ∞ -categories

$$\begin{array}{ccc} \mathrm{Fun}(\Delta^1, \mathcal{C}_{A/Y}) & \longrightarrow & \mathrm{Fun}(\{A\} \star \Delta^1 \star \{Y\}, \mathcal{C}) \\ \downarrow & & \downarrow \\ \mathrm{Fun}(\partial\Delta^1, \mathcal{C}_{A/Y}) & \longrightarrow & \mathrm{Fun}(\{A\} \star \partial\Delta^1 \star \{Y\}, \mathcal{C}), \end{array}$$

where the vertical maps are isofibrations (Corollary 4.4.5.3). Unwinding the definitions, we see that the comparison map θ is obtained by taking vertical fibers over the vertex corresponding to the pair $(\tilde{B}, \tilde{X})$. Corollary 4.5.2.32 guarantees that θ is an equivalence of ∞ -categories. Since the source and target of θ are Kan complexes (Remark 9.5.6.3), it is a homotopy equivalence (Example 4.5.1.13). $\square$

Warning 9.5.6.12. In the situation of Proposition 9.5.6.11, the comparison map θ need not be an isomorphism of simplicial sets. However, it is always bijective on 0-simplices: vertices of both $\mathrm{Hom}_{\mathcal{C}_{A/Y}}(\tilde{B}, \tilde{X})$ and $\mathrm{Sol}(\sigma)$ can be identified with solutions to the lifting problem σ . 04NX

Remark 9.5.6.13. Let $\mathcal{C}$ be an ∞ -category containing a morphism $w : X \rightarrow Y$. Let $\pi : \mathcal{C}_{X/} \rightarrow \mathcal{C}$ denote the projection map, so that w can be identified with an object $\tilde{Y} \in \mathcal{C}_{X/}$ satisfying $\pi(\tilde{Y}) = Y$. Then an object $C \in \mathcal{C}$ is w -local (in the sense of Definition 6.2.3.1) if and only if, for every object $\tilde{C} \in \mathcal{C}_{X/}$ satisfying $\pi(\tilde{C}) = C$, the morphism space $\mathrm{Hom}_{\mathcal{C}_{X/}}(\tilde{Y}, \tilde{C})$ is contractible. This follows from the criterion of Remark 3.4.0.6, since $\mathrm{Hom}_{\mathcal{C}_{X/}}(\tilde{Y}, \tilde{C})$ can be identified with the homotopy fiber of the composition map $\mathrm{Hom}_{\mathcal{C}}(Y, C) \rightarrow \mathrm{Hom}_{\mathcal{C}}(X, C)$ over the vertex corresponding to $\tilde{C}$ (see Corollary 4.6.9.18). 04KJ

04NY **Corollary 9.5.6.14.** *Let $\mathcal{C}$ be an ∞ -category containing morphisms $f : A \rightarrow B$ and $g : X \rightarrow Y$. Let $\pi : \mathcal{C}_{/Y} \rightarrow \mathcal{C}$ denote the projection map, so that g can be identified with an object $\tilde{X} \in \mathcal{C}_{/Y}$ satisfying $\pi(\tilde{X}) = X$. The following conditions are equivalent:*

- (1) *The morphism g is right orthogonal to f (in the sense of Definition 9.5.6.4).*
- (2) *For every morphism $\tilde{f} : \tilde{A} \rightarrow \tilde{B}$ of $\mathcal{C}_{/Y}$ satisfying $\pi(\tilde{f}) = f$, the object $\tilde{X} \in \mathcal{C}_{/Y}$ is $\tilde{f}$ -local (in the sense of Definition 6.2.3.1).*

Proof. Combine Proposition 9.5.6.11 with Remark 9.5.6.13. $\square$

04NZ **Corollary 9.5.6.15.** *Let $\mathcal{C}$ be an ∞ -category containing morphisms $f : A \rightarrow B$ and $g : X \rightarrow Y$. If either f or g is an isomorphism, then f is left orthogonal to g .*

Proof. Without loss of generality, we may assume that f is an isomorphism. Let $\pi : \mathcal{C}_{/Y} \rightarrow \mathcal{C}$ be the projection map, so that we can identify g with an object $\tilde{X} \in \mathcal{C}_{/Y}$ satisfying $\pi(\tilde{X}) = X$. By virtue of Corollary 9.5.6.14, it will suffice to show that $\tilde{X}$ is $\tilde{f}$ -local for every morphism $\tilde{f}$ of $\mathcal{C}_{/Y}$ satisfying $\pi(\tilde{f}) = f$. This is a special case of Example 6.2.3.2, since $\tilde{f}$ is an isomorphism (Proposition 4.4.2.11). $\square$

04P0 **Corollary 9.5.6.16.** *Let $\mathcal{C}$ be an ∞ -category containing a morphism $g : X \rightarrow Y$ and a 2-simplex*

04P1

$$\begin{array}{ccc}
 & B & \\
 f' \nearrow & & \searrow f'' \\
 A & \xrightarrow{f} & C.
 \end{array} \tag{9.25}$$

Assume that f' is left orthogonal to g . Then f is left orthogonal to g if and only if f'' is left orthogonal to g .

Proof. Assume that f'' is left orthogonal to g ; we will show that f is left orthogonal to g (the proof of the converse is similar). Let $\pi : \mathcal{C}_{/Y} \rightarrow \mathcal{C}$ be the projection map, so that we can identify g with an object $\tilde{X} \in \mathcal{C}_{/Y}$ satisfying $\pi(\tilde{X}) = X$. By virtue of Corollary 9.5.6.14, it will suffice to show that the object $\tilde{X}$ is $\tilde{f}$ -local, for every morphism $\tilde{f}$ of $\mathcal{C}_{/Y}$ satisfying $\pi(\tilde{f}) = f$. Since π is a right fibration (Proposition 4.3.6.1), we can lift (9.25) to a diagram

$$\begin{array}{ccc}
 & \tilde{B} & \\
 \tilde{f}' \nearrow & & \searrow \tilde{f}'' \\
 \tilde{A} & \xrightarrow{\tilde{f}} & \tilde{C}
 \end{array}$$

in the ∞ -category $\mathcal{C}_{/Y}$. Corollary 9.5.6.14 guarantees that the object $\tilde{X}$ is both $\tilde{f}'$ -local and $\tilde{f}''$ -local, so the desired result follows from Remark 6.2.3.6. $\square$

Warning 9.5.6.17. In the situation of Corollary 9.5.6.16, if the morphisms f and f'' are left orthogonal to g , then f' need not be left orthogonal to g . 04P2

Corollary 9.5.6.18. Let $\mathcal{C}$ be an ∞ -category and let $g : X \rightarrow Y$ be a morphism of $\mathcal{C}$. If another morphism $f : A \rightarrow B$ is left orthogonal to g , then any retract of f (in the ∞ -category $\text{Fun}(\Delta^1, \mathcal{C})$) is also left orthogonal to g . 04P3

Proof. We proceed as in the proof of Proposition 9.5.4.14. Let $f' : A' \rightarrow B'$ be a retract of f (in the ∞ -category $\text{Fun}(\Delta^1, \mathcal{C})$); we will show that f' is left orthogonal to g . Let $\pi : \mathcal{C}_{/Y} \rightarrow \mathcal{C}$ be the projection map, and let us identify g with an object $\tilde{X} \in \mathcal{C}_{/Y}$ satisfying $\pi(\tilde{X}) = X$. By virtue of Corollary 9.5.6.14, it will suffice to show that for any morphism $\tilde{f}'$ of $\mathcal{C}_{/Y}$ satisfying $\pi(\tilde{f}') = f'$, the object $\tilde{X}$ is $\tilde{f}'$ -local. It follows from Corollary 4.2.5.2 that π induces a right fibration $\text{Fun}(\Delta^1, \mathcal{C}_{/Y}) \rightarrow \text{Fun}(\Delta^1, \mathcal{C})$. Applying Remark 8.5.1.23, we deduce that $\tilde{f}'$ is a retract of a morphism $\tilde{f}$ of $\mathcal{C}_{/Y}$ satisfying $U(\tilde{f}) = f$. By virtue of Variant 9.5.2.13, it will suffice to show that the object $\tilde{X}$ is $\tilde{f}$ -local, which follows from our assumption that f is left orthogonal to g (Corollary 9.5.6.14). $\square$

Corollary 9.5.6.19. Let $\mathcal{C}$ be an ∞ -category containing a pushout diagram 04P4

$$\begin{array}{ccc} A & \longrightarrow & A' \\ \downarrow f & & \downarrow f' \\ B & \longrightarrow & B' \end{array}$$

(9.26)

04P5

If f is left orthogonal to a morphism $g : X \rightarrow Y$ of $\mathcal{C}$, then f' is also left orthogonal to g .

Proof. We proceed as in the proof of Proposition 9.5.4.15. Let $\pi : \mathcal{C}_{/Y} \rightarrow \mathcal{C}$ be the projection map, and let us identify g with an object $\tilde{X} \in \mathcal{C}_{/Y}$ satisfying $\pi(\tilde{X}) = X$. By virtue of Corollary 9.5.6.14, it will suffice to show that for any morphism $\tilde{f}'$ of $\mathcal{C}_{/Y}$ satisfying $\pi(\tilde{f}') = f'$, the object $\tilde{X}$ is weakly $\tilde{f}'$ -local. Since π is a right fibration, we can lift (9.26) to a diagram

$$\begin{array}{ccc} \tilde{A} & \longrightarrow & \tilde{A}' \\ \downarrow \tilde{f} & & \downarrow \tilde{f}' \\ \tilde{B} & \longrightarrow & \tilde{B}' \end{array}$$

in the ∞ -category $\mathcal{C}_{/Y}$, which is also a pushout square (Proposition 7.1.4.21). By virtue of Variant 9.5.2.15, it will suffice to show that $\tilde{X}$ is $\tilde{f}$ -local, which follows from our assumption that f is left orthogonal to g (Corollary 9.5.6.14). $\square$

04P6 **Corollary 9.5.6.20.** *Let $\mathcal{C}$ be an ∞ -category, and let f be a morphism of $\mathcal{C}$ which is the colimit of a diagram*

$$Q_0 : K \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C}) \quad v \mapsto f_v$$

which is preserved by the evaluation functors $\mathrm{ev}_0, \mathrm{ev}_1 : \mathrm{Fun}(\Delta^1, \mathcal{C}) \rightarrow \mathcal{C}$. Let $g : X \rightarrow Y$ be a morphism which is right orthogonal to each of the morphisms f_v . Then g is right orthogonal to f .

Proof. Let $\pi : \mathcal{C}_{/Y} \rightarrow \mathcal{C}$ be the projection map, and let us identify g with an object $\tilde{X} \in \mathcal{C}_{/Y}$ satisfying $\pi(\tilde{X}) = X$. By virtue of Corollary 9.5.6.14, it will suffice to show that if $\tilde{f}$ is a morphism in $\mathcal{C}_{/Y}$ satisfying $\pi(\tilde{f}) = f$, then $\tilde{X}$ is $\tilde{f}$ -local. Choose a colimit diagram $Q : K^\triangleright \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C})$ which satisfies $Q|_K = Q_0$ and carries the cone point of $K^\triangleright$ to f . Since the inclusion of the cone point into $K^\triangleright$ is right anodyne (Example 4.3.7.11) and the projection map $\mathrm{Fun}(\Delta^1, \mathcal{C}_{/Y}) \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C})$ is a right fibration (Corollary 4.2.5.2) we can lift Q to a diagram $\tilde{Q} : K^\triangleright \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C})$ carrying the cone point to $\tilde{f}$. Using Corollary 7.1.4.22 and Proposition 7.1.8.3, we see that $\tilde{Q}$ is a colimit diagram which is preserved by the evaluation functors $\mathrm{ev}_0, \mathrm{ev}_1 : \mathrm{Fun}(\Delta^1, \mathcal{C}_{/Y}) \rightarrow \mathcal{C}_{/Y}$. For each vertex $v \in K$, let $\tilde{f}_v = \tilde{Q}(v)$ is a morphism of $\mathcal{C}_{/Y}$ satisfying $\pi(\tilde{f}_v) = f_v$. Our assumption that f_v is left orthogonal to g guarantees that $\tilde{X}$ is a $\tilde{f}_v$ -local object of the ∞ -category $\mathcal{C}_{/Y}$ (Corollary 9.5.6.14). Applying Remark 7.4.1.21, we deduce that $\tilde{X}$ is also $\tilde{f}$ -local. $\square$

04P7 **Corollary 9.5.6.21.** *Let $\mathcal{C}$ be an ∞ -category, let $g : X \rightarrow Y$ be a morphism of $\mathcal{C}$, and let S be the collection of morphisms of $\mathcal{C}$ which are left orthogonal to g . Then S is weakly saturated.*

Proof. Combining Corollaries 9.5.6.15, 9.5.6.16, and 9.5.6.20 with Proposition 9.5.1.10 (and Remark 9.5.1.11), we see that S is closed under transfinite composition. Since S is also closed under retracts (Corollary 9.5.6.18) and pushouts (Corollary 9.5.6.19), it is weakly saturated. $\square$

04P8 **Corollary 9.5.6.22.** *Let $\mathcal{C}$ be an ∞ -category, let S be a collection of morphisms of $\mathcal{C}$, and let $g : X \rightarrow Y$ be a morphism of $\mathcal{C}$ which is weakly right orthogonal to S . Assume that every morphism $f : A \rightarrow B$ which belongs to S admits a relative codiagonal $\gamma_{A/B} : B \amalg_A B \rightarrow B$ which also belongs to S (see Variant 7.6.2.16). Then g is right orthogonal to S .*

Proof. Let $\pi : \mathcal{C}_{/Y} \rightarrow \mathcal{C}$ be the projection map, and let us identify g with an object $\tilde{X} \in \mathcal{C}_{/Y}$ satisfying $\pi(\tilde{X}) = X$. Let $\tilde{S}$ denote the collection of those morphisms $\tilde{f}$ in $\mathcal{C}_{/Y}$ which satisfy $\pi(\tilde{f}) \in S$. Our assumption that g is weakly right orthogonal to S guarantees that $\tilde{X}$ is

weakly $\tilde{S}$ -local (Remark 9.5.4.12). It follows from Proposition 7.1.4.21 that every morphism of $\tilde{S}$ admits a relative codiagonal which also belongs to $\tilde{S}$, so that $\tilde{X}$ is $\tilde{S}$ -local (Proposition 9.5.2.18). Invoking Corollary 9.5.6.14, we conclude that g is right orthogonal to S . $\square$

Proposition 9.5.6.23. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of ∞ -categories, let $\sigma :$* 04P9

$$\begin{array}{ccc} A & \xrightarrow{\quad} & X \\ \downarrow f & \nearrow \text{dashed} & \downarrow g \\ B & \xrightarrow{\quad} & Y \end{array} \quad (9.27) \quad \text{04PA}$$

be a lifting problem in the ∞ -category $\mathcal{E}$, and let $\bar{\sigma} = U \circ \sigma$ denote the associated lifting problem in the ∞ -category $\mathcal{C}$. If the morphism f is U -cocartesian or the morphism g is U -cartesian, then U induces a homotopy equivalence of solution spaces $\text{Sol}(\sigma) \rightarrow \text{Sol}(\bar{\sigma})$.

Proof. Let us identify the diagram (9.27) with a pair of objects $\tilde{B}, \tilde{X} \in \mathcal{E}_{A/Y}$. Note that U induces a functor $\tilde{U} : \mathcal{E}_{A/Y} \rightarrow \mathcal{C}_{U(A)/U(Y)}$, and we have a commutative diagram

$$\begin{array}{ccc} \text{Hom}_{\mathcal{E}_{A/Y}}(\tilde{B}, \tilde{X}) & \xrightarrow{\quad} & \text{Sol}(\sigma) \\ \downarrow & & \downarrow \\ \text{Hom}_{\mathcal{C}_{U(A)/U(Y)}}(\tilde{U}(\tilde{B}), \tilde{U}(\tilde{X})) & \xrightarrow{\quad} & \text{Sol}(\bar{\sigma}), \end{array}$$

where the horizontal maps are the homotopy equivalences supplied by Proposition 9.5.6.11. It will therefore suffice to show that the left vertical map is a homotopy equivalence. Without loss of generality, we may assume that the morphism f is U -cocartesian. In this case, we will complete the proof by showing that the object $\tilde{B} \in \mathcal{E}_{A/Y}$ is $\tilde{U}$ -initial. Let $U_{/Y} : \mathcal{E}_{/Y} \rightarrow \mathcal{C}_{/U(Y)}$ be the inner fibration induced by U ; by virtue of Example 7.1.7.2, it will suffice to show that the lower left of the diagram (9.27) is $U_{/Y}$ -cocartesian when viewed as a morphism in $\mathcal{E}_{/Y}$. This follows from our assumption that f is U -cocartesian (Corollary 5.1.1.15). $\square$

Corollary 9.5.6.24. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be an inner fibration of ∞ -categories and let f and g* 04PB
be morphisms of $\mathcal{E}$. Assume either that f is U -cocartesian or that g is U -cartesian. Then:

- If $U(f)$ is left orthogonal to $U(g)$ in the ∞ -category $\mathcal{C}$, then f is left orthogonal to g in the ∞ -category $\mathcal{E}$.
- If $U(f)$ is weakly left orthogonal to $U(g)$ in the ∞ -category $\mathcal{C}$, then f is weakly left orthogonal to g in the ∞ -category $\mathcal{E}$.

9.5.7 Uniqueness of Factorizations

04PQ Let $\mathcal{C}$ be an ∞ -category, let S_L and S_R be collections of morphisms of $\mathcal{C}$, and let $f : X \rightarrow Z$ be a morphism which factors as a composition

$$X \xrightarrow{f_L} Y \xrightarrow{f_R} Z$$

where f_L belongs to S_L and f_R belongs to S_R . Our goal in this section is to show that, if S_L is left orthogonal to S_R , then this factorization is essentially unique (Theorem 9.5.7.2).

04PS **Notation 9.5.7.1.** Let $\mathcal{C}$ be an ∞ -category and let S_L and S_R be collections of morphisms of $\mathcal{C}$. We let $\mathrm{Fun}_L(\Delta^2, \mathcal{C})$ denote the full subcategory of $\mathrm{Fun}(\Delta^2, \mathcal{C})$ spanned by those diagrams

$$\begin{array}{ccc} & Y & \\ f_L \nearrow & & \searrow f_R \\ X & \xrightarrow{f} & Z \end{array}$$

where f belongs to S_L , and $\mathrm{Fun}_R(\Delta^2, \mathcal{C})$ the full subcategory of $\mathrm{Fun}(\Delta^2, \mathcal{C})$ spanned by those diagrams where g belongs to S_R . We let $\mathrm{Fun}_{LR}(\Delta^2, \mathcal{C})$ denote the intersection $\mathrm{Fun}_L(\Delta^2, \mathcal{C}) \cap \mathrm{Fun}_R(\Delta^2, \mathcal{C})$.

We can now formulate our main result.

04QC **Theorem 9.5.7.2.** Let $\mathcal{C}$ be an ∞ -category and let S_L and S_R be collections of morphisms of $\mathcal{C}$. If S_L is left orthogonal to S_R , then the restriction functor

$$D : \mathrm{Fun}_{LR}(\Delta^2, \mathcal{C}) \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C}) \quad \sigma \mapsto d_1^2(\sigma)$$

is fully faithful. The converse holds if S_L and S_R contain all identity morphisms of $\mathcal{C}$.

The proof of Theorem 9.5.7.2 will require some preliminaries. We begin by giving another description of the space of solutions to a lifting problem.

04PW **Notation 9.5.7.3.** Let $\mathcal{C}$ be an ∞ -category containing morphisms $f : A \rightarrow B$ and $g : X \rightarrow Y$. We let ${}_f\mathrm{Fun}(\Delta^3, \mathcal{C})_g$ denote the iterated fiber product

$$\{f\} \times_{\mathrm{Fun}(\mathbf{N}_\bullet, \{0 < 1\})} \mathrm{Fun}(\Delta^3, \mathcal{C}) \times_{\mathrm{Fun}(\mathbf{N}_\bullet, \{2 < 3\})} \{g\},$$

whose objects can be identified with diagrams

$$\begin{array}{ccc} A & \xrightarrow{\quad} & X \\ \downarrow f & \nearrow & \downarrow g \\ B & \xrightarrow{\quad} & Y \end{array}$$

in the ∞ -category $\mathcal{C}$.

Lemma 9.5.7.4. *Let $\mathcal{C}$ be an ∞ -category containing morphisms $f : A \rightarrow B$ and $g : X \rightarrow Y$. 04PX Then precomposition with the inclusion map $N_\bullet(\{1 < 2\}) \hookrightarrow \Delta^3$ induces a trivial Kan fibration of simplicial sets ${}_f\mathrm{Fun}(\Delta^3, \mathcal{C})_g \rightarrow \mathrm{Hom}_{\mathcal{C}}(B, X)$. In particular, the simplicial set ${}_f\mathrm{Fun}(\Delta^3, \mathcal{C})_g$ is a Kan complex.*

Proof. By construction, we have a pullback diagram of simplicial sets

$$\begin{array}{ccc} {}_f\mathrm{Fun}(\Delta^3, \mathcal{C})_g & \longrightarrow & \mathrm{Fun}(\Delta^3, \mathcal{C}) \\ \downarrow & & \downarrow \\ \mathrm{Hom}_{\mathcal{C}}(B, X) & \longrightarrow & \mathrm{Fun}(\mathrm{Spine}[3], \mathcal{C}), \end{array}$$

where the right vertical map is a trivial Kan fibration (see Example 1.5.7.7). $\square$

Notation 9.5.7.5. Let $\mathcal{C}$ be an ∞ -category containing morphisms $f : A \rightarrow B$ and $g : X \rightarrow Y$. 04PY We let $\tilde{f} = s_1^1(f)$ and $\tilde{g} = s_0^1(g)$ denote the degenerate 2-simplices of $\mathcal{C}$ depicted in the diagram

$$A \xrightarrow{f} B \xrightarrow{\mathrm{id}} B \quad X \xrightarrow{\mathrm{id}} X \xrightarrow{g} Y.$$

Let $\beta : \Delta^2 \times \Delta^1 \rightarrow \Delta^3$ denote the morphism of simplicial sets given on vertices by the formulae

$$\beta(0, 0) = 0 \quad \beta(1, 0) = 1 = \beta(2, 0) \quad \beta(0, 1) = 2 = \beta(1, 1) \quad \beta(2, 1) = 3.$$

Then precomposition with β determines a functor $\mathrm{Fun}(\Delta^3, \mathcal{C}) \rightarrow \mathrm{Fun}(\Delta^2 \times \Delta^1, \mathcal{C})$, which restricts to a map of Kan complexes $T : {}_f\mathrm{Fun}(\Delta^3, \mathcal{C})_g \rightarrow \mathrm{Hom}_{\mathrm{Fun}(\Delta^2, \mathcal{C})}(\tilde{f}, \tilde{g})$. Concretely, T carries a 3-simplex

$$\begin{array}{ccc} A & \xrightarrow{u} & X \\ \downarrow f & \nearrow v & \downarrow g \\ B & \xrightarrow{w} & Y \end{array}$$

to the morphism in $\mathrm{Fun}(\Delta^2, \mathcal{C})$ depicted in the diagram

$$\begin{array}{ccccc} A & \xrightarrow{f} & B & \xrightarrow{\mathrm{id}_B} & B \\ \downarrow u & & \downarrow v & & \downarrow w \\ X & \xrightarrow{\mathrm{id}_X} & X & \xrightarrow{g} & Y. \end{array}$$

04PZ **Lemma 9.5.7.6.** *Let $\mathcal{C}$ be an ∞ -category containing morphisms $f : A \rightarrow B$ and $g : X \rightarrow Y$. Then the comparison map*

$$T : {}_f\mathrm{Fun}(\Delta^3, \mathcal{C})_g \rightarrow \mathrm{Hom}_{\mathrm{Fun}(\Delta^2, \mathcal{C})}(\tilde{f}, \tilde{g})$$

of Notation 9.5.7.5 is a homotopy equivalence.

Proof. By construction, the diagram $\tilde{f} : \Delta^2 \rightarrow \mathcal{C}$ is left Kan extended from the simplicial subset $\Delta^1 \subset \Delta^2$. Applying Corollary 7.3.6.9, we deduce that the restriction functor $\mathrm{Fun}(\Delta^2, \mathcal{C}) \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C})$ determines a trivial Kan fibration $R : \mathrm{Hom}_{\mathrm{Fun}(\Delta^2, \mathcal{C})}(\tilde{f}, \tilde{g}) \rightarrow \mathrm{Hom}_{\mathrm{Fun}(\Delta^1, \mathcal{C})}(f, \mathrm{id}_X)$. Similarly, the 1-simplex id_X can be viewed as a diagram $\Delta^1 \rightarrow \mathcal{C}$ which is right Kan extended from the vertex $\{1\} \subset \Delta^2$, so the evaluation functor $\mathrm{ev}_1 : \mathrm{Fun}(\Delta^1, \mathcal{C}) \rightarrow \mathcal{C}$ induces a trivial Kan fibration $Q : \mathrm{Hom}_{\mathrm{Fun}(\Delta^1, \mathcal{C})}(f, \mathrm{id}_X) \rightarrow \mathrm{Hom}_{\mathcal{C}}(B, X)$. We are therefore reduced to showing that the composite map

$${}_f\mathrm{Fun}(\Delta^3, \mathcal{C})_g \xrightarrow{T} \mathrm{Hom}_{\mathrm{Fun}(\Delta^2, \mathcal{C})}(\tilde{f}, \tilde{g}) \xrightarrow{R} \mathrm{Hom}_{\mathrm{Fun}(\Delta^1, \mathcal{C})}(f, \mathrm{id}_X) \xrightarrow{Q} \mathrm{Hom}_{\mathcal{C}}(B, X)$$

is a homotopy equivalence, which follows from Lemma 9.5.7.4. $\square$

In the situation of Lemma 9.5.7.6, restriction to the “long edge” of Δ^2 determines an inner fibration of ∞ -categories $\mathrm{Fun}(\Delta^2, \mathcal{C}) \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C})$ (Corollary 4.1.4.2), and therefore induces a Kan fibration of mapping spaces

$$\mathrm{Hom}_{\mathrm{Fun}(\Delta^2, \mathcal{C})}(\tilde{f}, \tilde{g}) \rightarrow \mathrm{Hom}_{\mathrm{Fun}(\Delta^1, \mathcal{C})}(f, g).$$

04Q0 **Lemma 9.5.7.7.** *Let $\mathcal{C}$ be an ∞ -category containing a lifting problem σ :*

04Q1

$$\begin{array}{ccc} A & \xrightarrow{\quad} & X \\ \downarrow f & \nearrow s & \downarrow g \\ B & \xrightarrow{\quad} & Y, \end{array} \quad (9.28)$$

which we identify with a morphism from f to g in the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$. Then the comparison map $T : {}_f\mathrm{Fun}(\Delta^3, \mathcal{C})_g \rightarrow \mathrm{Hom}_{\mathrm{Fun}(\Delta^2, \mathcal{C})}(\tilde{f}, \tilde{g})$ of Notation 9.5.7.5 restricts to a homotopy equivalence of Kan complexes

$$T_0 : \mathrm{Sol}(\sigma) \rightarrow \mathrm{Hom}_{\mathrm{Fun}(\Delta^2, \mathcal{C})}(\tilde{f}, \tilde{g}) \times_{\mathrm{Hom}_{\mathrm{Fun}(\Delta^1, \mathcal{C})}(f, g)} \{\sigma\}.$$

Proof. Let $\alpha : \Delta^1 \times \Delta^1 \hookrightarrow \Delta^3$ be the morphism of simplicial sets given on vertices by the formula $\alpha(i, j) = 2i + j$ (see Definition 9.5.4.1). Then precomposition with α induces an isofibration of ∞ -categories $U : \mathrm{Fun}(\Delta^3, \mathcal{C}) \rightarrow \mathrm{Fun}(\Delta^1 \times \Delta^1, \mathcal{C})$, which restricts to an

isofibration $U_0 : {}_f\mathrm{Fun}(\Delta^3, \mathcal{C})_g \rightarrow \mathrm{Hom}_{\mathrm{Fun}(\Delta^1, \mathcal{C})}(f, g)$. Since the source and target of U_0 are Kan complexes, it is a Kan fibration (Corollary 4.4.3.10). The desired result now follows by applying Corollary 3.3.7.5 to the diagram of Kan complexes

$$\begin{array}{ccc} {}_f\mathrm{Fun}(\Delta^3, \mathcal{C})_g & \xrightarrow{T} & \mathrm{Hom}_{\mathrm{Fun}(\Delta^2, \mathcal{C})}(\tilde{f}, \tilde{g}) \\ & \searrow U_0 & \swarrow \\ & \mathrm{Hom}_{\mathrm{Fun}(\Delta^1, \mathcal{C})}(f, g), & \end{array}$$

since T is a homotopy equivalence (Lemma 9.5.7.6). $\square$

Corollary 9.5.7.8. *Let $\mathcal{C}$ be an ∞ -category containing 2-simplices σ and τ . Suppose that the initial edge $f = d_2^2(\sigma)$ is left orthogonal to the final edge $g = d_0^2(\tau)$. Then the restriction map $\theta : \mathrm{Hom}_{\mathrm{Fun}(\Delta^2, \mathcal{C})}(\sigma, \tau) \rightarrow \mathrm{Hom}_{\mathrm{Fun}(\Delta^1, \mathcal{C})}(f, g)$ is a trivial Kan fibration.* 04Q2

Proof. By virtue of Proposition 3.3.7.6, it will suffice to show that every fiber of θ is a contractible Kan complex. Let $D : \mathrm{Fun}(\Delta^2, \mathcal{C}) \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C})$ denote the functor given by precomposition with the inclusion map $\Delta^1 \simeq N_\bullet(\{0 < 2\}) \hookrightarrow \Delta^2$, and let $E : \mathrm{Fun}(\Delta^1, \mathcal{C}) \rightarrow \mathcal{C}$ be given by evaluation at the final vertex $1 \in \Delta^1$. Let $\gamma : \Delta^2 \times \Delta^1 \rightarrow \Delta^2$ be the morphism of simplicial sets given on vertices by the formula $\gamma(i, j) = \begin{cases} 1 & \text{if } (i, j) = (0, 2) \\ i & \text{otherwise.} \end{cases}$. Then the composition

$$\Delta^2 \times \Delta^1 \xrightarrow{\gamma} \Delta^2 \xrightarrow{\sigma} \mathcal{C}$$

can be regarded as a morphism $e : \tilde{f} \rightarrow \sigma$ in the ∞ -category $\mathrm{Fun}(\Delta^2, \mathcal{C})$. It follows from Corollary 5.3.7.4 that the morphism e is $(E \circ D)$ -cocartesian and that $D(e)$ is E -cocartesian. Consequently, the morphism e is D -cocartesian (Corollary 5.1.2.6). Using Proposition 5.1.2.1, we deduce that every fiber of θ is homotopy equivalent to a fiber of the restriction map $\theta' : \mathrm{Hom}_{\mathrm{Fun}(\Delta^2, \mathcal{C})}(\tilde{f}, \tau) \rightarrow \mathrm{Hom}_{\mathrm{Fun}(\Delta^1, \mathcal{C})}(f, g)$. It will therefore suffice to prove Corollary 9.5.7.8 in the special case where $\sigma = \tilde{f}$. By a similar argument, we may also assume that τ is the degenerate 2-simplex $\tilde{g} = s_0^1(g)$. In this case, Lemma 9.5.7.7 guarantees that every fiber of θ is homotopy equivalent to the space of solutions to some lifting problem

$$\begin{array}{ccc} A & \xrightarrow{\quad} & X \\ \downarrow f & \nearrow s & \downarrow g \\ B & \xrightarrow{\quad} & Y, \end{array}$$

which is contractible by virtue of our assumption that f is left orthogonal to g . $\square$

Proof of Theorem 9.5.7.2. Let $\mathcal{C}$ be an ∞ -category and let S_L and S_R be collections of morphisms of $\mathcal{C}$. Suppose first that S_L is left orthogonal to S_R . In this case Corollary 9.5.7.8 guarantees that the restriction map

$$\theta : \mathrm{Hom}_{\mathrm{Fun}(\Delta^2, \mathcal{C})}(\sigma, \sigma') \rightarrow \mathrm{Hom}_{\mathrm{Fun}(\Delta^1, \mathcal{C})}(d_1^2(\sigma), d_1^2(\sigma'))$$

is a homotopy equivalence whenever σ belongs to $\mathrm{Fun}_L(\Delta^2, \mathcal{C})$ and σ' belongs to $\mathrm{Fun}_R(\Delta^2, \mathcal{C})$. It follows that the functor

$$D : \mathrm{Fun}_{LR}(\Delta^2, \mathcal{C}) \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C}) \quad \sigma \mapsto d_1^2(\sigma)$$

is fully faithful.

We now prove the converse. Assume that D is fully faithful and that S_L and S_R contain all identity morphisms of $\mathcal{C}$; we wish to show that S_L is left orthogonal to S_R . Suppose we are given a lifting problem τ :

$$\begin{array}{ccc} A & \xrightarrow{\quad} & X \\ \downarrow f & \nearrow s & \downarrow g \\ B & \xrightarrow{\quad} & Y \end{array}$$

in the ∞ -category $\mathcal{C}$, where f belongs to S_L and g belongs to S_R . We wish to show that the solution space $\mathrm{Sol}(\tau)$ is contractible. Let $\tilde{f} = s_1^1(f)$ and $\tilde{g} = s_0^1(g)$ denote the degenerate 2-simplices of $\mathcal{C}$ defined in Notation 9.5.7.3. Since S_L and S_R contain all identity morphisms, we can view $\tilde{f}$ and $\tilde{g}$ as objects of the ∞ -category $\mathrm{Fun}_{LR}(\Delta^2, \mathcal{C})$. Assumption (1) guarantees that the Kan fibration $\mathrm{Hom}_{\mathrm{Fun}(\Delta^2, \mathcal{C})}(\tilde{f}, \tilde{g}) \rightarrow \mathrm{Hom}_{\mathrm{Fun}(\Delta^1, \mathcal{C})}(f, g)$ is a homotopy equivalence. Lemma 9.5.7.7 supplies a homotopy equivalence of $\mathrm{Sol}(\tau)$ with the fiber $\mathrm{Hom}_{\mathrm{Fun}(\Delta^2, \mathcal{C})}(\tilde{f}, \tilde{g})_\tau$, which is contractible by virtue of Proposition 3.3.7.6. $\square$

9.5.8 Factorization Systems

04PC Motivated by Theorem 9.5.7.2, we introduce the following variant of Definition 9.5.5.1:

04PD **Definition 9.5.8.1.** Let $\mathcal{C}$ be an ∞ -category. A *factorization system* on $\mathcal{C}$ is a pair (S_L, S_R) , where S_L and S_R are collections of morphisms of $\mathcal{C}$ which satisfy the following conditions:

(1) For every morphism $f : X \rightarrow Z$ of $\mathcal{C}$, there exists a 2-simplex

$$\begin{array}{ccc} & Y & \\ f_L \nearrow & & \searrow f_R \\ X & \xrightarrow{\quad f \quad} & Z \end{array}$$

where f_L belongs to S_L and f_R belongs to S_R .

(2) Every morphism of S_L is left orthogonal to every morphism of S_R (Definition 9.5.6.4).

(3) The collections S_L and S_R are closed under isomorphism (in the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$).

Remark 9.5.8.2 (Symmetry). Let $\mathcal{C}$ be an ∞ -category and let (S_L, S_R) be a factorization system on $\mathcal{C}$. Then the pair (S_R, S_L) is a weak factorization system on the opposite ∞ -category $\mathcal{C}^{\mathrm{op}}$. 04PE

Example 9.5.8.3 (Trivial Factorization Systems). Let $\mathcal{C}$ be an ∞ -category, let W be the collection of all isomorphisms in $\mathcal{C}$, and let A denote the collection of all morphisms in $\mathcal{C}$. Then the pairs (W, A) and (A, W) are factorization systems on $\mathcal{C}$ (see Corollary 9.5.6.15). 04PF

We now give some more interesting examples of factorization systems. Recall that a functor of ∞ -categories $F : \mathcal{C} \rightarrow \mathcal{D}$ is *categorically n -connective* if it is m -full for every nonnegative integer $m \leq n$ (Definition 4.8.7.1), and *essentially $(n - 1)$ -categorical* if it is m -full for $m > n$ (Definition 4.8.6.1). Let $\mathcal{QC}$ denote the ∞ -category of (small) ∞ -categories (Construction 5.5.4.1).

Proposition 9.5.8.4. *Let n be an integer, let S_L denote the collection of all categorically n -connective functors, and let S_R denote the collection of all essentially $(n - 1)$ -categorical functors. Then the pair (S_L, S_R) is a factorization system on the ∞ -category $\mathcal{QC}$.* 05E7

Proof. We first observe that S_R is closed under the formation of relative diagonals: that is, if a functor $G : \mathcal{C} \rightarrow \mathcal{D}$ is essentially $(n - 1)$ -categorical, then the relative diagonal of G (formed in the ∞ -category $\mathcal{QC}$) has the same property. Using Exercise 7.6.3.13, we can identify the relative diagonal of G with the inclusion map $\iota : \mathcal{C} \hookrightarrow \mathcal{C} \times_{\mathcal{D}}^{\mathrm{h}} \mathcal{C}$. For $n \geq 1$, it follows from Variant 4.8.6.15 that ι is essentially $(n - 2)$ -categorical, and therefore also essentially $(n - 1)$ -categorical (Remark 4.8.6.6). If $n \leq 0$, then the functor G is fully faithful, so ι is an equivalence of ∞ -categories.

It follows from Remarks 4.8.5.16, 4.8.5.17, and 4.8.5.18 that S_L and S_R are invariant under isomorphism. Theorem 4.8.8.3 asserts that every functor $F : \mathcal{C} \rightarrow \mathcal{E}$ admits a factorization $\mathcal{C} \xrightarrow{F_L} \mathcal{D} \xrightarrow{F_R} \mathcal{E}$, where F_L belongs to S_L and F_R belongs to S_R . We will complete the proof by showing that S_L is left orthogonal to S_R . By virtue of (the dual of) Corollary 9.5.6.22, it will suffice to show that S_L is weakly left orthogonal to S_R : that is, every lifting problem

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{\quad} & \mathcal{C} \\ \downarrow F & \nearrow \text{dashed} & \downarrow G \\ \mathcal{B} & \xrightarrow{\quad} & \mathcal{D} \end{array}$$

05E8

(9.29)

in the ∞ -category $\mathcal{QC}$ admits a solution, provided that F is categorically n -connective and G is essentially $(n - 1)$ -categorical. By virtue of Corollary 5.6.5.18, we may assume that

(9.29) arises from a commutative diagram in the category of simplicial sets. Using Corollary 4.5.2.24, we can further assume that F is a monomorphism of simplicial sets and that G is an isofibration. In this case, the lifting problem (9.29) already admits a solution in the category of simplicial sets: see Corollary 4.8.7.18 and Remark 4.8.7.19. $\square$

05E9 Corollary 9.5.8.5. *Let n be an integer, let S_L denote the collection of all n -connective morphisms between Kan complexes, and let S_R denote the collection of all $(n-1)$ -truncated morphisms between Kan complexes. Then the pair (S_L, S_R) determines a factorization system on the ∞ -category $\mathcal{S}$.*

Proof. Recall that a morphism of Kan complexes is n -connective if and only if it is categorically n -connective (Example 4.8.7.3), and $(n-1)$ -truncated if and only if it is essentially $(n-1)$ -categorical (Example 4.8.6.3). It follows immediately from Proposition 9.5.8.4 that S_L and S_R are closed under isomorphism, and that S_L is left orthogonal to S_R . To complete the proof, it suffices to show that every morphism of Kan complexes $f : X \rightarrow Z$ admits a factorization $X \xrightarrow{f_L} Y \xrightarrow{f_R} Z$, where f_L is n -connective and f_R is $(n-1)$ -truncated. This is the content of Corollary 4.8.8.9. $\square$

04QD Proposition 9.5.8.6. *Let $\mathcal{C}$ be an ∞ -category, let (S_L, S_R) be a factorization system on $\mathcal{C}$, and let $\mathrm{Fun}_{LR}(\Delta^2, \mathcal{C}) \subseteq \mathrm{Fun}(\Delta^2, \mathcal{C})$ be the full subcategory of Notation 9.5.7.1. Then the restriction map*

$$D : \mathrm{Fun}_{LR}(\Delta^2, \mathcal{C}) \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C}) \quad \sigma \mapsto d_1^2(\sigma)$$

is a trivial Kan fibration.

Proof. Condition (1) of Definition 9.5.8.1 guarantees that D is surjective on objects, and condition (2) guarantees that D is fully faithful (Theorem 9.5.7.2). Applying the criterion Theorem 4.6.2.21, we deduce that D is an equivalence of ∞ -categories. Condition (3) of Definition 9.5.8.1 guarantees that the full subcategory $\mathrm{Fun}_{LR}(\Delta^2, \mathcal{C}) \subseteq \mathrm{Fun}(\Delta^2, \mathcal{C})$ is replete, so that D is an isofibration of ∞ -categories (see Corollary 4.4.5.3). Applying Proposition 4.5.5.20, we conclude that D is a trivial Kan fibration. $\square$

04QE Corollary 9.5.8.7. *Let $\mathcal{C}$ be an ∞ -category and let (S_L, S_R) be a factorization system on $\mathcal{C}$. Then every isomorphism in $\mathcal{C}$ is contained in both S_L and S_R .*

Proof. Let W be the collection of all isomorphisms in $\mathcal{C}$, and set $S_L^+ = S_L \cup W$ and $S_R^+ = S_R \cup W$. Using Corollary 9.5.6.15, we deduce that S_L^+ is left orthogonal to S_R^+ , so that (S_L^+, S_R^+) is also a factorization system on $\mathcal{C}$. Let $\mathrm{Fun}_{LR}(\Delta^2, \mathcal{C})$ be as in Notation 9.5.7.1 and

define $\mathrm{Fun}_{LR}^+(\Delta^2, \mathcal{C})$ similarly. We then have a commutative diagram

$$\begin{array}{ccc} \mathrm{Fun}_{LR}(\Delta^2, \mathcal{C}) & \xrightarrow{\quad} & \mathrm{Fun}_{LR}^+(\Delta^2, \mathcal{C}) \\ & \searrow D & \swarrow D^+ \\ & \mathrm{Fun}(\Delta^1, \mathcal{C}) & \end{array}$$

where both of the vertical maps are trivial Kan fibrations (Proposition 9.5.8.6). It follows that the inclusion map $\mathrm{Fun}_{LR}(\Delta^2, \mathcal{C}) \hookrightarrow \mathrm{Fun}_{LR}^+(\Delta^2, \mathcal{C})$ is an equivalence of ∞ -categories. Since $\mathrm{Fun}_{LR}(\Delta^2, \mathcal{C})$ is a replete full subcategory of $\mathrm{Fun}_{LR}^+(\Delta^2, \mathcal{C})$, we must have $\mathrm{Fun}_{LR}(\Delta^2, \mathcal{C}) = \mathrm{Fun}_{LR}^+(\Delta^2, \mathcal{C})$. In particular, if $f : X \rightarrow Y$ is an isomorphism in $\mathcal{C}$, then the degenerate 2-simplices $s_0^1(f)$ and $s_1^1(f)$ are both contained in $\mathrm{Fun}_{LR}(\Delta^2, \mathcal{C})$, so that f is contained in both S_L and S_R . $\square$

Corollary 9.5.8.8. *Let $\mathcal{C}$ be an ∞ -category and let (S_L, S_R) be a factorization system on $\mathcal{C}$. Then S_L and S_R are closed under retracts (in the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$).* 04QF

Proof. We will show that S_L is closed under retracts; the analogous statement for S_R follows by a similar argument. By virtue of Proposition 9.5.8.6, the restriction map

$$D : \mathrm{Fun}_{LR}(\Delta^2, \mathcal{C}) \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C}) \quad \sigma \mapsto d_1^2(\sigma)$$

is a trivial Kan fibration. It therefore admits a section $\mathrm{Fun}(\Delta^1, \mathcal{C}) \rightarrow \mathrm{Fun}_{LR}(\Delta^2, \mathcal{C})$, which carries each morphism $f : X \rightarrow Z$ of $\mathcal{C}$ to a 2-simplex $\sigma_f :$

$$\begin{array}{ccc} & Y & \\ f_L \nearrow & & \searrow f_R \\ X & \xrightarrow{f} & Z, \end{array}$$

where $f_L \in S_L$ and $f_R \in S_R$. We will complete the proof by showing that f belongs to S_L if and only if f_R is an isomorphism in $\mathcal{C}$. One direction is clear: if f_R is an isomorphism, then f is isomorphic to f_L in the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$, and therefore belongs to S_L by virtue of our assumption that S_L is closed under isomorphism. For the converse, assume that f belongs to S_L . Since id_Z belongs to S_R (Corollary 9.5.8.7), the degenerate 2-simplex $\tilde{f} = s_1^1(f)$ can be regarded as an object of $\mathrm{Fun}_{LR}(\Delta^2, \mathcal{C})$ satisfying $D(\tilde{f}) = f = D(\sigma_f)$. Since D is an equivalence of ∞ -categories, the 2-simplex σ_f is isomorphic to $\tilde{f}$ as an object of the ∞ -category $\mathrm{Fun}_{LR}(\Delta^2, \mathcal{C})$. It follows that $f_R = d_0^2(\sigma_f)$ is isomorphic to $\mathrm{id}_Z = d_0^2(\tilde{f})$ as an object of the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$, so that f_R is an isomorphism (Example 4.4.1.14). $\square$

04QG **Corollary 9.5.8.9.** *Let $\mathcal{C}$ be an ∞ -category and let (S_L, S_R) be a factorization system on $\mathcal{C}$. Then (S_L, S_R) is a weak factorization system on $\mathcal{C}$.*

Proof. The only nontrivial point is to verify that S_L and S_R are closed under retracts, which follows from Corollary 9.5.8.8. $\square$

Beware that the converse of Corollary 9.5.8.9 is false in general:

04PH **Exercise 9.5.8.10.** Let $\mathbf{Set}$ denote the category of sets and let $\mathcal{C} = \mathbf{N}_\bullet(\mathbf{Set})$ be the associated ∞ -category. Let S be the collection of surjective functions, and let I be the collection of injective functions. Show that:

- The pair (S, I) is a factorization system on $\mathcal{C}$.
- The pair (I, S) is a weak factorization system on $\mathcal{C}$.
- The pair (I, S) is not a factorization system on $\mathcal{C}$.

In the situation of Definition 9.5.8.1, either of the collections S_L and S_R can be recovered from the other.

04PJ **Proposition 9.5.8.11.** *Let $\mathcal{C}$ be an ∞ -category, let (S_L, S_R) be a factorization system on $\mathcal{C}$, and let f be a morphism of $\mathcal{C}$. The following conditions are equivalent:*

- (1) *The morphism f belongs to S_L .*
- (2) *The morphism f is left orthogonal to S_R .*
- (3) *The morphism f is weakly left orthogonal to S_R .*

Proof. The implication $(1) \Rightarrow (2)$ is immediate from the definition, the implication $(2) \Rightarrow (3)$ follows from Remark 9.5.6.7, and the implication $(3) \Rightarrow (1)$ follows from Proposition 9.5.5.5 (together with Corollary 9.5.8.9). $\square$

04PK **Corollary 9.5.8.12.** *Let $\mathcal{C}$ be an ∞ -category which admits pushouts and let (S_L, S_R) be a weak factorization system on $\mathcal{C}$. The following conditions are equivalent:*

- (1) *The pair (S_L, S_R) is a factorization system on $\mathcal{C}$.*
- (2) *For every 2-simplex*

$$\begin{array}{ccc}
 & Y & \\
 f \nearrow & & \searrow g \\
 X & \xrightarrow{h} & Z
 \end{array}$$

of $\mathcal{C}$, if f and h belong to S_L , then g also belongs to S_L .

- (3) For every morphism $f : X \rightarrow Y$ which belongs to S_L , the relative codiagonal $\gamma_{X/Y} : Y \amalg_X Y \rightarrow Y$ also belongs to S_L .

Proof. We first show that (1) $\Rightarrow$ (2). Assume that (S_L, S_R) is a factorization system and consider a 2-simplex

$$\begin{array}{ccc} & Y & \\ f \nearrow & & \searrow g \\ X & \xrightarrow{h} & Z \end{array}$$

of $\mathcal{C}$. If f and h belong to S_L , then they are left orthogonal to S_R . Applying Corollary 9.5.6.16, we deduce that g is also left orthogonal to S_R , so that $g \in S_L$ by virtue of Proposition 9.5.8.11.

We now show that (2) implies (3). Let $f : X \rightarrow Y$ be a morphism which belongs to S_L . Then the relative codiagonal $\gamma_{X/Y}$ fits into a commutative diagram

$$\begin{array}{ccc} & Y \amalg_X Y & \\ f' \nearrow & & \searrow \gamma_{X/Y} \\ Y & \xrightarrow{\text{id}_Y} & Y, \end{array}$$

where f' is a pushout of f . Since S_L is weakly saturated (Corollary 9.5.5.6), it contains the morphisms f' and id_Y . If condition (2) is satisfied, then $\gamma_{X/Y}$ also contains $\gamma_{X/Y}$.

We now complete the proof by showing that (3) implies (1). Let g be a morphism of $\mathcal{C}$ which belongs to S_R . Then g is weakly right orthogonal to S_L , and we wish to show that g is right orthogonal to S_L . This follows by combining assumption (3) with Corollary 9.5.6.22. $\square$

Proposition 9.5.8.13 (Lifting Factorization Systems). *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a cocartesian 04PL fibration of ∞ -categories and let (S_L, S_R) be a weak factorization system on $\mathcal{C}$. Let $\tilde{S}_L$ denote the collection of all U -cocartesian morphisms $\tilde{f}$ in $\mathcal{E}$ satisfying $U(\tilde{f}) \in S_L$, and let $\tilde{S}_R$ be the collection of all morphisms $\tilde{g}$ in $\mathcal{E}$ satisfying $U(\tilde{g}) \in S_R$. Then the pair $(\tilde{S}_L, \tilde{S}_R)$ is a weak factorization system on $\mathcal{E}$. If (S_L, S_R) is a factorization system on $\mathcal{C}$, then $(\tilde{S}_L, \tilde{S}_R)$ is a factorization system on $\mathcal{E}$.*

Proof. By assumption, the collection S_L is weakly left orthogonal to S_R . Applying Corollary 9.5.6.24, we see that $\tilde{S}_L$ is weakly left orthogonal to $\tilde{S}_R$ (and left orthogonal if the pair (S_L, S_R) is a factorization system on $\mathcal{C}$). Since S_L and S_R are closed under isomorphism, the collections $\tilde{S}_L$ and $\tilde{S}_R$ have the same property (see Corollary 8.5.1.13). We will complete

the proof by showing that the pair $(\tilde{S}_L, \tilde{S}_R)$ satisfies condition (1) of Definition 9.5.5.1. Let $\tilde{h} : \tilde{X} \rightarrow \tilde{Z}$ be a morphism in the ∞ -category $\mathcal{E}$, and let $h : X \rightarrow Z$ denote its image in the ∞ -category $\mathcal{C}$. Since (S_L, S_R) is a weak factorization system, we can choose a 2-simplex $\sigma :$

$$\begin{array}{ccc} & Y & \\ f \nearrow & & \searrow g \\ X & \xrightarrow{h} & Z \end{array}$$

of $\mathcal{C}$, where f belongs to S_L and g belongs to S_R . Our assumption that U is a cocartesian fibration guarantees that we can lift f to a U -cocartesian morphism $\tilde{f} : \tilde{X} \rightarrow \tilde{Y}$ in the ∞ -category $\mathcal{E}$. Since $\tilde{f}$ is U -cocartesian, we can lift σ to a 2-simplex $\tilde{\sigma} :$

$$\begin{array}{ccc} & \tilde{Y} & \\ \tilde{f} \nearrow & & \searrow \tilde{g} \\ \tilde{X} & \xrightarrow{\tilde{h}} & \tilde{Z} \end{array}$$

in the ∞ -category $\mathcal{E}$. By construction, we have $\tilde{f} \in \tilde{S}_L$ and $\tilde{g} \in \tilde{S}_R$. □

04PM Corollary 9.5.8.14. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a cocartesian fibration of ∞ -categories, let S be the collection of all U -cocartesian morphisms of $\mathcal{E}$, and let T be the collection of all morphisms f of $\mathcal{E}$ such that $U(f)$ is an isomorphism in $\mathcal{C}$. Then the pair (S, T) is a factorization system on $\mathcal{E}$.*

Proof. Combine Proposition 9.5.8.13 with Example 9.5.8.3. □

One can produce many examples of factorization systems using the small object argument of §9.5.3.

04PM Theorem 9.5.8.15 (Existence of Factorization Systems). *Let $\mathcal{C}$ be an ∞ -category and let W be a collection of morphisms of $\mathcal{C}$. Assume that:*

- (1) *The ∞ -category $\mathcal{C}$ is locally small and admits small colimits.*
- (2) *The collection W is small.*
- (3) *For every morphism $w : X \rightarrow Y$ in W , the objects X and Y are κ -compact for some small cardinal κ .*

Then $\mathcal{C}$ admits a factorization system (S_L, S_R) , where S_R is the collection of morphisms of $\mathcal{C}$ which are right orthogonal to W .

Proof. By virtue of Corollary 9.5.6.22 (and Proposition [?]), we can enlarge W to arrange that every morphism $w : A \rightarrow B$ which belongs to W admits a relative codiagonal $\gamma_{A/B} : B \amalg_A B \rightarrow B$ which also belongs to W . Applying Theorem 9.5.5.7, we conclude that $\mathcal{C}$ admits a weak factorization system (S_L, S_R) , where S_L is the weakly saturated class of morphisms generated by W and S_R is the collection of morphisms which are weakly right orthogonal to W . Using Corollary 9.5.6.22, we see that a morphism $g : X \rightarrow Y$ of $\mathcal{C}$ belongs to S_R if and only if it is right orthogonal to W . If this condition is satisfied, then Corollary 9.5.6.21 guarantees that g is right orthogonal to W . Allowing g to vary, we conclude that (S_L, S_R) is a factorization system. $\square$

Remark 9.5.8.16. In the situation of Theorem 9.5.8.15, the collection S_L is characterized 04PP by the fact that it is the smallest weakly saturated collection of morphisms which contains W and also satisfies the equivalent conditions of Corollary 9.5.8.12. Beware that it is generally larger than the weakly saturated collection of morphisms generated by W .

We close this section by recording a converse to Proposition 9.5.8.6:

Theorem 9.5.8.17. Let $\mathcal{C}$ be an ∞ -category, let S_L and S_R be collections of morphisms 04PT of $\mathcal{C}$, and let $\text{Fun}_{LR}(\Delta^2, \mathcal{C}) \subseteq \text{Fun}(\Delta^2, \mathcal{C})$ be the full subcategory of Notation 9.5.7.1. Then (S_L, S_R) is a factorization system on $\mathcal{C}$ if and only if it satisfies the following conditions:

(1) The restriction map

$$D : \text{Fun}_{LR}(\Delta^2, \mathcal{C}) \rightarrow \text{Fun}(\Delta^1, \mathcal{C}) \quad \sigma \mapsto d_1^2(\sigma)$$

is an equivalence of ∞ -categories.

(2) Every identity morphism of $\mathcal{C}$ is contained in both S_L and S_R .

(3) The collections S_L and S_R are closed under isomorphism (in the ∞ -category $\text{Fun}(\Delta^1, \mathcal{C})$).

Proof. The necessity of (3) is immediate from the definitions, and the necessity of (1) and (2) follow from Proposition 9.5.8.6 and Corollary 9.5.8.7, respectively. For the converse, assume that conditions (1), (2), and (3) are satisfied. Combining (1) and (3) with Theorem 9.5.7.2, we deduce that S_L is left orthogonal to S_R . We are therefore reduced to proving that the functor D is surjective on objects. Assumption (3) guarantees that the full subcategory $\text{Fun}_{LR}(\Delta^2, \mathcal{C}) \subseteq \text{Fun}(\Delta^2, \mathcal{C})$ is replete, so that D is an isofibration (see Corollary 4.4.5.3). It will therefore suffice to show that D is essentially surjective, which follows from assumption (1). $\square$

04PV **Corollary 9.5.8.18** (Exponentiation of Factorization Systems). *Let $\mathcal{C}$ be an ∞ -category equipped with a factorization system (S_L, S_R) and let K be a simplicial set. Then the ∞ -category $\mathrm{Fun}(K, \mathcal{C})$ admits a factorization system (S_L^K, S_R^K) , where S_L^K denotes the collection of all morphisms f in $\mathrm{Fun}(K, \mathcal{C})$ such that $f(v) \in S_L$ for each vertex v of K , and S_R^K is defined similarly.*

Proof. Since S_L and S_R contain identity morphisms and are closed under isomorphism, the collections S_L^K and S_R^K have the same properties. By virtue of Theorem 9.5.8.17, it will suffice to show that the restriction map

$$D_K : \mathrm{Fun}_{LR}(\Delta^2, \mathrm{Fun}(K, \mathcal{C})) \rightarrow \mathrm{Fun}(\Delta^1, \mathrm{Fun}(K, \mathcal{C})) \quad \sigma \mapsto d_1^2(\sigma)$$

is an equivalence of ∞ -categories. This follows from Remark 4.5.1.16, since D_K is obtained by applying the functor $\mathrm{Fun}(K, \bullet)$ to the restriction map $D : \mathrm{Fun}_{LR}(\Delta^2, \mathcal{C}) \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C})$. $\square$

9.6 Truncated Objects of ∞ -Categories

05EA 9.6.1 Truncated Objects

05EB Let n be an integer. Recall that a Kan complex X is *n-truncated* if, for every integer $m \geq n + 2$, every morphism $\partial\Delta^m \rightarrow X$ can be extended to an m -simplex of X . We now introduce a counterpart of this condition for objects of an arbitrary ∞ -category.

05EC **Definition 9.6.1.1.** Let $\mathcal{C}$ be an ∞ -category and let n be an integer. We say that an object $X \in \mathcal{C}$ is *n-truncated* if, for every object $Y \in \mathcal{C}$, the morphism space $\mathrm{Hom}_{\mathcal{C}}(Y, X)$ is an n -truncated Kan complex.

05ED **Remark 9.6.1.2.** In the formulation of Definition 9.6.1.1, we can replace $M = \mathrm{Hom}_{\mathcal{C}}(Y, X)$ by any Kan complex which is homotopy equivalent to M . For example, we can replace M by the pinched morphism spaces $\mathrm{Hom}_{\mathcal{C}}^L(Y, X)$ and $\mathrm{Hom}_{\mathcal{C}}^R(Y, X)$ (see Proposition 4.6.5.10).

05EE **Example 9.6.1.3.** Let $\mathcal{C}$ be an ∞ -category. For $n \leq -2$, an object $X \in \mathcal{C}$ is n -truncated if and only if it is a final object of $\mathcal{C}$ (Definition 4.6.7.1). In particular, this condition is independent of n , so long as $n \leq -2$. Consequently, in the setting of Definition 9.6.1.1, there is no loss of generality in assuming that $n \geq -2$.

05EF **Example 9.6.1.4.** Let X be a Kan complex and let n be an integer. The following conditions are equivalent:

- (1) The Kan complex X is n -truncated, in the sense of Definition 3.5.7.1.
- (2) For every Kan complex Y , the Kan complex $\mathrm{Fun}(Y, X)$ is n -truncated.

- (3) For every simplicial set Y , the Kan complex $\mathrm{Fun}(Y, X)$ is n -truncated.
- (4) The Kan complex X is n -truncated when regarded as an object of the ∞ -category $\mathcal{S}$ (in the sense of Definition 9.6.1.1).

The implications (3) $\Rightarrow$ (2) $\Rightarrow$ (1) are immediate, the implication (1) $\Rightarrow$ (3) follows from Corollary 3.5.9.28, and the equivalence (2) $\Leftrightarrow$ (4) follows from the homotopy equivalence $\mathrm{Fun}(Y, X) \rightarrow \mathrm{Hom}_{\mathcal{S}}(Y, X)$ of Remark 5.5.1.5.

Remark 9.6.1.5. Let $\mathcal{C}$ be an ∞ -category, and let X and Y be objects of $\mathcal{C}$. If X is n -truncated and Y is a retract of X , then Y is also n -truncated. In particular, if X and Y are isomorphic, then X is n -truncated if and only if Y is n -truncated. 05EG

Remark 9.6.1.6. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, let n be an integer, and let $X \in \mathcal{C}$ be an object whose image $F(X)$ is an n -truncated object of $\mathcal{D}$. If the functor F is essentially $(n+1)$ -categorical (Definition 4.8.6.1), then X is an n -truncated object of $\mathcal{C}$ (see Proposition 3.5.9.13). In particular, if F is fully faithful, then X is an n -truncated object of $\mathcal{C}$. 05EH

Remark 9.6.1.7. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be an equivalence of ∞ -categories. Then an object $X \in \mathcal{C}$ is n -truncated if and only if the image $Y = F(X)$ is an n -truncated object of $\mathcal{D}$. The “if” direction follows from Remark 9.6.1.6. For the converse, suppose that X is n -truncated and let $G : \mathcal{D} \rightarrow \mathcal{C}$ be a homotopy inverse to F . Then $G(Y) \in \mathcal{C}$ is isomorphic to X , and is therefore an n -truncated object of $\mathcal{C}$ (Remark 9.6.1.5). Since G is fully faithful, Remark 9.6.1.6 guarantees that Y is an n -truncated object of $\mathcal{D}$. 05EJ

Remark 9.6.1.8. Let $\mathcal{C}$ be an ∞ -category and let n be an integer. Then $\mathcal{C}$ is locally n -truncated (in the sense of Definition 4.8.2.1) if and only if every object $X \in \mathcal{C}$ is n -truncated (in the sense of Definition 9.6.1.1). 05EK

Remark 9.6.1.9 (Monotonicity). Let $\mathcal{C}$ be an ∞ -category and let $m \leq n$ be integer. If an object $X \in \mathcal{C}$ is m -truncated, then it is also n -truncated (see Remark 3.5.9.6). 05EL

Remark 9.6.1.10. Let $\mathcal{C}$ be an ∞ -category, let X be an object of $\mathcal{C}$, and let $n \geq -2$ be an integer. The following conditions are equivalent: 05EM

- (1) The object $X \in \mathcal{C}$ is n -truncated, in the sense of Definition 9.6.1.1.
- (2) The constant map $\partial\Delta^{n+2} \rightarrow \{\mathrm{id}_X\} \hookrightarrow \mathrm{Hom}_{\mathcal{C}}(X, X)$ exhibits X as a power of itself by $\partial\Delta^{n+2}$, in the sense of Definition 7.1.2.1.

- (3) The constant map

$$(\partial\Delta^{n+2})^{\triangleright} \simeq \Lambda_{n+3}^{n+3} \rightarrow \{X\} \hookrightarrow \mathcal{C}$$

is a limit diagram in $\mathcal{C}$, in the sense of Definition 7.1.3.4.

The equivalence (1) $\Leftrightarrow$ (2) follows from Corollary 3.5.9.22, and the equivalence (2) $\Leftrightarrow$ (3) from Remark 7.1.2.6.

05EN **Remark 9.6.1.11.** In the formulation of Remark 9.6.1.10, we can replace $\partial\Delta^{n+2}$ by any simplicial set K of the same weak homotopy type (that is, any simplicial set K for which the geometric realization $|K|$ is homotopy equivalent to a sphere of dimension $n+1$). For example, we can take K to be the subdivision $\text{Sd}(\Delta^{n+1})$ (see Proposition 3.3.4.8).

05EP **Remark 9.6.1.12.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories which preserves finite limits. Then, for every n -truncated object $X \in \mathcal{C}$, the image $F(X)$ is an n -truncated object of $\mathcal{D}$. This follows from the criterion of Remark 9.6.1.10.

05EQ **Remark 9.6.1.13.** Let $\mathcal{C}$ be an ∞ -category and let n be an integer. Then an object $X \in \mathcal{C}$ is n -truncated if and only if the right fibration $\mathcal{C}_{/X} \rightarrow \mathcal{C}$ is essentially n -categorical. This follows from the criterion of Corollary 5.1.5.18 (together with Remark 9.6.1.2).

05K2 **Proposition 9.6.1.14.** Let $\mathcal{C}$ be an ∞ -category and let n be an integer. Let X be an object of $\mathcal{C}$, and let us abuse notation by identifying X with its image in the homotopy n -category $\text{h}_{\leq n}(\mathcal{C})$ (Notation 4.8.4.2). Then X is $(n-1)$ -truncated if and only if the diagram of ∞ -categories

$$\begin{array}{ccc} \mathcal{C}_{/X} & \longrightarrow & \text{h}_{\leq n}(\mathcal{C})_{/X} \\ \downarrow & & \downarrow \\ \mathcal{C} & \longrightarrow & \text{h}_{\leq n}(\mathcal{C}) \end{array} \quad (9.30)$$

is a categorical pullback square.

Proof. Since the vertical maps in the diagram (9.30) are right fibrations (Proposition 4.3.6.1), it is a categorical pullback square if and only if, for every object $Y \in \mathcal{C}$, the induced map of right-pinched morphism spaces

$$\theta : \text{Hom}_{\mathcal{C}}^{\text{R}}(Y, X) = \{Y\} \times_{\mathcal{C}} \mathcal{C}_{/Y} \rightarrow \{Y\} \times_{\text{h}_{\leq n}(\mathcal{C})} (\text{h}_{\leq n}(\mathcal{C}))_{/X} = \text{Hom}_{\text{h}_{\leq n}(\mathcal{C})}^{\text{R}}(Y, X)$$

is a homotopy equivalence (Corollary 5.1.6.4). It follows from Corollary 4.8.4.8 that θ exhibits $\text{Hom}_{\text{h}_{\leq n}(\mathcal{C})}^{\text{R}}(Y, X)$ as an $(n-1)$ -truncation of $\text{Hom}_{\mathcal{C}}^{\text{R}}(Y, X)$. In particular, it is a homotopy equivalence if and only if $\text{Hom}_{\mathcal{C}}^{\text{R}}(Y, X)$ is $(n-1)$ -truncated. This condition is satisfied for every object $Y \in \mathcal{C}$ if and only if the object X is $(n-1)$ -truncated (Remark 9.6.1.2). $\square$

05K4 **Corollary 9.6.1.15.** Let $\mathcal{C}$ be an ∞ -category, let n be an integer, and let X be an $(n-1)$ -truncated object of $\mathcal{C}$. Then the canonical map $\text{h}_{\leq n}(\mathcal{C}_{/X}) \rightarrow \text{h}_{\leq n}(\mathcal{C})_{/X}$ is an equivalence of ∞ -categories.

Proof. Combine Propositions 9.6.1.14 and 4.8.4.20. $\square$

Proposition 9.6.1.16 (Limits of Truncated Objects). *Let $\mathcal{C}$ be an ∞ -category and let n be an integer. Then the collection of n -truncated objects of $\mathcal{C}$ is closed under limits. That is, if $F : A^\triangleleft \rightarrow \mathcal{C}$ is a limit diagram in $\mathcal{C}$ having the property that $F(a)$ is n -truncated for each vertex $a \in A$, then F carries the cone point of $A^\triangleleft$ to an n -truncated object of $\mathcal{C}$.* 05ER

Proof. Fix an object $C \in \mathcal{C}$ and let $h^C : \mathcal{C} \rightarrow \mathcal{S}$ denote the functor corepresented by C . We wish to show that the composition

$$A^\triangleleft \xrightarrow{F} \mathcal{C} \xrightarrow{h^C} \mathcal{S}$$

carries the cone point of $A^\triangleleft$ to an n -truncated Kan complex. This follows from Remark 7.4.1.5, since $h^C \circ F$ is a limit diagram in the ∞ -category $\mathcal{S}$ (Corollary 7.4.1.19). $\square$

Remark 9.6.1.17. Let $\mathcal{C}$ be an ∞ -category, let X be an object of $\mathcal{C}$, and let $\mathcal{C}' \subseteq \mathcal{C}$ be the full subcategory of $\mathcal{C}$ spanned by those objects $Y \in \mathcal{C}$ for which the morphism space $\mathrm{Hom}_{\mathcal{C}}(Y, X)$ is n -truncated. Since the representable functor 05ES

$$h_X : \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{S} \quad Y \mapsto \mathrm{Hom}_{\mathcal{C}}(Y, X)$$

carries colimits in the ∞ -category $\mathcal{C}$ to limits in the ∞ -category of spaces $\mathcal{S}$, (Corollary 7.4.1.19), Remark 7.4.1.5 guarantees that the subcategory $\mathcal{C}' \subseteq \mathcal{C}$ is closed under the formation of colimits. Consequently, if $\mathcal{C}$ is generated (under the formation of small colimits) by some full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$, then the object X is n -truncated if and only if the morphism space $\mathrm{Hom}_{\mathcal{C}}(Y, X)$ is n -truncated for each object $Y \in \mathcal{C}_0$.

Definition 9.6.1.1 can be reformulated as a filling condition:

Proposition 9.6.1.18. *Let $\mathcal{C}$ be an ∞ -category, let X be an object of $\mathcal{C}$, and let $n \geq -2$ be an integer. Then X is n -truncated if and only if it satisfies the following condition for each $m \geq n + 3$:* 05ET

($*_m$) *Every morphism $\sigma : \partial\Delta^m \rightarrow \mathcal{C}$ satisfying $\sigma(m) = X$ can be extended to an m -simplex of $\mathcal{C}$.*

Proof. This is a special case of Proposition 4.8.6.20, since the object X is n -truncated if and only if the right fibration $\mathcal{C}_{/X} \rightarrow \mathcal{C}$ is essentially $(n + 1)$ -categorical (Remark 9.6.1.13). $\square$

The following is a variant of Proposition 4.3.7.12:

Proposition 9.6.1.19. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ and $F : K \rightarrow \mathcal{E}$ be morphisms of simplicial sets, where U is a right fibration. Let n and k be integers such that K is $(k - 1)$ -connective and each fiber of U is n -truncated. Then the induced map $U_{/F} : \mathcal{E}_{/F} \rightarrow \mathcal{C}_{/(U \circ F)}$ is a right fibration, and each fiber of $U_{/F}$ is $(n - k)$ -truncated.* 05Y9

Proof. The first assertion follows from Variant 4.3.6.11. To prove the second, we can use Remark 5.6.7.4 to reduce to the case where $\mathcal{E}$ and $\mathcal{C}$ are ∞ -categories. By virtue of Theorem 4.6.4.19, it will suffice to show that each fiber of the right fibration

$$V : \mathcal{E} \tilde{\times}_{\mathrm{Fun}(K, \mathcal{E})} \{F\} \rightarrow \mathcal{C} \tilde{\times}_{\mathrm{Fun}(K, \mathcal{C})} \{U \circ F\}$$

is $(n - k)$ -truncated. Fix an object $C \in \mathcal{C}$, and set $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$, so that V restricts to a right fibration

$$V_C : \mathcal{E}_C \tilde{\times}_{\mathrm{Fun}(K, \mathcal{E})} \{F\} \rightarrow \{C\} \tilde{\times}_{\mathrm{Fun}(K, \mathcal{C})} \{U \circ F\}.$$

The target of V_C is the Kan complex $\mathrm{Hom}_{\mathrm{Fun}(K, \mathcal{C})}(\underline{C}, U \circ F)$, where $\underline{C}$ denotes the constant functor $K \rightarrow \mathcal{C}$ taking the value C . It follows that V_C is a Kan fibration between Kan complexes (Corollary 4.4.3.8). We will complete the proof by showing that the Kan fibration V_C is $(n - k)$ -truncated.

Note that the morphism V_C factors as a composition

$$\mathcal{E}_C \tilde{\times}_{\mathrm{Fun}(K, \mathcal{E})} \{F\} \xrightarrow{\iota} \mathrm{Fun}(K, \mathcal{E}_C) \tilde{\times}_{\mathrm{Fun}(K, \mathcal{C})} \{F\} \xrightarrow{G} \{C\} \tilde{\times}_{\mathrm{Fun}(K, \mathcal{C})} \{U \circ F\},$$

where G is a pullback of the map

$$\mathrm{Fun}(\Delta^1 \times K, \mathcal{E}) \rightarrow \mathrm{Fun}(\Delta^1 \times K, \mathcal{C}) \times_{\mathrm{Fun}(\{1\} \times K, \mathcal{C})} \mathrm{Fun}(\{1\} \times K, \mathcal{E})$$

and therefore a trivial Kan fibration (see Proposition 4.2.6.1). It will therefore suffice to show that the inclusion map ι is $(n - m + 2)$ -connective. By construction, ι fits into a pullback diagram

$$\begin{array}{ccc} \mathcal{E}_C \tilde{\times}_{\mathrm{Fun}(K, \mathcal{E})} \{F\} & \xrightarrow{\iota} & \mathrm{Fun}(K, \mathcal{E}_C) \tilde{\times}_{\mathrm{Fun}(K, \mathcal{C})} \{F\} \\ \downarrow & & \downarrow \\ \mathcal{E}_C & \xrightarrow{\iota_0} & \mathrm{Fun}(K, \mathcal{E}_C). \end{array}$$

The vertical maps in this diagram are right fibrations between Kan complexes, and therefore Kan fibrations (Corollary 4.4.3.8). It follows that the diagram is a homotopy pullback square (Example 3.4.1.3). We are therefore reduced to proving that ι_0 is $(n - k)$ -truncated (Corollary 3.5.9.11), which is a special case of Corollary 3.5.9.26. $\square$

05YA Corollary 9.6.1.20. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ and $F : K \rightarrow \mathcal{E}$ be morphisms of simplicial sets and let n be an integer. Assume that U is a right fibration with n -truncated fibers and that K is $(n + 1)$ -connective. Then the map $U_{/F} : \mathcal{E}_{/F} \rightarrow \mathcal{C}_{/\overline{F}}$ is a trivial Kan fibration.*

Proof. Combine Propositions 9.6.1.19 and 4.4.2.14. $\square$

Corollary 9.6.1.21. *Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a right fibration of ∞ -categories, let n be an integer 05YB such that every fiber of U is n -truncated, and let K be an $(n+1)$ -connective simplicial set. Then a morphism $\overline{F} : K^\Delta \rightarrow \mathcal{E}$ is a limit diagram in $\mathcal{E}$ if and only if $U \circ \overline{F}$ is a limit diagram in $\mathcal{C}$. In particular, the functor U preserves K -indexed limits.*

Corollary 9.6.1.22. *Let $\mathcal{C}$ be an ∞ -category and let X be an object of $\mathcal{C}$ which is n -truncated 05YC for some integer n . If K is an $(n+1)$ -connective simplicial set, then a morphism $K^\Delta \rightarrow \mathcal{C}_{/X}$ is a limit diagram if and only if its image in $\mathcal{C}$ is a limit diagram. In particular, the forgetful functor $\mathcal{C}_{/X} \rightarrow \mathcal{C}$ preserves K -indexed limits.*

We close this section by classifying the truncated objects of the ∞ -category $\mathcal{QC}$ of (small) ∞ -categories (Construction 5.5.4.1).

Proposition 9.6.1.23. *Let $\mathcal{C}$ be an ∞ -category and let n be an integer. The following 05EU conditions are equivalent:*

- (1) *The ∞ -category $\mathcal{C}$ is n -truncated when viewed as an object of $\mathcal{QC}$, in the sense of Definition 9.6.1.1.*
- (2) *The Kan complex $\mathrm{Fun}(\Delta^1, \mathcal{C})^\simeq$ is n -truncated.*
- (3) *The core $\mathcal{C}^\simeq$ is an n -truncated Kan complex. Moreover, for every pair of objects $X, Y \in \mathcal{C}$, the morphism space $\mathrm{Hom}_{\mathcal{C}}(X, Y)$ is also an n -truncated Kan complex.*

Proof. By virtue of Proposition [?], the ∞ -category $\mathcal{QC}$ is generated under colimits by the object $\Delta^1 \in \mathcal{QC}$. The equivalence (1) $\Leftrightarrow$ (2) now follows by combining Remarks 9.6.1.17 and 5.5.4.5. We next show that, if condition (2) is satisfied, then the core $\mathcal{C}^\simeq$ is an n -truncated Kan complex. Let $\mathrm{Isom}(\mathcal{C})$ denote the full subcategory of $\mathrm{Fun}(\Delta^1, \mathcal{C})$ spanned by the isomorphisms of $\mathcal{C}$. Then the diagonal map

$$\mathcal{C} \hookrightarrow \mathrm{Isom}(\mathcal{C}) \quad X \mapsto \mathrm{id}_X$$

is an equivalence of ∞ -categories (Corollary 4.5.3.13), and therefore restricts to a homotopy equivalence of Kan complexes $\mathcal{C}^\simeq \hookrightarrow \mathrm{Isom}(\mathcal{C})^\simeq$. We are therefore reduced to showing that the Kan complex $\mathrm{Isom}(\mathcal{C})^\simeq$ is n -truncated. Since $\mathrm{Isom}(\mathcal{C})^\simeq$ is a summand of the Kan complex $\mathrm{Fun}(\Delta^1, \mathcal{C})^\simeq$, this follows immediately from assumption (2) if $n \geq -1$. The case $n \leq -2$ then follows from the additional observation that if $\mathrm{Fun}(\Delta^1, \mathcal{C})^\simeq$ is nonempty, then the ∞ -category $\mathcal{C}$ is nonempty, so $\mathrm{Isom}(\mathcal{C})^\simeq$ is nonempty.

We now complete the proof by showing that (2) and (3) are equivalent. By virtue of the preceding argument, we may assume that the core $\mathcal{C}^\simeq$ is n -truncated, so the product $\mathcal{C}^\simeq \times \mathcal{C}^\simeq$ is n -truncated (Remark 3.5.7.6). Using Proposition 3.5.9.13, we see that condition (2) is satisfied if and only if the map of Kan complexes

$$U : \mathrm{Fun}(\Delta^1, \mathcal{C})^\simeq \rightarrow \mathcal{C}^\simeq \times \mathcal{C}^\simeq \quad (f : X \rightarrow Y) \mapsto (X, Y)$$

is n -truncated. Since U is a Kan fibration (Corollary 4.4.5.4), this is equivalent to the requirement that each fiber of U is an n -truncated Kan complex (Proposition 3.5.9.8), which is a restatement of (3). $\square$

05EV **Remark 9.6.1.24.** If $n \geq -1$, we can reformulate condition (3) of Proposition 9.6.1.23 as follows:

(3') For every pair of objects $X, Y \in \mathcal{C}$, the morphism space $\mathrm{Hom}_{\mathcal{C}}(X, Y)$ is n -truncated. Moreover, the summand $\mathrm{Isom}_{\mathcal{C}}(X, Y) \subseteq \mathrm{Hom}_{\mathcal{C}}(X, Y)$ spanned by the isomorphisms from X to Y is $(n - 1)$ -truncated.

See Example 3.5.9.18.

05EW **Corollary 9.6.1.25.** Let $\mathcal{C}$ be an ∞ -category and let n be an integer. Then:

- If $\mathcal{C}$ is an n -truncated object of $\mathcal{QC}$ (in the sense of Definition 9.6.1.1), then it is locally n -truncated (in the sense of Definition 4.8.2.1).
- If $n \geq -1$ and $\mathcal{C}$ is locally $(n - 1)$ -truncated, then it is an n -truncated object of $\mathcal{QC}$.

05EX **Warning 9.6.1.26.** In general, neither implication of Corollary 9.6.1.25 is reversible. See Example 9.6.2.11.

9.6.2 Example: Discrete and Subterminal Objects

04UX We now consider some important special cases of Definition 9.6.1.1.

05EY **Definition 9.6.2.1.** Let $\mathcal{C}$ be an ∞ -category. We will say that an object $X \in \mathcal{C}$ is *discrete* if, for every object $C \in \mathcal{C}$, every connected component of the morphism space $\mathrm{Hom}_{\mathcal{C}}(C, X)$ is contractible.

04UY **Definition 9.6.2.2.** Let $\mathcal{C}$ be an ∞ -category. We will say that an object $X \in \mathcal{C}$ is *subterminal* if, for every object $C \in \mathcal{C}$, the morphism space $\mathrm{Hom}_{\mathcal{C}}(C, X)$ is either empty or contractible.

05EZ **Remark 9.6.2.3.** Let $\mathcal{C}$ be an ∞ -category. Then:

- An object $X \in \mathcal{C}$ is discrete (in the sense of Definition 9.6.2.1) if and only if it is 0-truncated (in the sense of Definition 9.6.2.1).
- An object $X \in \mathcal{C}$ is subterminal (in the sense of Definition 9.6.2.2) if and only if it is (-1) -truncated.

See Examples 3.5.7.4 and 3.5.7.5.

04V0 **Example 9.6.2.4.** Let $\mathcal{C}$ be an ∞ -category. Then every final object of $\mathcal{C}$ is subterminal, and every subterminal object of $\mathcal{C}$ is discrete.

Example 9.6.2.5. Let X be a Kan complex, which we regard as an object of the ∞ -category $\mathcal{S}$ of spaces (Construction 5.5.1.1). Then: 04V1

- The Kan complex X is a discrete object of the ∞ -category $\mathcal{S}$ (in the sense of Definition 9.6.2.1) if and only if every connected component of X is contractible: that is, the projection map $X \rightarrow \pi_0(X)$ is a homotopy equivalence.
- The Kan complex X is a subterminal object of the ∞ -category $\mathcal{S}$ (in the sense of Definition 9.6.2.2) if and only if X is either empty or contractible.

See Example 9.6.1.4.

Example 9.6.2.6. Let $\mathcal{C} = N_\bullet(\mathcal{C}_0)$ be the nerve of an ordinary category $\mathcal{C}_0$. Then: 05F0

- Every object of $\mathcal{C}$ is discrete.
- An object $X \in \mathcal{C}$ is subterminal (in the sense of Definition 9.6.2.2) if and only if it is subterminal in the sense of classical category theory: that is, for every object $Y \in \mathcal{C}$, there is at most one morphism from Y to X .

Remark 9.6.2.7. Let $\mathcal{C}$ be an ∞ -category and let X be an object of $\mathcal{C}$. If X is discrete, 05K5 then the canonical map $h(\mathcal{C}/_X) \rightarrow (h\mathcal{C})/_X$ is an equivalence of categories. This is a special case of Corollary 9.6.1.15.

Proposition 9.6.2.8. Let $\mathcal{C}$ be an ∞ -category and let 05K6

$$\begin{array}{ccc} X_{01} & \longrightarrow & X_0 \\ \downarrow & & \downarrow \\ X_1 & \longrightarrow & X \end{array} \quad (9.31) \quad 05K7$$

be a pullback diagram in $\mathcal{C}$. If the object X is discrete, then (9.31) determines a pullback diagram in the homotopy category $h\mathcal{C}$.

Beware that the conclusion of Proposition 9.6.2.8 is generally false if we do not assume that the object X is discrete (see Warning 7.6.2.3).

Proof of Proposition 9.6.2.8. By virtue of Proposition 7.6.2.14, it will suffice to show that the tautological map $F : \mathcal{C}/_X \rightarrow N_\bullet(h\mathcal{C})/_X$ preserves products. Since X is discrete, we can use Remark 9.6.2.7 to identify F with the canonical map from $\mathcal{C}/_X$ to (the nerve of) its homotopy category, which always preserves products (see Warning 7.6.1.12). $\square$

We now record a partial converse to Example 9.6.2.6.

05F1 **Definition 9.6.2.9.** Let $\mathcal{C}$ be an ∞ -category. We say that $\mathcal{C}$ is *locally discrete* if every object $X \in \mathcal{C}$ is discrete.

Note that an ∞ -category $\mathcal{C}$ is locally discrete if and only if it is locally 0-truncated, in the sense of Definition 4.8.2.1. Invoking Corollary 4.8.2.16, we obtain the following:

05F2 **Remark 9.6.2.10.** Let $\mathcal{C}$ be an ∞ -category. The following conditions are equivalent:

- The ∞ -category $\mathcal{C}$ is locally discrete.
- The comparison map $\mathcal{C} \rightarrow \mathbf{N}_\bullet(\mathbf{h}\mathcal{C})$ is a trivial Kan fibration.
- There exists an ordinary category $\mathcal{C}_0$ and an equivalence of ∞ -categories $\mathcal{C} \rightarrow \mathbf{N}_\bullet(\mathcal{C}_0)$.

05F3 **Example 9.6.2.11.** Let $\mathcal{QC}$ be the ∞ -category of (small) ∞ -categories (Construction 5.5.4.1). Then an object $\mathcal{C} \in \mathcal{QC}$ is discrete (in the sense of Definition 9.6.2.1) if and only if it satisfies the following pair of conditions:

- The ∞ -category $\mathcal{C}$ is locally discrete: that is, there exists an equivalence $\mathcal{C} \rightarrow \mathbf{N}_\bullet(\mathcal{C}_0)$, where $\mathcal{C}_0$ is an ordinary category (Remark 9.6.2.10).
- For every object $X \in \mathcal{C}_0$, the automorphism group $\mathrm{Aut}(X)$ is trivial.

See Proposition 9.6.1.23. Beware that the second condition cannot be omitted.

04V2 **Remark 9.6.2.12.** Let $\mathcal{C}$ be an ∞ -category, let $X \in \mathcal{C}$ be an object, and let $Y \in \mathcal{C}$ be a retract of X . If X is discrete, then Y is also discrete. If X is subterminal, then Y is also subterminal. See Remark 9.6.1.5.

04V3 **Remark 9.6.2.13.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a fully faithful functor of ∞ -categories, and let X be an object of $\mathcal{C}$. Then:

- If $F(X)$ is a discrete object of $\mathcal{D}$, then X is a discrete object of $\mathcal{C}$.
- If $F(X)$ is a subterminal object of $\mathcal{D}$, then X is a subterminal object of $\mathcal{C}$.

In both cases, the converse holds if F is an equivalence of ∞ -categories.

04V4 **Remark 9.6.2.14.** Let $\mathcal{C}$ be an ∞ -category. Then an object $X \in \mathcal{C}$ is discrete if and only if it satisfies the following condition for every integer $m \geq 3$:

- ($\ast_m$) Every morphism $\sigma : \partial\Delta^m \rightarrow \mathcal{C}$ satisfying $\sigma(m) = X$ can be extended to an m -simplex of $\mathcal{C}$.

In this case, X is subterminal if and only if it also satisfies condition ($\ast_2$). See Proposition 9.6.1.18.

Remark 9.6.2.15. Let $\mathcal{C}$ be an ∞ -category and let X be a discrete object of $\mathcal{C}$, and suppose 05YD
we are given a diagram $F : K^\triangleleft \rightarrow \mathcal{C}_{/X}$. If the simplicial set K is connected, then F is a
limit diagram if and only if its image in $\mathcal{C}$ is a limit diagram. In particular, the forgetful
functor $\mathcal{C}_{/X} \rightarrow \mathcal{C}$ preserves K -indexed colimits. If the object X is subterminal, then these
conclusions hold more generally if when the simplicial set. See Corollary 9.6.1.22.

Remark 9.6.2.16. Let $\mathcal{C}$ be an ∞ -category. An object $X \in \mathcal{C}$ is subterminal if and only if 05F4
the diagram

$$X \xleftarrow{\mathrm{id}_X} X \xrightarrow{\mathrm{id}_X} X$$

exhibits X as a product of X with itself. See Remark 9.6.1.10.

Remark 9.6.2.17. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Then: 05F5

- If F preserves finite limits, then it carries discrete objects of $\mathcal{C}$ to discrete objects of $\mathcal{D}$
(see Remark 9.6.1.12).
- If F preserves pairwise products, then it carries subterminal objects of $\mathcal{C}$ to subterminal
objects of $\mathcal{D}$ (see Remark 9.6.2.16).

Notation 9.6.2.18 (The Heart of an ∞ -Category). Let $\mathcal{C}$ be an ∞ -category. We let $\mathcal{C}^\heartsuit$ 05F6
denote the full subcategory of $\mathcal{C}$ spanned by the discrete objects of $\mathcal{C}$. We will refer to $\mathcal{C}^\heartsuit$ as
the *heart* of the ∞ -category $\mathcal{C}$.

Let $\mathrm{Disc}(\mathcal{C})$ denote the homotopy category of $\mathcal{C}^\heartsuit$. By construction, the ∞ -category $\mathcal{C}^\heartsuit$
is locally discrete, so Remark 9.6.2.10 guarantees that the comparison map $\mathcal{C} \rightarrow \mathrm{N}_\bullet(\mathrm{h}\mathcal{C})$
restricts to a trivial Kan fibration

$$\mathcal{C}^\heartsuit \rightarrow \mathrm{N}_\bullet(\mathrm{Disc}(\mathcal{C})).$$

For this reason, we will often abuse terminology by identifying the heart $\mathcal{C}^\heartsuit$ with the ordinary
category $\mathrm{Disc}(\mathcal{C})$, which we also refer to as the *heart* of $\mathcal{C}$.

Notation 9.6.2.19. Let $\mathcal{C}$ be an ∞ -category. We let $\mathrm{Sub}(\mathcal{C})$ denote the collection of 04V9
isomorphism classes of subterminal objects of $\mathcal{C}$. If X is a subterminal object of $\mathcal{C}$, we let
 $[X] \in \mathrm{Sub}(\mathcal{C})$ denote its isomorphism class. Given a pair of subterminal objects X and X' ,
we write $[X] \subseteq [X']$ if there exists a morphism $f : X \rightarrow X'$ in the ∞ -category $\mathcal{C}$. Note that
the relation $\subseteq$ is a partial ordering on the set $\mathrm{Sub}(\mathcal{C})$.

Remark 9.6.2.20. Let $\mathcal{C}$ be an ∞ -category and let $\mathcal{C}' \subseteq \mathcal{C}$ be the full subcategory spanned 05F7
by the subterminal objects of $\mathcal{C}$. Then the construction $X \mapsto [X]$ induces a trivial Kan
fibration of ∞ -categories $\mathcal{C}' \rightarrow \mathrm{N}_\bullet(\mathrm{Sub}(\mathcal{C}))$. Stated more informally, the partially ordered
set $\mathrm{Sub}(\mathcal{C})$ can be identified with the full subcategory $\mathcal{C}' \subseteq \mathcal{C}$.

Remark 9.6.2.21. Let $\mathcal{C}$ be an ∞ -category. 04VA

- If $\mathcal{C}$ has a final object, then the partially ordered set $\text{Sub}(\mathcal{C})$ has a largest element: namely, the isomorphism class $[X]$, where X is any final object of $\mathcal{C}$.
- If $\mathcal{C}$ admits finite products, then $\text{Sub}(\mathcal{C})$ is a lower semilattice: that is, every finite subset of $\text{Sub}(\mathcal{C})$ has a greatest lower bound. In particular, every pair of elements $[X], [Y] \in \text{Sub}(\mathcal{C})$ have a greatest lower bound which we will denote by $[X] \cap [Y]$, given by the isomorphism class of the product $X \times Y$.

9.6.3 Truncated Morphisms

05F8 We now introduce a relative version of Definition 9.6.1.1.

05F9 **Definition 9.6.3.1.** Let $\mathcal{C}$ be an ∞ -category and let n be an integer. We say that a morphism $f : X \rightarrow Y$ of $\mathcal{C}$ is *n-truncated* if, for every object $C \in \mathcal{C}$, composition with the homotopy class $[f]$ induces an *n-truncated* morphism of Kan complexes $\text{Hom}_{\mathcal{C}}(C, X) \xrightarrow{[f]^\circ} \text{Hom}_{\mathcal{C}}(C, Y)$.

05FA **Remark 9.6.3.2.** In the situation of Definition 9.6.3.1, the composition map

$$\theta : \text{Hom}_{\mathcal{C}}(C, X) \xrightarrow{[f]^\circ} \text{Hom}_{\mathcal{C}}(C, Y)$$

is only well-defined up to homotopy (see Notation 4.6.9.15). However, the condition that θ is *n-truncated* depends only on its homotopy class (Remark 3.5.9.5).

05FB **Remark 9.6.3.3.** Let $f : X \rightarrow Y$ be a morphism in an ∞ -category $\mathcal{C}$. The condition that f is *n-truncated* depends only on the homotopy class $[f]$, regarded as a morphism in the homotopy category $\text{h}\mathcal{C}$.

05FC **Remark 9.6.3.4** (Monotonicity). Let $\mathcal{C}$ be an ∞ -category and let $m \leq n$ be integers. If $f : X \rightarrow Y$ is an *m-truncated* morphism of $\mathcal{C}$, then it is also *n-truncated*.

05FD **Example 9.6.3.5.** Let $\mathcal{C}$ be an ∞ -category. For $n \leq -2$, a morphism $f : X \rightarrow Y$ of $\mathcal{C}$ is *n-truncated* if and only if it is an isomorphism. See Example 3.5.9.2.

05FE **Example 9.6.3.6.** Let $f : X \rightarrow Y$ be a morphism of Kan complexes and let n be an integer. The following conditions are equivalent:

- (1) The morphism f is *n-truncated*, in the sense of Definition 3.5.9.1.
- (2) For every Kan complex K , composition with f induces an *n-truncated* morphism $\text{Fun}(K, X) \rightarrow \text{Fun}(K, Y)$.
- (3) For every simplicial set K , composition with f induces an *n-truncated* morphism $\text{Fun}(K, X) \rightarrow \text{Fun}(K, Y)$.

- (4) The morphism f is n -truncated when regarded as a morphism in the ∞ -category $\mathcal{S}$ of spaces, in the sense of Definition 9.6.3.1.

The implications (3) $\Rightarrow$ (2) $\Rightarrow$ (1) are immediate, the implication (1) $\Rightarrow$ (3) follows from Corollary 3.5.9.27, and the equivalence (2) $\Leftrightarrow$ (4) follows from Remark 5.5.1.5.

Proposition 9.6.3.7. *Let $\mathcal{C}$ be an ∞ -category, let n be an integer, and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. Then the morphism f is n -truncated (in the sense of Definition 9.6.3.1) if and only if it is n -truncated when regarded as an object of the slice ∞ -category $\mathcal{C}_{/Y}$ (in the sense of Definition 9.6.1.1).* 05FF

Proof. By definition, f is n -truncated as an object of $\mathcal{C}_{/Y}$ if and only if, for every morphism $g : C \rightarrow Y$ of $\mathcal{C}$, the morphism space $K = \mathrm{Hom}_{\mathcal{C}_{/Y}}(g, f)$ is n -truncated. Using Corollary 4.6.9.18, we can identify K with the homotopy fiber of the composition map $\mathrm{Hom}_{\mathcal{C}}(C, X) \xrightarrow{[f] \circ} \mathrm{Hom}_{\mathcal{C}}(C, Y)$ over the vertex $g \in \mathrm{Hom}_{\mathcal{C}}(C, Y)$. The desired result now follows from Corollary 3.5.9.12. $\square$

Corollary 9.6.3.8. *Let $\mathcal{C}$ be an ∞ -category, let n be an integer, and let $f : X \rightarrow Y$ be an n -truncated morphism of $\mathcal{C}$. Suppose we are given a diagram $F : K^{\triangleleft} \rightarrow \mathcal{C}_{/X}$. If the simplicial set K is $(n+1)$ -connective, then F is a limit diagram in $\mathcal{C}_{/X}$ if and only if the composition* 05YE

$$K^{\triangleleft} \rightarrow F\mathcal{C}_{/X} \rightarrow f_! \mathcal{C}_{/Y}$$

is a limit diagram, where $f_!$ is the functor given by composition with f (see Example 4.3.6.15). In particular, the functor $f_!$ preserves limits indexed by $(n+1)$ -connective simplicial sets.

Proof. Combine Proposition 9.6.3.7 with Corollary 9.6.1.22. $\square$

Corollary 9.6.3.9 (Homotopy Invariance). *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be an equivalence of ∞ -categories and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. Then f is n -truncated if and only if the image $F(f) : F(X) \rightarrow F(Y)$ is n -truncated.* 05FG

Proof. Using Corollary 4.6.4.21, we see that F induces an equivalence of ∞ -categories $\mathcal{C}_{/Y} \rightarrow \mathcal{D}_{/F(Y)}$. The desired result now follows by combining Proposition 9.6.3.7 with Remark 9.6.1.7. $\square$

Corollary 9.6.3.10. *Let $\mathcal{C}$ be an ∞ -category, let $n \geq 0$ be an integer, let $\square^{n+1}$ denote the simplicial cube of dimension $n+1$ (Notation 2.4.5.2), and let $y \in \square^{n+1}$ be the final vertex. Let $Q : \square^{n+1} \rightarrow \Delta^1$ be the morphism given on vertices by* 05FH

$$Q(v) = \begin{cases} 1 & \text{if } v = y \\ 0 & \text{otherwise.} \end{cases}$$

Then a morphism $f : X \rightarrow Y$ of $\mathcal{C}$ is $(n - 2)$ -truncated if and only if the composite map

$$\square^{n+1} \xrightarrow{Q} \Delta^1 \xrightarrow{f} \mathcal{C}$$

is a limit diagram in $\mathcal{C}$.

Proof. Let us identify $\square^{n+1}$ with the iterated join $\{x\} \star \text{Sd}(\partial\Delta^n) \star \{y\}$, where $\text{Sd}(\partial\Delta^n)$ denotes the subdivision of $\partial\Delta^n$ (see Proposition 3.3.3.17). Using Remark 7.1.3.12, we see that $f \circ Q$ is a limit diagram in $\mathcal{C}$ if and only if the constant map

$$\{x\} \star \text{Sd}(\partial\Delta^n) \rightarrow \{f\} \hookrightarrow \mathcal{C}_{/Y}$$

is a limit diagram in the slice ∞ -category $\mathcal{C}_{/Y}$. The desired result now follows by combining Proposition 9.6.3.7 with Remark 9.6.1.11. $\square$

05FJ Corollary 9.6.3.11. *Let $U : \mathcal{C} \rightarrow \mathcal{D}$ be a right fibration of ∞ -categories, let n be an integer, and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. Then f is n -truncated if and only if $U(f)$ is an n -truncated morphism of $\mathcal{D}$.*

Proof. Combine Corollaries 9.6.3.10 and 7.1.7.4. $\square$

05FK Corollary 9.6.3.12. *Let $\mathcal{C}$ be an ∞ -category and let n be an integer. Then the collection of n -truncated morphisms of $\mathcal{C}$ is closed under retracts (in the ∞ -category $\text{Fun}(\Delta^1, \mathcal{C})$).*

Proof. Combine Corollaries 9.6.3.10 and 8.5.1.12. $\square$

05FL Corollary 9.6.3.13. *Let $\mathcal{C}$ be an ∞ -category, let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$, and let $n \geq -2$ be an integer. Then f is n -truncated if and only if it satisfies the following condition for every positive integer $m \geq n + 4$:*

()_m If $\sigma : \Lambda_m^m \rightarrow \mathcal{C}$ is a diagram having the property that the composite map*

$$\Delta^1 \simeq N_\bullet(\{m - 1 < m\}) \hookrightarrow \Lambda_m^m \xrightarrow{\sigma} \mathcal{C}$$

is equal to f , then σ can be extended to an m -simplex of $\mathcal{C}$.

Proof. Combine Propositions 9.6.3.7 and 9.6.1.18. $\square$

05FM Proposition 9.6.3.14. *Let $\mathcal{C}$ be an ∞ -category, let n be an integer, and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. Then:*

- (1) *If Y is an n -truncated morphism and f is an n -truncated morphism, then X is an n -truncated object.*
- (2) *If X is an n -truncated object and Y is an $(n+1)$ -truncated object, then f is an n -truncated morphism.*

Proof. Let $C \in \mathcal{C}$ be an object and let $\theta : \mathrm{Hom}_{\mathcal{C}}(C, X) \rightarrow \mathrm{Hom}_{\mathcal{C}}(C, Y)$ be given by composition with the homotopy class $[f]$. Invoking Proposition 3.5.9.13, we obtain:

- (1_C) If the morphism space $\mathrm{Hom}_{\mathcal{C}}(C, Y)$ is n -truncated and θ is n -truncated, then the morphism space $\mathrm{Hom}_{\mathcal{C}}(C, X)$ is n -truncated.
- (2_C) If the morphism space $\mathrm{Hom}_{\mathcal{C}}(C, X)$ is n -truncated and the morphism space $\mathrm{Hom}_{\mathcal{C}}(C, Y)$ is $(n + 1)$ -truncated, then θ is n -truncated.

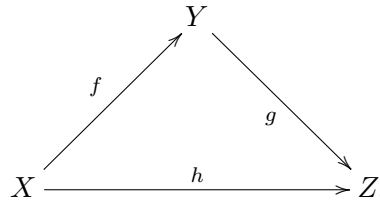

Proposition 9.6.3.14 follows by allowing the object C to vary. $\square$

Corollary 9.6.3.15. *Let $\mathcal{C}$ be an ∞ -category, let n be an integer, and let Y be an n -truncated object of $\mathcal{C}$. Then a morphism $f : X \rightarrow Y$ is n -truncated if and only if the object X is n -truncated.* 05FN

Proof. Combine Proposition 9.6.3.14 with Remark 9.6.3.4. $\square$

Example 9.6.3.16. Let $\mathcal{C}$ be an ∞ -category which contains a final object Y . Then every object $X \in \mathcal{C}$ admits a morphism $f : X \rightarrow Y$ which is uniquely determined up to homotopy. In this case, the object X is n -truncated (in the sense of Definition 9.6.1.1) if and only if the morphism f is n -truncated (in the sense of Definition 9.6.3.1). 05FP

Corollary 9.6.3.17 (Composition). *Let $\mathcal{C}$ be an ∞ -category containing a 2-simplex* 05FQ

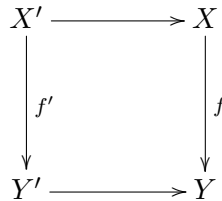

and let n be an integer. Then:

- (1) If the morphisms f and g are n -truncated, then the morphism h is n -truncated.
- (2) If the morphism h is n -truncated and the morphism g is $(n + 1)$ -truncated, then the morphism f is n -truncated.

Proof. Apply Proposition 9.6.3.14 to the slice ∞ -category $\mathcal{C}_{/Z}$ (see Proposition 9.6.3.7). $\square$

Proposition 9.6.3.18 (Pullbacks of Truncated Morphisms). *Let $\mathcal{C}$ be an ∞ -category* 05FR
containing a pullback diagram

and let n be an integer. If f is n -truncated, then f' is also n -truncated.

Proof. Let $C \in \mathcal{C}$ be an object. Applying Proposition 7.4.1.18, we obtain a pullback diagram

$$\begin{array}{ccc} \mathrm{Hom}_{\mathcal{C}}(C, X') & \longrightarrow & \mathrm{Hom}_{\mathcal{C}}(C, X) \\ \downarrow \theta' & & \downarrow \theta \\ \mathrm{Hom}_{\mathcal{C}}(C, Y') & \longrightarrow & \mathrm{Hom}_{\mathcal{C}}(C, Y) \end{array}$$

in the ∞ -category of spaces. Corollary 7.6.3.11 guarantees that if θ is n -truncated, then θ' is also n -truncated. Proposition 9.6.3.18 now follows by allowing the object C to vary. $\square$

05FS Proposition 9.6.3.19. *Let $\mathcal{C}$ be an ∞ -category, let $n \geq -1$ be an integer, and let X be an object of $\mathcal{C}$ for which there exists a product $X \times X$. Then X is n -truncated if and only if the diagonal map $\delta_X : X \rightarrow X \times X$ is $(n-1)$ -truncated.*

Proof. For each object $C \in \mathcal{C}$, Example 3.5.9.18 shows that the mapping space $\mathrm{Hom}_{\mathcal{C}}(C, X)$ is n -truncated if and only if the diagonal map

$$\mathrm{Hom}_{\mathcal{C}}(C, X) \rightarrow \mathrm{Hom}_{\mathcal{C}}(C, X) \times \mathrm{Hom}_{\mathcal{C}}(C, X)$$

is $(n-1)$ -truncated. The desired result now follows by allowing the object C to vary. $\square$

05FT Corollary 9.6.3.20. *Let $\mathcal{C}$ be an ∞ -category, let $n \geq -1$ be an integer, and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$ for which there exists a fiber product $X \times_Y X$. Then f is n -truncated if and only if the relative diagonal $\delta_{X/Y} : X \rightarrow X \times_Y X$ is $(n-1)$ -truncated (see Notation 7.6.2.15).*

Proof. Let us identify the morphism f with an object $\overline{X}$ of the slice ∞ -category $\mathcal{C}_{/Y}$. By virtue of Proposition 7.6.2.14, there exists a product $\overline{X} \times \overline{X}$ in the ∞ -category $\mathcal{C}_{/Y}$, whose image in $\mathcal{C}$ is the fiber product $X \times_Y X$. Moreover, the relative diagonal $\delta_{X/Y}$ can be identified with the image of the diagonal map $\delta_{\overline{X}} : \overline{X} \rightarrow \overline{X} \times \overline{X}$ under the forgetful functor $\mathcal{C}_{/Y} \rightarrow \mathcal{C}$. Applying Corollary 9.6.3.11, we see that $\delta_{X/Y}$ is an $(n-1)$ -truncated morphism of $\mathcal{C}$ if and only if $\delta_{\overline{X}}$ is an $(n-1)$ -truncated morphism of $\mathcal{C}_{/Y}$. By virtue of Proposition 9.6.3.19, this is equivalent to the requirement that $\overline{X}$ is n -truncated as an object of $\mathcal{C}_{/Y}$. The desired result now follows from the criterion of Proposition 9.6.3.7. $\square$

05FU Corollary 9.6.3.21. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Suppose that $\mathcal{C}$ admits pullbacks and that the functor F preserves pullbacks. Then, for every integer n , the functor F carries n -truncated morphisms of $\mathcal{C}$ to n -truncated morphisms of $\mathcal{D}$.*

Proof. For $n \leq -2$, a morphism is n -truncated if and only if it is an isomorphism (Example 9.6.3.5), so the desired result follows from Remark 1.5.1.6. The general case follows by induction on n , using Corollary 9.6.3.20. $\square$

9.6.4 Monomorphisms

Let $\mathcal{C}$ be a category. Recall that a morphism $f : X_0 \rightarrow X$ of $\mathcal{C}$ is a *monomorphism* if, for every object C of $\mathcal{C}$, the composition map

$$\mathrm{Hom}_{\mathcal{C}}(C, X_0) \xrightarrow{f \circ} \mathrm{Hom}_{\mathcal{C}}(C, X)$$

is injective. This notion has an obvious counterpart in the setting of ∞ -categories.

Definition 9.6.4.1. Let $\mathcal{C}$ be an ∞ -category and let $f : X_0 \rightarrow X$ be a morphism of $\mathcal{C}$. We say that f is a *monomorphism* if, for every object $C \in \mathcal{C}$, the composition map

$$\mathrm{Hom}_{\mathcal{C}}(C, X_0) \xrightarrow{[f] \circ} \mathrm{Hom}_{\mathcal{C}}(C, X)$$

induces a homotopy equivalence of $\mathrm{Hom}_{\mathcal{C}}(C, X_0)$ with a summand of $\mathrm{Hom}_{\mathcal{C}}(C, X)$.

Warning 9.6.4.2. Let $f : X_0 \rightarrow X$ be a morphism of Kan complexes. The assertion that f is a monomorphism can be given two different interpretations:

- (1) The map f is a monomorphism in the ordinary category of Set_{Δ} of simplicial sets.
- (2) The map f is a monomorphism in the ∞ -category $\mathcal{S}$ of spaces.

Beware that these conditions are unrelated to one another. Condition (2) is homotopy invariant: it is the requirement that f restricts to a homotopy equivalence of X_0 with a summand of X (Example 9.6.4.10). Condition (1) is very far from being homotopy invariant: we can always arrange that it is satisfied by replacing X by a homotopy equivalent Kan complex (see Exercise 3.1.7.11).

Notation 9.6.4.3. Let $\mathcal{C}$ be an ∞ -category and let f be a morphism of $\mathcal{C}$ having source X_0 and target X . If f is a monomorphism, we will sometimes visually emphasize this by denoting f with a hooked arrow (that is, we will write $f : X_0 \hookrightarrow X$ in place of $f : X_0 \rightarrow X$). Beware that this convention can be ambiguous in some situations (for example if $\mathcal{C} = \mathcal{S}$ is the ∞ -category of spaces; see Warning 9.6.4.2).

Variant 9.6.4.4. Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. We will say that f is an *epimorphism* if it is a monomorphism when viewed as a morphism of the ∞ -category $\mathcal{C}^{\mathrm{op}}$: that is, if the induced map

$$\mathrm{Hom}_{\mathcal{C}}(Y, C) \xrightarrow{\circ [f]} \mathrm{Hom}_{\mathcal{C}}(X, C)$$

induces a homotopy equivalence of $\mathrm{Hom}_{\mathcal{C}}(Y, C)$ with a summand of $\mathrm{Hom}_{\mathcal{C}}(X, C)$, for each object $C \in \mathcal{C}$. We will generally avoid this terminology, to avoid confusion with the notion of *quotient morphism* which we introduce in §10.3.2 (see Warning 10.3.2.10).

05FV **Remark 9.6.4.5.** Let $\mathcal{C}$ be an ∞ -category. Then a morphism $f : X_0 \rightarrow X$ is a monomorphism (in the sense of Definition 9.6.4.1) if and only if it is (-1) -truncated (in the sense of Definition 9.6.3.1). See Example 3.5.9.3.

04VH **Example 9.6.4.6.** Let $\mathcal{C}$ be a category and let $f : X_0 \rightarrow X$ be a morphism in $\mathcal{C}$. Then f is a monomorphism in the ∞ -category $\mathbf{N}_\bullet(\mathcal{C})$ (in the sense of Definition 9.6.4.1) if and only if it is a monomorphism in the usual category-theoretic sense.

04VJ **Example 9.6.4.7.** Let $\mathcal{C}$ be an ∞ -category and let $f : X_0 \rightarrow X$ be a morphism of $\mathcal{C}$. Then:

- If the object X is subterminal and f is a monomorphism, then the object X_0 is also subterminal.
- If the object X_0 is subterminal and the object X is discrete, then f is a monomorphism.

In particular, if X is subterminal, then f is a monomorphism if and only if X_0 is subterminal. See Proposition 9.6.3.14.

04VK **Example 9.6.4.8.** Let $\mathcal{C}$ be an ∞ -category containing a final object $\mathbf{1}$, and let X be an object of $\mathcal{C}$. Then there is a morphism $f : X \rightarrow \mathbf{1}$, which is uniquely determined up to homotopy. It follows from Example 9.6.4.7 that f is a monomorphism if and only if X is subterminal.

04VL **Example 9.6.4.9.** Let $\mathcal{C}$ be an ∞ -category. Then every isomorphism in $\mathcal{C}$ is a monomorphism.

05FW **Example 9.6.4.10.** Let $f : X_0 \rightarrow X$ be a map of Kan complexes. Then f is a monomorphism in the ∞ -category of spaces $\mathcal{S}$ if and only if it induces a homotopy equivalence of X_0 with a summand of X . See Example 9.6.1.4.

04VM **Warning 9.6.4.11.** Let $\mathcal{C}$ be an ∞ -category and let $i : X_0 \rightarrow X$ be a morphism of $\mathcal{C}$ which admits a left homotopy inverse $r : X \rightarrow X_0$. If $\mathcal{C}$ is (the nerve of) an ordinary category, then i is automatically a monomorphism. In general, this is not necessarily true. For example, let (X, x) be a pointed Kan complex, and regard the inclusion map $i : \{x\} \rightarrow X$ as a morphism in the ∞ -category $\mathcal{S}$ of spaces. Then i has a left homotopy inverse (given by the constant map $X \rightarrow \{x\}$). However, i is a monomorphism in the ∞ -category $\mathcal{S}$ only if x belongs to a contractible connected component of X (Example 9.6.4.10).

04VN **Remark 9.6.4.12.** Let $\mathcal{C}$ be an ∞ -category and let $f : X_0 \rightarrow X$ be a morphism in $\mathcal{C}$. If f is a monomorphism, then the homotopy class $[f] : X_0 \rightarrow X$ is a monomorphism in the ordinary category $\mathbf{h}\mathcal{C}$. Beware that the converse is false in general.

04VQ **Remark 9.6.4.13.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories and let $f : X_0 \rightarrow X$ be a morphism of $\mathcal{C}$.

- If F is fully faithful and $F(f)$ is a monomorphism in $\mathcal{D}$, then f is a monomorphism in $\mathcal{C}$.
- If F is an equivalence of ∞ -categories, then $F(f)$ is a monomorphism in $\mathcal{D}$ if and only if f is a monomorphism in $\mathcal{C}$.

Remark 9.6.4.14. Let $\mathcal{C}$ be an ∞ -category and let $f : X_0 \rightarrow X$ be a morphism of $\mathcal{C}$. The condition that f is a monomorphism depends only on the homotopy class $[f] \in \mathrm{Hom}_{\mathrm{h}\mathcal{C}}(X_0, X)$. 04VP

Remark 9.6.4.15. Let $\mathcal{C}$ be an ∞ -category, and suppose that we are given a commutative 04VR
diagram

$$\begin{array}{ccc} & Y & \\ f \nearrow & & \searrow g \\ X & \xrightarrow{h} & Z \end{array}$$

in $\mathcal{C}$, where g is a monomorphism. Then f is a monomorphism if and only if h is a monomorphism. In particular, the collection of monomorphisms is closed under composition. See Corollary 9.6.3.17.

Remark 9.6.4.16. Let $\mathcal{C}$ be an ∞ -category and let $f : X_0 \rightarrow X$ be a morphism of $\mathcal{C}$. 05FX
Then f is a monomorphism if and only if it is subterminal when viewed as an object of the ∞ -category $\mathcal{C}_{/X}$. See Proposition 9.6.3.7.

Remark 9.6.4.17. Let $\mathcal{C}$ be an ∞ -category and let $f : X_0 \rightarrow X$ be a morphism of $\mathcal{C}$. Then 05FY
 f is a monomorphism if and only if it satisfies the following condition for each $m \geq 3$:

($*_m$) Let $\sigma : \Lambda_m^m \rightarrow \mathcal{C}$ be a morphism of simplicial sets for which the composition

$$\Delta^1 \simeq N_\bullet(\{m-1 < m\}) \subset \Lambda_m^m \xrightarrow{\sigma} \mathcal{C}$$

coincides with f . Then σ can be extended to an m -simplex of $\mathcal{C}$.

This follows by combining Remarks 9.6.2.14 and 9.6.4.16.

Remark 9.6.4.18. Let $\mathcal{C}$ be an ∞ -category, let $f : X_0 \rightarrow X$ be a morphism of $\mathcal{C}$, and let σ 05FZ
denote the composite map

$$\Delta^1 \times \Delta^1 \xrightarrow{(i,j) \mapsto ij} \Delta^1 \xrightarrow{u} \mathcal{C},$$

which we depict as a diagram

$$\begin{array}{ccc} X_0 & \xrightarrow{\text{id}} & X_0 \\ \downarrow \text{id} & & \downarrow f \\ X_0 & \xrightarrow{f} & X. \end{array}$$

Then f is a monomorphism if and only if σ is a pullback square in $\mathcal{C}$. This follows by combining Remarks 9.6.4.16 and 9.6.2.16 (see Proposition 7.6.2.14).

04VX **Remark 9.6.4.19.** Let $\mathcal{C}$ be an ∞ -category which admits pullbacks. Stated more informally, Remark 9.6.4.18 asserts that a morphism $f : X_0 \rightarrow X$ of $\mathcal{C}$ is a monomorphism if and only if the relative diagonal $\delta_{X_0/X} : X_0 \rightarrow X_0 \times_X X_0$ is an isomorphism.

05YF **Variant 9.6.4.20.** Let $\mathcal{C}$ be an ∞ -category and suppose we are given a commutative diagram

$$\begin{array}{ccc} Y_{\pm} & \longrightarrow & Y_{+} \\ \downarrow & & \downarrow \\ Y_{-} & \longrightarrow & X_0 \\ & \searrow u & \downarrow \\ & & X \end{array}$$

in $\mathcal{C}$. If u is a monomorphism, then the upper left square is a pullback diagram if and only if the outer square is a pullback diagram. This follows from Corollary 9.6.3.8 (combined with the characterization of pullback diagrams supplied by Proposition 7.6.2.14).

From the criterion of Remark 9.6.4.18, we immediately obtain the following:

05G0 **Proposition 9.6.4.21.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories which preserves pullbacks. Then F carries monomorphisms in $\mathcal{C}$ to monomorphisms in $\mathcal{D}$.

04W1 **Remark 9.6.4.22.** In the statement of Proposition 9.6.4.21, it is not necessary to assume that the ∞ -categories $\mathcal{C}$ and $\mathcal{D}$ admit pullbacks (we only need to know that F preserves those pullback squares which exist in $\mathcal{C}$).

04W2 **Example 9.6.4.23.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories which admits a left adjoint. Then F carries subterminal objects of $\mathcal{C}$ to subterminal objects of $\mathcal{D}$, and carries monomorphisms in $\mathcal{C}$ to monomorphisms in $\mathcal{D}$. This follows from Proposition 9.6.4.21 and Remark 9.6.2.17, since F preserves limit diagrams (Corollary 7.1.4.23).

Remark 9.6.4.24. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a right fibration of ∞ -categories and let f be a morphism in $\mathcal{C}$. Then f is a monomorphism if and only if $F(f)$ is a monomorphism in the ∞ -category $\mathcal{D}$. See Corollary 9.6.3.11. 05G1

Remark 9.6.4.25. Let $\mathcal{C}$ be an ∞ -category and let $f : X \hookrightarrow Y$ be a monomorphism in $\mathcal{C}$. If $f' : X' \rightarrow Y'$ is a retract of f (in the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$), then f' is also a monomorphism. See Corollary 9.6.3.12. 05G2

Definition 9.6.4.26. Let $\mathcal{C}$ be an ∞ -category and let X be an object of $\mathcal{C}$. A *subobject* of X is a subterminal object of the slice ∞ -category $\mathcal{C}_{/X}$: that is, an object which is given by a monomorphism $f : X_0 \hookrightarrow X$ in the ∞ -category $\mathcal{C}$ (see Remark 9.6.4.16). In this situation, we will sometimes abuse terminology by referring to X_0 as a *subobject* of X and writing $X_0 \subseteq X$; in this case, we implicitly assume that a monomorphism $X_0 \hookrightarrow X$ has been specified. 04W8

Notation 9.6.4.27. Let $\mathcal{C}$ be an ∞ -category and let X be an object of $\mathcal{C}$. We let $\mathrm{Sub}(X)$ denote the set $\mathrm{Sub}(\mathcal{C}_{/X})$ of isomorphism classes of subterminal objects of $\mathcal{C}_{/X}$ (see Notation 9.6.2.19). If $f : X_0 \hookrightarrow X$ is a monomorphism, we write $[X_0] \in \mathrm{Sub}(X)$ for the isomorphism class of f . We will sometimes abuse notation by identifying the isomorphism class $[X_0]$ with the object X_0 itself: by virtue of Remark 9.6.2.20, this identification is essentially harmless provided that X_0 is understood as an object of the slice ∞ -category $\mathcal{C}_{/X}$ (that is, provided that we remember the data of the monomorphism f). We will refer to $\mathrm{Sub}(X)$ as the *set of subobjects* of X , and we endow it with the partial ordering described in Notation 9.6.2.19: that is, if $f_0 : X_0 \hookrightarrow X$ and $f_1 : X_1 \hookrightarrow X$ are monomorphisms, we write $[X_0] \subseteq [X_1]$ if there exists a 2-simplex 04W9

$$\begin{array}{ccc} X_0 & \xrightarrow{g} & X_1 \\ & \searrow f_0 \quad \swarrow f_1 & \\ & X & \end{array}$$

in the ∞ -category $\mathcal{C}$. In this case, g is automatically a monomorphism (see Remark 9.6.4.15).

Example 9.6.4.28. Let X be a Kan complex, which we regard as an object of the ∞ -category $\mathcal{S}$. Using Example 9.6.4.10, we can identify $\mathrm{Sub}(X)$ with the partially ordered collection of all summands of X . Alternatively, we can identify $\mathrm{Sub}(X)$ with the collection of all subsets of the set $\pi_0(X)$ (see Exercise 1.2.1.16). 04WA

Remark 9.6.4.29. Let $\mathcal{C}$ be an ∞ -category. For every object $X \in \mathcal{C}$, the identity morphism $\mathrm{id}_X : X \rightarrow X$ is a monomorphism (Example 9.6.4.9), so we can regard X as a subobject of itself. Moreover, the isomorphism class $[X]$ is a largest element of the partially ordered set $\mathrm{Sub}(X)$ (see Remark 9.6.2.21). 04WB

04WC **Remark 9.6.4.30.** Let $\mathcal{C}$ be an ∞ -category which admits fiber products. Then, for every object $X \in \mathcal{C}$, the slice ∞ -category $\mathcal{C}_{/X}$ admits finite products (Corollary 7.6.2.17). It follows that the partially ordered set $\text{Sub}(X)$ is a lower semilattice (see Remark 9.6.2.21). In particular, every pair of objects $[X_0], [X_1] \in \text{Sub}(X)$ have a greatest lower bound $[X_0] \cap [X_1]$ in $\text{Sub}(X)$, given concretely by the isomorphism class of the fiber product $[X_0 \times_X X_1]$.

04WD **Remark 9.6.4.31** (Pullbacks of Monomorphisms). Let $\mathcal{C}$ be an ∞ -category containing a commutative diagram

04WE

$$\begin{array}{ccc} X_0 & \longrightarrow & Y_0 \\ \downarrow i & & \downarrow j \\ X & \xrightarrow{f} & Y, \end{array} \quad (9.32)$$

where $j : Y_0 \rightarrow Y$ is a monomorphism. Then (9.32) is a pullback square if and only if the following conditions are satisfied:

- The morphism $i : X_0 \rightarrow X$ is also a monomorphism.
- The diagram (9.32) determines a pullback square in the homotopy category $\text{h}\mathcal{C}$. That is, a morphism $g : C \rightarrow X_0$ factors (up to homotopy) through i if and only if the $f \circ g$ factors (up to homotopy) through j .

In particular, the collection of monomorphisms in $\mathcal{C}$ is closed under pullbacks.

04WF **Construction 9.6.4.32** (Inverse Images). Let $\mathcal{C}$ be an ∞ -category which admits fiber products. Then every morphism $f : X \rightarrow Y$ in $\mathcal{C}$ determines a pullback functor

$$f^* : \mathcal{C}_{/Y} \rightarrow \mathcal{C}_{/X} \quad Y' \mapsto X \times_Y Y'$$

(see Proposition 7.6.2.24). The functor f^* has a left adjoint, and therefore carries subterminal objects of $\mathcal{C}_{/X}$ to subterminal objects of $\mathcal{C}_{/Y}$. Passing to isomorphism classes, we obtain a map of partially ordered sets $f^{-1} : \text{Sub}(Y) \rightarrow \text{Sub}(X)$, given concretely by the formula $f^{-1}[Y_0] = [Y_0 \times_Y X]$. Since the functor f^* preserves products, f^{-1} is a homomorphism of lower semilattices: that is, it satisfies the identities

$$f^{-1}([Y_0] \cap [Y_1]) = f^{-1}([Y_0]) \cap f^{-1}([Y_1]) \quad f^{-1}([Y]) = [X].$$

We close this section with a discussion of monomorphisms in the ∞ -category $\mathcal{QC}$ of (small) ∞ -categories.

04W5 **Proposition 9.6.4.33.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. The following conditions are equivalent:

- (1) *The functor F is a monomorphism in the ∞ -category $\mathcal{QC}$.*
- (2) *For every pair of objects $X, Y \in \mathcal{C}$, the functor F induces a homotopy equivalence from $\mathrm{Hom}_{\mathcal{C}}(X, Y)$ to a summand of $\mathrm{Hom}_{\mathcal{D}}(F(X), F(Y))$ which contains every isomorphism from $F(X)$ to $F(Y)$.*
- (3) *The functor F induces an equivalence from $\mathcal{C}$ to a replete subcategory $\mathcal{D}_0 \subseteq \mathcal{D}$.*

Proof. We first show that (1) implies (2). By virtue of Corollary 4.5.2.24, we may assume without loss of generality that F is an isofibration of ∞ -categories. In this case, it follows from Exercise 7.6.3.13 that the diagonal inclusion $\delta : \mathcal{C} \hookrightarrow \mathcal{C} \times_{\mathcal{D}} \mathcal{C}$ (formed in the ordinary category of simplicial sets) can be identified with the relative diagonal of F in the ∞ -category $\mathcal{QC}$. Combining this observation with Remark 9.6.4.18, we deduce that F is a monomorphism (in the ∞ -category $\mathcal{QC}$) if and only if δ is an equivalence of ∞ -categories. In particular, if F is a monomorphism, then δ is fully faithful: that is, for every pair of objects $X, Y \in \mathcal{C}$, the induced map

$$\mathrm{Hom}_{\mathcal{C}}(X, Y) \rightarrow \mathrm{Hom}_{\mathcal{C} \times_{\mathcal{D}} \mathcal{C}}(\delta(X), \delta(Y)) \simeq \mathrm{Hom}_{\mathcal{C}}(X, Y) \times_{\mathrm{Hom}_{\mathcal{D}}(F(X), F(Y))} \mathrm{Hom}_{\mathcal{C}}(X, Y)$$

is a homotopy equivalence. Our assumption that F is an isofibration guarantees that the map $F_{X,Y} : \mathrm{Hom}_{\mathcal{C}}(X, Y) \rightarrow \mathrm{Hom}_{\mathcal{D}}(F(X), F(Y))$ is Kan fibration (Proposition 4.6.1.21). Applying Corollary 3.5.1.31, we deduce that $F_{X,Y}$ restricts to a homotopy equivalence of $\mathrm{Hom}_{\mathcal{C}}(X, Y)$ with a summand of $\mathrm{Hom}_{\mathcal{D}}(F(X), F(Y))$. To complete the proof, it will suffice to show that this summand contains every isomorphism from $F(X)$ to $F(Y)$. In fact, we will prove something more precise: the induced map of cores $F^{\simeq} : \mathcal{C}^{\simeq} \rightarrow \mathcal{D}^{\simeq}$ is a trivial Kan fibration from $\mathcal{C}^{\simeq}$ to a summand of $\mathcal{D}^{\simeq}$. This follows again from Corollary 3.5.1.31, since $F^{\simeq}$ is a Kan fibration (Proposition 4.4.3.7).

We now show that (2) implies (3). As above, we may assume that F is an isofibration. Let $\mathrm{h}\mathcal{C}$ and $\mathrm{h}\mathcal{D}$ denote the homotopy categories of $\mathcal{C}$ and $\mathcal{D}$, respectively. We define a subcategory $\mathrm{h}\mathcal{D}_0 \subseteq \mathrm{h}\mathcal{D}$ as follows:

- An object $\overline{X}$ of $\mathrm{h}\mathcal{D}$ belongs to the subcategory $\mathrm{h}\mathcal{D}_0$ if and only if it is the image of an object X of $\mathrm{h}\mathcal{C}$.
- A morphism $\overline{u} : \overline{X} \rightarrow \overline{Y}$ of $\mathrm{h}\mathcal{D}$ belongs to the subcategory $\mathrm{h}\mathcal{D}_0$ if and only if it is the image of a morphism u of $\mathrm{h}\mathcal{C}$.

We first claim that the subcategory $\mathrm{h}\mathcal{D}_0$ is well-defined: that is, if $\overline{u} : \overline{X} \rightarrow \overline{Y}$ and $\overline{v} : \overline{Y} \rightarrow \overline{Z}$ are composable morphisms of $\mathrm{h}\mathcal{D}$ which can be lifted to morphisms $u : X \rightarrow Y$ and $v : Y' \rightarrow Z$ of $\mathrm{h}\mathcal{C}$, then the composite morphism $\overline{v} \circ \overline{u}$ has the same property. Assumption (2) guarantees that the identity morphism $\mathrm{id}_{\overline{Y}}$ belongs to the image of the map

$$\mathrm{Hom}_{\mathrm{h}\mathcal{C}}(Y, Y') = \pi_0(\mathrm{Hom}_{\mathcal{C}}(Y, Y')) \rightarrow \pi_0(\mathrm{Hom}_{\mathcal{D}}(\overline{Y}, \overline{Y})) \simeq \mathrm{Hom}_{\mathrm{h}\mathcal{D}}(\overline{Y}, \overline{Y}).$$

That is, there exists a morphism $e : Y \rightarrow Y'$ in $\mathbf{h}\mathcal{C}$ satisfying $F(e) = \mathrm{id}_{\overline{Y}}$. Replacing v by the composition $v \circ e$, we can arrange that $Y = Y'$: that is, that u and v are composable morphisms in the category $\mathbf{h}\mathcal{C}$. It then follows that $\overline{v} \circ \overline{u} = F(v \circ u)$ is also morphism of $\mathbf{h}\mathcal{D}_0$, as desired.

By virtue of Proposition 4.1.2.10, the subcategory $\mathbf{h}\mathcal{D}_0 \subseteq \mathbf{h}\mathcal{D}$ is the homotopy category of a (unique) subcategory $\mathcal{D}_0 \subseteq \mathcal{D}$. Using condition (2), we see that the subcategory $\mathcal{D}_0$ is replete. By construction, the functor F factors as a composition $\mathcal{C} \xrightarrow{F_0} \mathcal{D}_0 \hookrightarrow \mathcal{D}$. For every pair of objects $X, Y \in \mathcal{C}$, we can identify $\mathrm{Hom}_{\mathcal{D}_0}(F(X), F(Y))$ with the summand of $\mathrm{Hom}_{\mathcal{D}}(F(X), F(Y))$ given by the essential image of $F_{X,Y}$. Invoking assumption (2), we see that the functor F_0 is fully faithful. By construction, F_0 is also surjective on objects, and is therefore an equivalence of ∞ -categories (Theorem 4.6.2.21). This completes the proof of the implication (2) $\Rightarrow$ (3).

We now show that (3) implies (1). Assume that F induces an equivalence from $\mathcal{C}$ to a replete subcategory $\mathcal{D}_0 \subseteq \mathcal{C}$; we wish to show that F is a monomorphism. By virtue of Remark 9.6.4.15 (and Example 9.6.4.9), it will suffice to show that the inclusion map $\iota : \mathcal{D}_0 \hookrightarrow \mathcal{D}$ is a monomorphism in $\mathcal{QC}$. Fix an ∞ -category $\mathcal{B}$, so that composition with the homotopy class $[\iota]$ induces a map of Kan complexes $\theta : \mathrm{Hom}_{\mathcal{QC}}(\mathcal{B}, \mathcal{D}_0) \rightarrow \mathrm{Hom}_{\mathcal{QC}}(\mathcal{B}, \mathcal{D})$. We wish to show that θ induces a homotopy equivalence from $\mathrm{Hom}_{\mathcal{QC}}(\mathcal{B}, \mathcal{D}_0)$ to a summand of $\mathrm{Hom}_{\mathcal{QC}}(\mathcal{B}, \mathcal{D})$. By virtue of Remark 5.5.4.5, it will suffice to prove the analogous assertion for the inclusion map $\mathrm{Fun}(\mathcal{B}, \mathcal{D}_0)^\simeq \hookrightarrow \mathrm{Fun}(\mathcal{B}, \mathcal{D})^\simeq$, which follows immediately from Corollary 4.4.3.13. $\square$

04W6 Corollary 9.6.4.34. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a fully faithful functor of ∞ -categories. Then F is a monomorphism in the ∞ -category $\mathcal{QC}$.*

Proof. Let $\mathcal{D}_0 \subseteq \mathcal{D}$ be the essential image of F . By virtue of Proposition 9.6.4.33, it will suffice to show that F induces an equivalence from $\mathcal{C}$ to $\mathcal{D}_0$, which is a reformulation of the requirement that F is fully faithful (Corollary 4.6.2.23). $\square$

04W7 Warning 9.6.4.35. Let $\mathcal{C}$ be an ∞ -category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a subcategory. Beware that, if we do not assume that $\mathcal{C}_0$ is replete (or full), then the inclusion functor $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ need not be a monomorphism in $\mathcal{QC}$. For example, suppose that $\mathcal{C} = \mathbf{N}_\bullet(\mathcal{D})$ is the nerve of a category $\mathcal{D}$. Then the 0-skeleton $\mathcal{C}_0 = \mathrm{sk}_0(\mathcal{C})$ is always subcategory of $\mathcal{C}$ (namely, the subcategory spanned by the identity morphisms of $\mathcal{C}$). However, the inclusion $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ is a monomorphism in $\mathcal{QC}$ if and only if every isomorphism in $\mathcal{D}$ is an identity morphism.

Chapter 10

Exactness and Animation

10.1 Sifted ∞ -Categories

04QH

10.1.1 Sifted Simplicial Sets

05YG

We now introduce a useful enlargement of the class of filtered ∞ -categories.

02QD

Definition 10.1.1.1. Let K be a simplicial set. We say that K is *sifted* if, for every finite set I , the diagonal map $K \rightarrow K^I$ is right cofinal. If $\mathcal{C}$ is an ∞ -category, we say that a diagram $K \rightarrow \mathcal{C}$ is *sifted* if the simplicial set K is sifted. 02QE

Warning 10.1.1.2. Definition 10.1.1.1 has a counterpart in classical category theory. In [2], Adámek and Rosický define a *sifted category* to be a nonempty category $\mathcal{C}$ which satisfies the following condition: 02QF

(*) For every pair of objects $X, Y \in \mathcal{C}$, the nerve of the category $\mathcal{C}_{X/} \times_{\mathcal{C}} \mathcal{C}_{Y/}$ is connected.

It follows from Corollary 10.1.1.9 below that if the simplicial set $N_{\bullet}(\mathcal{C})$ is sifted (in the sense of Definition 10.1.1.1), then the category $\mathcal{C}$ satisfies condition (*). Beware that the converse is false (see Exercise 10.1.1.11). In other words, Definition 10.1.1.1 is not a generalization of the classical notion of a sifted category (instead, it generalizes the notion of a *homotopy sifted* category, introduced by Rosický in [52]).

Variant 10.1.1.3. Let K be a simplicial set. We say that K is *cosifted* if, for every finite set I , the diagonal map $K \rightarrow K^I$ is left cofinal. Equivalently, K is cosifted if and only if the opposite simplicial set K^{op} is sifted. 02QG

Example 10.1.1.4. Every filtered ∞ -category $\mathcal{C}$ is sifted (see Proposition 9.1.1.18). In particular, if $\mathcal{C}$ is an ∞ -category which contains a final object, then $\mathcal{C}$ is sifted (see Example 9.1.1.6). 02QH

02QJ **Proposition 10.1.1.5.** *Let $f : K \rightarrow K'$ be a right cofinal morphism of simplicial sets. If K is sifted, then K' is also sifted.*

Proof. Fix a finite set I . We have a commutative diagram of simplicial sets

$$\begin{array}{ccc} K & \xrightarrow{\delta_K} & K^I \\ \downarrow f & & \downarrow f^I \\ K' & \xrightarrow{\delta_{K'}} & K'^I, \end{array}$$

where the vertical maps are right cofinal (Corollary 7.2.1.20). Our assumption that K is sifted guarantees that δ_K is right cofinal, so that $\delta_{K'}$ is also right cofinal (Proposition 7.2.1.6). $\square$

02QK **Proposition 10.1.1.6.** *Let $f : K \rightarrow K'$ be a categorical equivalence of simplicial sets. Then K is sifted if and only if K' is sifted.*

Proof. It will suffice to show that, for every finite set I , the diagonal map $\delta_K : K \rightarrow K^I$ is right cofinal if and only if the diagonal map $\delta_{K'} : K' \rightarrow K'^I$ is right cofinal. This follows by applying Corollary 7.2.1.22 to the commutative diagram

$$\begin{array}{ccc} K & \xrightarrow{\delta_K} & K^I \\ \downarrow f & & \downarrow f^I \\ K' & \xrightarrow{\delta_{K'}} & K'^I. \end{array}$$

$\square$

02QL **Proposition 10.1.1.7.** *Every sifted simplicial set is weakly contractible.*

Proof. Let K be a sifted simplicial set. Taking $I = \emptyset$ in Definition 10.1.1.1, we conclude that the projection map $K \rightarrow \Delta^0$ is right cofinal, so that K is weakly contractible by virtue of Proposition 7.2.1.5. $\square$

02QM **Proposition 10.1.1.8.** *Let K be a simplicial set. Then K is sifted if and only if it is nonempty and the diagonal map $\delta : K \hookrightarrow K \times K$ is right cofinal.*

Proof. It follows immediately from the definition that if K is sifted, then the diagonal map $\delta : K \hookrightarrow K \times K$ is right cofinal. Moreover, Proposition 7.2.1.5 guarantees that K is weakly contractible, and therefore nonempty.

For the converse, assume that K is nonempty and that δ is right cofinal. We wish to prove that, for every finite set I , the map $\delta_I : K \rightarrow K^I$ is right cofinal. The proof proceeds by induction on the cardinality of I . We first treat the case where $I = \emptyset$. Note that our assumption that δ is right cofinal guarantees in particular that it is a weak homotopy equivalence (Proposition 7.2.1.5). Since K is nonempty, it follows that K is weakly contractible (Corollary 3.5.1.33). Applying Proposition 7.2.1.5 again, we deduce that the projection map $K \rightarrow \Delta^0$ is right cofinal, as desired.

We now carry out the inductive step. Assume that the set I is nonempty. Choose an element $i \in I$, and set $J = I \setminus \{i\}$. Unwinding the definitions, we see that δ_I can be identified with the composition

$$K \xrightarrow{\delta} K \times K \xrightarrow{\text{id}_K \times \delta_J} K \times K^J.$$

Our inductive hypothesis guarantees that δ_J is right cofinal, so that the product map $\text{id}_K \times \delta_J$ is also right cofinal (Corollary 7.2.1.19). Since the collection of right cofinal morphisms is closed under composition (Proposition 7.2.1.6), it follows that δ_I is also right cofinal. $\square$

Corollary 10.1.1.9. *Let $\mathcal{C}$ be an ∞ -category. Then $\mathcal{C}$ is sifted if and only if it is nonempty and, for every pair of objects $X, Y \in \mathcal{C}$, the ∞ -category $\mathcal{C}_{X/} \times_{\mathcal{C}} \mathcal{C}_{Y/}$ is weakly contractible.* 02QN

Proof. Combine Proposition 10.1.1.8 with Theorem 7.2.3.1. $\square$

We now consider an important example.

Proposition 10.1.1.10. *Let Δ be the simplex category (Definition 1.1.0.2). Then the ∞ -category $\mathbf{N}_{\bullet}(\Delta)$ is cosifted.* 02QP

Proof. We use the criterion of Corollary 10.1.1.9. Since the category Δ is nonempty, it will suffice to show that for every pair of nonnegative integers $m, n \geq 0$, the simplicial set

$$\mathbf{N}(\Delta)_{/[m]} \times_{\mathbf{N}(\Delta)} \mathbf{N}(\Delta)_{/[n]} \simeq \mathbf{N}(\Delta_{/[m]} \times_{\Delta} \Delta_{/[n]})$$

is weakly contractible. Unwinding the definitions, we can identify $\Delta_{/[m]} \times_{\Delta} \Delta_{/[n]}$ with the category of simplices Δ_S of Construction 1.1.3.9, where S is the product $\Delta^m \times \Delta^n$. Note that S can be identified with the nerve of a partially ordered set, and is therefore a braced simplicial set (Exercise 3.3.1.2). Let Δ_S^{nd} denote the full subcategory of Δ_S spanned by the nondegenerate simplices of S (Notation 3.3.3.12), so that the inclusion $\Delta_S^{\text{nd}} \hookrightarrow \Delta_S$ admits a left adjoint (Exercise 3.3.3.16). It follows that the inclusion map $\mathbf{N}_{\bullet}(\Delta_S^{\text{nd}}) \hookrightarrow \mathbf{N}_{\bullet}(\Delta_S)$ is a homotopy equivalence of simplicial sets (Proposition 3.1.6.9). It will therefore suffice to show that the nerve $\mathbf{N}_{\bullet}(\Delta_S^{\text{nd}})$ is weakly contractible. Using Proposition 3.3.3.17, we can identify $\mathbf{N}_{\bullet}(\Delta_S^{\text{nd}})$ with the subdivision $\text{Sd}(S)$, so that Construction 3.3.4.3 supplies a weak homotopy equivalence $\lambda_S : \mathbf{N}_{\bullet}(\Delta_S^{\text{nd}}) \rightarrow S$. We conclude by observing that the simplicial set $S = \Delta^m \times \Delta^n$ is weakly contractible (in fact, it is contractible, since it is the nerve of a partially ordered set having a smallest element). $\square$

02QQ **Exercise 10.1.1.11.** Let $\Delta_{\leq 1}$ denote the full subcategory of Δ spanned by the objects $[0]$ and $[1]$, which we depict informally as a diagram

$$[0] \begin{array}{c} \xrightarrow{\quad} \\ \xrightarrow{\quad} \\ \xrightarrow{\quad} \end{array} [1].$$

Show that:

- The opposite category $\Delta_{\leq 1}^{\text{op}}$ satisfies condition $(*)$ of Warning 10.1.1.2 (that is, it is a sifted category in the sense of [2]).
- The simplicial set $N_{\bullet}(\Delta_{\leq 1}^{\text{op}})$ is not sifted.

10.2 Simplicial Objects of ∞ -Categories

04QJ Let $\mathcal{C}$ be a category. Recall that a simplicial object of $\mathcal{C}$ is a functor $\Delta^{\text{op}} \rightarrow \mathcal{C}$, where Δ is the simplex category introduced in Definition 1.1.0.2. This notion has an obvious counterpart in the setting of ∞ -categories:

04QK **Definition 10.2.0.1** (Simplicial Objects). Let $\mathcal{C}$ be an ∞ -category. A *simplicial object* of $\mathcal{C}$ is a functor from the ∞ -category $N_{\bullet}(\Delta^{\text{op}})$ to $\mathcal{C}$. A *cosimplicial object* of $\mathcal{C}$ is a functor from $N_{\bullet}(\Delta)$ to $\mathcal{C}$.

04QL **Notation 10.2.0.2.** Let $\mathcal{C}$ be an ∞ -category. We will often use the notation $X_{\bullet}$ to indicate a simplicial object of $\mathcal{C}$. In this case, we write X_n for the value of the functor $X_{\bullet}$ on the object $[n] \in \Delta^{\text{op}}$. Similarly, we often use an expression like $X^{\bullet}$ to indicate a cosimplicial object of $\mathcal{C}$, and X^n for its value on the object $[n] \in \Delta$.

04QM **Example 10.2.0.3.** Let $\mathcal{C}$ be a category. Then (co)simplicial objects of the ∞ -category $N_{\bullet}(\mathcal{C})$ (in the sense of Definition 10.2.0.1) can be identified with (co)simplicial objects of $\mathcal{C}$ (in the sense of Definition 1.1.0.4).

04QN **Notation 10.2.0.4** (Face and Degeneracy Operators). Let $X_{\bullet}$ be a simplicial object of an ∞ -category $\mathcal{C}$. For every pair of integers $0 \leq i \leq n$, we let $s_i^n : X_n \rightarrow X_{n+1}$ denote the morphism induced by the surjection $\sigma_n^i : [n+1] \twoheadrightarrow [n]$ of Construction 1.1.2.1; we will refer to s_i^n as the *i th degeneracy operator* for the simplicial object $X_{\bullet}$. If $n > 0$, we let $d_i^n : X_n \rightarrow X_{n-1}$ denote the morphism induced by the inclusion of linearly ordered sets $\delta_n^i : [n-1] \hookrightarrow [n]$ introduced in Construction 1.1.1.4. We will refer to d_i^n as the *i th face operator* of $X_{\bullet}$.

04QP **Warning 10.2.0.5.** If $\mathcal{C}$ is an ordinary category, then a simplicial object $X_{\bullet}$ of $\mathcal{C}$ is completely determined by the collection of objects $\{X_n\}_{n \geq 0}$, together with the face and degeneracy operators

$$d_i^n : X_n \rightarrow X_{n-1} \quad s_i^n : X_n \rightarrow X_{n+1}$$

(see Proposition 1.1.2.14). In the setting of ∞ -categories, this is no longer true.

10.2.1 Geometric Realization

Let S be a simplicial set. Recall that the *geometric realization* of S is a topological space $|S|$ which corepresents the functor

$$(X \in \mathbf{Top}) \mapsto \mathrm{Hom}_{\mathbf{Set}_\Delta}(S, \mathrm{Sing}_\bullet(X));$$

here $\mathbf{Top}$ denotes the category whose objects are topological spaces and whose morphisms are continuous functions (Definition 1.2.3.1). This property determines the topological space $|S|$ up to homeomorphism: that is, up to isomorphism in the category $\mathbf{Top}$. We now formulate a homotopy-invariant counterpart of this universal property, which determines the topological space $|S|$ up to homotopy equivalence (rather than homeomorphism). In what follows, we regard $\mathbf{Top}$ as a simplicially enriched category (see Example 2.4.1.5), and we let $N_\bullet^{\mathrm{hc}}(\mathbf{Top})$ denote its homotopy coherent nerve.

Proposition 10.2.1.1. *Let S be a simplicial set. Then the geometric realization $|S|$ is a colimit of the diagram*

$$N_\bullet(\Delta^{\mathrm{op}}) \xrightarrow{S} N_\bullet(\mathbf{Set}) \subset N_\bullet^{\mathrm{hc}}(\mathbf{Top}).$$

Proposition 10.2.1.1 admits a more combinatorial formulation:

Variant 10.2.1.2. Let $S = S_\bullet$ be a simplicial set. Then the Kan complex $\mathrm{Sing}_\bullet(|S|)$ is a colimit of the diagram

$$N_\bullet(\Delta^{\mathrm{op}}) \xrightarrow{S} N_\bullet(\mathbf{Set}) \subset S.$$

Proof of Variant 10.2.1.2. Let $\mathbf{Kan}$ denote the ordinary category of Kan complexes, and let $\mathcal{F} : \Delta^{\mathrm{op}} \rightarrow \mathbf{Kan}$ be the functor which carries each object $[n] \in \Delta^{\mathrm{op}}$ to the set of n -simplices S_n (regarded as a constant simplicial set). Let $\mathrm{holim}_{\rightarrow}(\mathcal{F})$ denote the homotopy colimit of the diagram $\mathcal{F}$ (Construction 5.3.2.1). By virtue of Proposition 7.5.7.1 (and Example 1.4.2.5), it will suffice to show that there is a weak homotopy equivalence of simplicial sets $v : \mathrm{holim}_{\rightarrow}(\mathcal{F})^{\mathrm{op}} \rightarrow \mathrm{Sing}_\bullet(|S|)$. Using Example 5.3.2.5 (and Example 5.2.6.4), we can identify $\mathrm{holim}_{\rightarrow}(\mathcal{F})^{\mathrm{op}}$ with the nerve of the category of simplices Δ_S (see Construction 1.1.3.9). We complete the proof by taking v to be the composition

$$N_\bullet(\Delta_S) \xrightarrow{\psi} S \xrightarrow{u} \mathrm{Sing}_\bullet(|S|),$$

where u is the weak homotopy equivalence of Theorem 3.6.4.1 and $\psi : N_\bullet(\Delta_S) \rightarrow S$ is the comparison map of Construction 3.3.3.10. By virtue of Variant 6.3.6.4, the morphism ψ is universally localizing, and is therefore also a weak homotopy equivalence (Remark 6.3.5.6). $\square$

Proof of Proposition 10.2.1.1. Let $\mathcal{T}$ be the ∞ -category $N_{\bullet}^{\text{hc}}(\text{Top})$, and let $\mathcal{T}_0 \subseteq \mathcal{T}$ be the full subcategory spanned by those topological spaces which have the homotopy type of a CW complex. It follows from Example 6.2.2.14 that $\mathcal{T}_0$ is a coreflective subcategory of $\mathcal{T}$; in particular, the inclusion map $\mathcal{T}_0 \hookrightarrow \mathcal{T}$ preserves colimits (Variant 7.1.4.26). It will therefore suffice to show that for every simplicial set S , the geometric realization $|S|$ is a colimit of the diagram $N_{\bullet}(\Delta^{\text{op}}) \xrightarrow{S} N_{\bullet}(\text{Set}) \subset \mathcal{T}_0$. This is a reformulation of Variant 10.2.1.2, since the functor $X \mapsto \text{Sing}_{\bullet}(X)$ determines an equivalence of ∞ -categories $\mathcal{T}_0 \rightarrow \mathcal{S}$ (Remark 5.5.1.9). $\square$

Motivated by Proposition 10.2.1.1, we introduce the following terminology:

- 04QT **Definition 10.2.1.3** (Geometric Realization). Let $X_{\bullet}$ be a simplicial object of an ∞ -category $\mathcal{C}$. We will say that an object $X \in \mathcal{C}$ is a *geometric realization of $X_{\bullet}$* if it is a colimit of the diagram $X_{\bullet} : N_{\bullet}(\Delta^{\text{op}}) \rightarrow \mathcal{C}$.
- 04QU **Warning 10.2.1.4.** Let $S = S_{\bullet}$ be a simplicial set. Proposition 10.2.1.1 asserts that the topological space $|S|$ introduced in §1.2.3 is a geometric realization of S (in the sense of Definition 10.2.1.3), provided that we regard S as a simplicial object of the ∞ -category $N_{\bullet}^{\text{hc}}(\text{Top})$ (by equipping each of the sets S_n with the discrete topology). Beware that $|S_{\bullet}|$ is usually *not* a geometric realization of S (in the sense of Definition 10.2.1.3) if we regard S as a simplicial object of the ∞ -category $N_{\bullet}(\text{Set})$. The latter is a colimit of the diagram $\Delta^{\text{op}} \xrightarrow{S} \text{Set}$, which identifies with the set of connected components $\pi_0(S)$ (see Remark 1.2.1.20), or equivalently with the set of path components of the topological space $|S|$ (see Corollary 1.2.3.19).
- 04QV **Notation 10.2.1.5.** Let $X_{\bullet}$ be a simplicial object of an ∞ -category $\mathcal{C}$. It follows from Proposition 7.1.1.12 that, if $X_{\bullet}$ admits a geometric realization X , then the isomorphism class of X is uniquely determined. To emphasize this, we will often denote X by $|X_{\bullet}|$ and refer to it as *the* geometric realization of $X_{\bullet}$. Beware that, in the case where $\mathcal{C}$ is (the nerve of) the category of sets, this is incompatible with the convention of Notation 1.2.3.3 (see Warning 10.2.1.4).
- 04QW **Exercise 10.2.1.6.** Let $X_{\bullet}$ be a simplicial object of an ordinary category $\mathcal{C}$. Show that an object $X \in \mathcal{C}$ is a geometric realization of $X_{\bullet}$ (in the ∞ -category $N_{\bullet}(\mathcal{C})$) if and only if it is a coequalizer of the face operators $d_0^1, d_1^1 : X_1 \rightrightarrows X_0$. For a slightly more general statement, see Corollary 10.2.2.12.
- 04QX **Example 10.2.1.7** (Simplicial Abelian Groups). Let Ab denote the category of abelian groups. By virtue of the Dold-Kan correspondence (Theorem 2.5.6.1), there is an equivalence of categories $\text{Fun}(\Delta^{\text{op}}, \text{Ab}) \rightarrow \text{Ch}(\mathbf{Z})_{\geq 0}$, which carries each simplicial abelian group $A_{\bullet}$ to its normalized Moore complex

$$N_*(A) = (\cdots \rightarrow N_2(A) \xrightarrow{\partial} N_1(A) \xrightarrow{\partial} N_0(A)).$$

Under this equivalence, the coequalizer of the pair of face operators $d_0^1, d_1^1 : A_1 \rightrightarrows A_0$ can be identified with the 0th homology group $H_0(N_*(A)) = \text{coker}(\partial : N_1(A) \rightarrow N_0(A))$, or alternatively with the homotopy group $\pi_0(A_\bullet)$ (see Exercise 3.2.2.22). Using Exercise 10.2.1.6 we see that the $\pi_0(A)$ can be regarded as a geometric realization of $A_\bullet$ in the category of abelian groups. In particular, the forgetful functor $\text{Ab} \rightarrow \text{Set}$ commutes with the formation of geometric realizations (this is a special case of a more general phenomenon, which we will return to in §[?]).

Remark 10.2.1.8. Let $X_\bullet$ be a simplicial object of a category $\mathcal{C}$. It follows from Exercise 10.2.1.6 that a geometric realization of $X_\bullet$ (if it exists) depends only on the pair of face operators $d_0^1, d_1^1 : X_1 \rightrightarrows X_0$. Beware that, in the ∞ -categorical setting, this is generally not true: the geometric realization $|X_\bullet|$ is sensitive to information about the *entire* simplicial object $X_\bullet$. 04QY

Variant 10.2.1.9. Let $X^\bullet$ be a cosimplicial object of an ∞ -category $\mathcal{C}$. We will say that an object $X \in \mathcal{C}$ is a *totalization of $X^\bullet$* if it is a limit of the diagram $X^\bullet : N_\bullet(\Delta) \rightarrow \mathcal{C}$. If this condition is satisfied, then X is uniquely determined up to isomorphism. To emphasize this, we will often denote X by $\text{Tot}(X^\bullet)$ and refer to it as *the* totalization of $X^\bullet$. 04QZ

For many applications, the language of Definition 10.2.1.3 is insufficiently precise. Given a simplicial object $X_\bullet$ of an ∞ -category $\mathcal{C}$, we would like to view its geometric realization $|X_\bullet|$ not abstractly as an object of $\mathcal{C}$, but as an object of the coslice ∞ -category $\mathcal{C}_{X_\bullet/}$. For this purpose, it will be convenient to introduce some additional terminology.

Definition 10.2.1.10 (The Augmented Simplex Category). For each integer $n \geq -1$, let $[n]$ denote the linearly ordered set $\{0 < 1 < \cdots < n\}$, so that $[-1]$ is the empty set. We let Δ_+ denote the category whose objects are the linearly ordered sets $\{[n]\}_{n \geq -1}$, and whose morphisms are nondecreasing functions. We will refer to Δ_+ as the *augmented simplex category*. 04R0

Remark 10.2.1.11. The augmented simplex category Δ_+ of Definition 10.2.1.10 contains the simplex category Δ of Definition 1.1.0.2 as a full subcategory (spanned by the objects $[n]$ for $n \geq 0$). Moreover, Δ_+ can be obtained from Δ by adjoining a single object $[-1]$, which is an initial object satisfying $\text{Hom}_{\Delta_+}([n], [-1]) = \emptyset$ for $n \geq 0$. In other words, Δ_+ can be identified with the left cone $\Delta^\triangleleft$ (see Example 4.3.2.5). 04R1

Definition 10.2.1.12 (Augmented Simplicial Objects). Let $\mathcal{C}$ be an ∞ -category. An *augmented simplicial object of $\mathcal{C}$* is a functor from the ∞ -category $N_\bullet(\Delta_+^{\text{op}})$ to $\mathcal{C}$. An *augmented cosimplicial object* is a functor from the ∞ -category $N_\bullet(\Delta_+)$ to $\mathcal{C}$. 04R2

Notation 10.2.1.13. Let $\mathcal{C}$ be an ∞ -category. We will often use the notation $X_\bullet$ to indicate an augmented simplicial object of $\mathcal{C}$. In this case, we write X_n for the value of the functor $X_\bullet$. 04R3

on the object $[n] \in \Delta_+^{\text{op}}$. Similarly, we often use the expression $X^\bullet$ to indicate an augmented cosimplicial object of $\mathcal{C}$, and X^n for its value on the object $[n] \in \Delta_+$.

04R4 **Remark 10.2.1.14.** Let $\mathcal{C}$ be an ∞ -category. Every augmented simplicial object of $\mathcal{C}$ determines a simplicial object of $\mathcal{C}$, by restriction along the inclusion of full subcategories $\Delta^{\text{op}} \hookrightarrow \Delta_+^{\text{op}}$. For this reason, we will sometimes use the notation $\overline{X}_\bullet$ to indicate an augmented simplicial object of $\mathcal{C}$, to distinguish it from the underlying simplicial object $X_\bullet = \overline{X}_\bullet|_{N_\bullet(\Delta^{\text{op}})}$.

04R5 **Remark 10.2.1.15.** Let $\mathcal{C}$ be an ∞ -category containing an object X . By virtue of Remark 10.2.1.11, the following data are equivalent:

- Augmented simplicial objects $N_\bullet(\Delta_+^{\text{op}}) \rightarrow \mathcal{C}$ carrying the object $[-1]$ to X .
- Simplicial objects of the slice ∞ -category $\mathcal{C}_{/X}$.

We will often invoke this equivalence implicitly, using the notation $X_\bullet$ to indicate both an augmented simplicial object of $\mathcal{C}$ (satisfying $X_{-1} = X$) and the associated simplicial object of $\mathcal{C}_{/X}$.

04R6 **Definition 10.2.1.16.** Let $\mathcal{C}$ be an ∞ -category containing an object X , let $\overline{X}_\bullet$ be an augmented simplicial object of $\mathcal{C}$ satisfying $\overline{X}_{-1} = X$, and let $X_\bullet = \overline{X}_\bullet|_{N_\bullet(\Delta^{\text{op}})}$ denote its underlying simplicial object. We will say that $\overline{X}_\bullet$ *exhibits X as a geometric realization of $X_\bullet$* if it is a colimit diagram in the ∞ -category $\mathcal{C}$, in the sense of Variant 7.1.3.5.

Similarly, if $\overline{X}^\bullet$ is an augmented cosimplicial object of $\mathcal{C}$ satisfying $\overline{X}^{-1} = X$ and $X^\bullet = \overline{X}^\bullet|_{N_\bullet(\Delta)}$ is the underlying cosimplicial object, we say that $\overline{X}^\bullet$ *exhibits X as a totalization of $X^\bullet$* if it is a limit diagram in the ∞ -category $\mathcal{C}$, in the sense of Definition 7.1.3.4.

04R7 **Remark 10.2.1.17.** Let $\mathcal{C}$ be an ∞ -category, let $X_\bullet$ be a simplicial object of $\mathcal{C}$, and let X be an object of $\mathcal{C}$. Then X is a geometric realization of $X_\bullet$ (in the sense of Definition 10.2.1.3) if and only if there exists an augmented simplicial object $\overline{X}_\bullet$ which exhibits X as a geometric realization of $X_\bullet$ (in the sense of Definition 10.2.1.16). See Remark 7.1.3.7.

10.2.2 Semisimplicial Objects

04R8 Let Δ denote the simplex category (Definition 1.1.0.2), and let Δ_{inj} denote the subcategory of Δ whose morphisms are strictly increasing functions $[m] \hookrightarrow [n]$ (Definition 1.1.1.2). It will often be useful to consider the following variant of Definition 10.2.0.1:

04R9 **Definition 10.2.2.1** (Semisimplicial Objects). Let $\mathcal{C}$ be an ∞ -category. A *semisimplicial object of $\mathcal{C}$* is a functor $N_\bullet(\Delta_{\text{inj}}^{\text{op}}) \rightarrow \mathcal{C}$. A *cosemisimplicial object of $\mathcal{C}$* is a functor $N_\bullet(\Delta_{\text{inj}}) \rightarrow \mathcal{C}$.

Notation 10.2.2.2. Let $\mathcal{C}$ be an ∞ -category. We will often use the notation $X_\bullet$ to indicate a semisimplicial object of $\mathcal{C}$. In this case, we write X_n for the value of the functor $X_\bullet$ on the object $[n] \in \Delta_{\text{inj}}^{\text{op}}$. Similarly, we often use an expression like $X^\bullet$ to indicate a cosemisimplicial object of $\mathcal{C}$, and X^n for its value on the object $[n] \in \Delta_{\text{inj}}$. 04RA

Example 10.2.2.3. Let $\mathcal{C}$ be a category. Then (co)semisimplicial objects of the ∞ -category $\mathbf{N}_\bullet(\mathcal{C})$ (in the sense of Definition 10.2.2.1) can be identified with (co)semisimplicial objects of $\mathcal{C}$ (in the sense of Definition 1.1.1.2). 04RB

Example 10.2.2.4. Let $\mathcal{C}$ be an ∞ -category and let $X_\bullet$ be a simplicial object of $\mathcal{C}$. The composite functor 04RC

$$\mathbf{N}_\bullet(\Delta_{\text{inj}}^{\text{op}}) \subset \mathbf{N}_\bullet(\Delta^{\text{op}}) \xrightarrow{X_\bullet} \mathcal{C}$$

is a semisimplicial object of $\mathcal{C}$, which we will refer to as the *underlying semisimplicial object of $X_\bullet$* . We will often abuse notation by identifying $X_\bullet$ with its underlying semisimplicial object. Similarly, every cosimplicial object $X^\bullet$ of $\mathcal{C}$ has an underlying cosemisimplicial object, given by the composition

$$\mathbf{N}_\bullet(\Delta_{\text{inj}}) \subset \mathbf{N}_\bullet(\Delta) \xrightarrow{X^\bullet} \mathcal{C}.$$

Remark 10.2.2.5 (Face Operators). Let $X_\bullet$ be a semisimplicial object of an ∞ -category. For every pair of integers $0 \leq i \leq n$ with $n > 0$, we let $d_i^n : X_n \rightarrow X_{n-1}$ denote the morphism induced by the inclusion of linearly ordered sets $\delta_n^i : [n-1] \hookrightarrow [n]$ introduced in Construction 1.1.1.4. We will refer to d_i^n as the *i th face operator* of the semisimplicial object $X_\bullet$. 04RD

The utility of Definition 10.2.2.1 stems in part from the fact that, for many purposes, passage from simplicial to semisimplicial objects does not lose very much information.

Proposition 10.2.2.6. *The inclusion $\Delta_{\text{inj}} \subset \Delta$ determines a left cofinal functor of ∞ -categories $\mathbf{N}_\bullet(\Delta_{\text{inj}}) \hookrightarrow \mathbf{N}_\bullet(\Delta)$.* 04RE

Proof. By virtue of Theorem 7.2.3.1, it will suffice to show that for every integer $n \geq 0$, the category $\mathcal{C} = \Delta_{\text{inj}} \times_\Delta \Delta_{/[n]}$ has weakly contractible nerve. Let $C_0 \in \mathcal{C}$ denote the object corresponding to the inclusion map $[0] \simeq \{n\} \hookrightarrow [n]$. For every object $C \in \mathcal{C}$, given by a nondecreasing function $\alpha : [m] \rightarrow [n]$, we let $F(C) \in \mathcal{C}$ denote the object given by the nondecreasing function $\alpha^+ : [m+1] \rightarrow [n]$ given by the formula

$$\alpha^+(i) = \begin{cases} \alpha(i) & \text{if } 0 \leq i \leq m \\ n & \text{if } i = m+1. \end{cases}$$

Note that we have canonical maps $C \xrightarrow{\beta_-} F(C) \xleftarrow{\beta_+} C_0$, given by the inclusions

$$\{0 < 1 < \cdots < m\} \hookrightarrow \{0 < 1 < \cdots < m+1\} \hookleftarrow \{m+1\}.$$

These morphisms depend functorially on C , and therefore furnish natural transformations of functors $\text{id}_C \rightarrow F \leftarrow \underline{C}_0$, where $\underline{C}_0 : C \rightarrow C$ denotes the constant functor taking the value C_0 . It follows that the identity morphism of the simplicial set $N_\bullet(C)$ is homotopic to the constant morphism $N_\bullet(C) \rightarrow \{C_0\} \hookrightarrow N_\bullet(C)$, so that the simplicial set $N_\bullet(C)$ is contractible (and, in particular, it is weakly contractible). $\square$

04RF Corollary 10.2.2.7. *Let C be an ∞ -category and let $X_\bullet$ be a simplicial object of C . Then an object $X \in C$ is a geometric realization of $X_\bullet$ (in the sense of Definition 10.2.1.3) if and only if it is a colimit of the underlying diagram $N_\bullet(\Delta_{\text{inj}}^{\text{op}}) \subset N_\bullet(\Delta^{\text{op}}) \xrightarrow{X_\bullet} C$.*

Proof. Combine Proposition 10.2.2.6 with Corollary 7.2.2.11. $\square$

04RG Example 10.2.2.8. Let S be a simplicial set and let $|S|$ denote its geometric realization as a topological space (Definition 1.2.3.1). Combining Proposition 10.2.1.1 with Corollary 10.2.2.7, we deduce that the homotopy type of the topological space $|S|$ depends only on the underlying semisimplicial set of S . Compare with Corollary 3.4.5.5.

Motivated by Corollary 10.2.2.7, we introduce the following terminology:

04RH Definition 10.2.2.9. Let C be an ∞ -category and let $X_\bullet$ be a semisimplicial object of C . We say that an object $X \in C$ is a *geometric realization of $X_\bullet$* if it is a colimit of the diagram $X_\bullet : N_\bullet(\Delta_{\text{inj}}^{\text{op}}) \rightarrow C$. If $X^\bullet$ is a cosemisimplicial object of C , we say that an object $X \in C$ is a *totalization of $X^\bullet$* if it is a limit of the diagram $X^\bullet : N_\bullet(\Delta_{\text{inj}}) \rightarrow C$.

04RJ Remark 10.2.2.10. Let $X_\bullet$ be a simplicial object of an ∞ -category C . Corollary 10.2.2.7 asserts that an object $X \in C$ is a geometric realization of $X_\bullet$ (in the sense of Definition 10.2.1.3) if and only if it is a geometric realization of the underlying semisimplicial object of $X_\bullet$ (in the sense of Definition 10.2.2.9). In particular, $X_\bullet$ admits a geometric realization if and only if its underlying semisimplicial object admits a geometric realization.

In the setting of classical category theory, the notion of geometric realization can be made more concrete.

04RK Proposition 10.2.2.11. *Let C be a category, let Y be an object of C , and let $\underline{Y}$ denote the constant semisimplicial object of C taking the value Y . For every semisimplicial object $X_\bullet$ of C , the evaluation map*

$$\text{Hom}_{\text{Fun}(\Delta_{\text{inj}}^{\text{op}}, C)}(X_\bullet, \underline{Y}) \rightarrow \text{Hom}_C(X_0, Y)$$

is a monomorphism, whose image is the set of morphisms $\epsilon : X_0 \rightarrow Y$ which satisfy the following condition:

() The face operators $d_0^1, d_1^1 : X_1 \rightarrow X_0$ of the simplicial object $X_\bullet$ satisfy $\epsilon \circ d_0^1 = \epsilon \circ d_1^1$.*

Proof. For every integer $n \geq 0$, let ι_n denote the inclusion map $[0] = \{0\} \hookrightarrow \{0 < 1 < \cdots < n\} = [n]$ and write $\iota_n^* : X_n \rightarrow X_0$ for the associated morphism of $\mathcal{C}$. If $f_\bullet : X_\bullet \rightarrow \underline{Y}$ is a morphism of semisimplicial objects, then we must have $f_n = f_0 \circ \iota_n^*$ for each $n \geq 0$; in particular, $f_\bullet$ is uniquely determined by the morphism $\epsilon = f_0$. To complete the proof, it will suffice to show that if a morphism $\epsilon : X_0 \rightarrow Y$ satisfies condition (*), then the collection $\{(\epsilon \circ \iota_n^*) : X_n \rightarrow Y\}_{n \geq 0}$ determines a morphism of semisimplicial objects from $X_\bullet$ to $\underline{Y}$ (the converse follows immediately from the definitions). Fix a strictly increasing function $\alpha : [m] \hookrightarrow [n]$; we wish to show that the diagram

$$\begin{array}{ccc} X_n & \xrightarrow{\iota_n^*} & X_0 \\ \downarrow \alpha^* & & \downarrow \epsilon \\ X_m & \xrightarrow{\epsilon \circ \iota_m^*} & Y \end{array} \quad \begin{array}{l} \text{04RL} \\ (10.1) \end{array}$$

commutes. If $\alpha(0) = 0$, then $\iota_n = \alpha \circ \iota_m$. It follows that $\iota_n^* = \iota_m^* \circ \alpha^*$, and the desired result follows by composing with ϵ on both sides. We may therefore assume without loss of generality that $\alpha(0) > 0$. Let $\beta : [1] \hookrightarrow [n]$ be the strictly increasing function given by $\beta(0) = 0$ and $\beta(1) = \alpha(0)$. Then (10.1) can be identified with the outer rectangle of the diagram

$$\begin{array}{ccccc} X_n & \xrightarrow{\beta^*} & X_1 & \xrightarrow{d_1^1} & X_0 \\ \downarrow \alpha^* & & \downarrow d_0^1 & & \downarrow \epsilon \\ X_m & \xrightarrow{\iota_m^*} & X_0 & \xrightarrow{\epsilon} & Y, \end{array}$$

where the left square commutes by the naturality of the construction $[k] \mapsto X_k$, and the right square commutes by virtue of assumption (*). $\square$

Corollary 10.2.2.12. *Let $X_\bullet$ be a semisimplicial object of a category $\mathcal{C}$. Then an object $X \in \mathcal{C}$ is a geometric realization of $X_\bullet$ (in the ∞ -category $\mathbf{N}_\bullet(\mathcal{C})$) if and only if it is a coequalizer of the face operators $d_0^1, d_1^1 : X_1 \rightrightarrows X_0$.* 04RM

For some applications, we will need more precise language for discussing geometric realizations of semisimplicial objects.

Notation 10.2.2.13. Let Δ_+ be the augmented simplex category (Definition 10.2.1.10). We let $\Delta_{\text{inj},+}$ denote the (non-full) subcategory of Δ_+ whose morphisms are strictly increasing functions $[m] \hookrightarrow [n]$. Note that $\Delta_{\text{inj},+}$ can be obtained from the category Δ_{inj} by adjoining an initial object $[-1]$ satisfying $\text{Hom}_{\Delta_{+, \text{inj}}}([n], [-1]) = \emptyset$ for $n \geq 0$. Consequently, $\Delta_{\text{inj},+}$ can be identified with the left cone $\Delta_{\text{inj}}^\triangleleft$ (see Example 4.3.2.5). 04RN

04RP **Proposition 10.2.2.14.** *The diagram of ∞ -categories*

$$\begin{array}{ccc} N_{\bullet}(\Delta_{\text{inj}}) & \longrightarrow & N_{\bullet}(\Delta) \\ \downarrow & & \downarrow \\ N_{\bullet}(\Delta_{\text{inj},+}) & \longrightarrow & N_{\bullet}(\Delta_+) \end{array}$$

is a categorical pushout square.

Proof. By virtue of Proposition 7.2.2.1, this is a reformulation of Proposition 10.2.2.6. $\square$

04RQ **Definition 10.2.2.15** (Augmented Semisimplicial Objects). Let $\mathcal{C}$ be an ∞ -category. An *augmented semisimplicial object* of $\mathcal{C}$ is a functor from the ∞ -category $N_{\bullet}(\Delta_{\text{inj},+}^{\text{op}})$ to $\mathcal{C}$. An *augmented cosemisimplicial object* is a functor from the ∞ -category $N_{\bullet}(\Delta_+)$ to $\mathcal{C}$.

04RR **Notation 10.2.2.16.** Let $\mathcal{C}$ be an ∞ -category. We will often use the notation $X_{\bullet}$ to indicate an augmented semisimplicial object of $\mathcal{C}$. In this case, we write X_n for the value of the functor $X_{\bullet}$ on the object $[n] \in \Delta_{\text{inj},+}^{\text{op}}$. Similarly, we often use the expression $X^{\bullet}$ to indicate an augmented cosimplicial object of $\mathcal{C}$, and X^n for its value on the object $[n] \in \Delta_{\text{inj},+}$.

04RS **Remark 10.2.2.17.** Let $\mathcal{C}$ be an ∞ -category. Every augmented semisimplicial object of $\mathcal{C}$ determines a semisimplicial object of $\mathcal{C}$, by restriction along the inclusion of full subcategories $\Delta_{\text{inj}}^{\text{op}} \hookrightarrow \Delta_{\text{inj},+}^{\text{op}}$. For this reason, we will sometimes use the notation $\overline{X}_{\bullet}$ to indicate an augmented semisimplicial object of $\mathcal{C}$, to distinguish it from the underlying simplicial object $X_{\bullet} = \overline{X}_{\bullet}|_{N_{\bullet}(\Delta_{\text{inj}}^{\text{op}})}$.

04RT **Remark 10.2.2.18.** Let $\mathcal{C}$ be an ∞ -category. It follows from Proposition 10.2.2.14 that the diagram of ∞ -categories

$$\begin{array}{ccc} \text{Fun}(N_{\bullet}(\Delta_+^{\text{op}}), \mathcal{C}) & \longrightarrow & \text{Fun}(N_{\bullet}(\Delta^{\text{op}}), \mathcal{C}) \\ \downarrow & & \downarrow \\ \text{Fun}(N_{\bullet}(\Delta_{\text{inj},+}^{\text{op}}), \mathcal{C}) & \longrightarrow & \text{Fun}(N_{\bullet}(\Delta_{\text{inj}}^{\text{op}}), \mathcal{C}) \end{array}$$

is a categorical pullback square. In particular, if $X_{\bullet}$ is a simplicial object of $\mathcal{C}$, then the datum of an augmentation of $X_{\bullet}$ is equivalent to the datum of an augmentation on the underlying semisimplicial object of $X_{\bullet}$.

Remark 10.2.2.19 (Face Operators). For every pair of integers $0 \leq i \leq n$, there is a unique 04RU increasing function $\delta_n^i : [n-1] \hookrightarrow [n]$ whose image is the set $[n] \setminus \{i\}$, given concretely by the formula

$$\delta_n^i(j) = \begin{cases} j & \text{if } j < i \\ j+1 & \text{if } j \geq i. \end{cases}$$

If $X_\bullet$ is an augmented semisimplicial object of an ∞ -category $\mathcal{C}$, then evaluation on the morphism δ_n^i determines a map $d_i^n : X_n \rightarrow X_{n-1}$, which we will refer to as the *ith face operator* for the augmented semisimplicial object $X_\bullet$. If $n > 0$, this recover the face operators for the underlying semisimplicial object of $X_\bullet$ (Remark 10.2.2.5). In the case $n = 0$, we obtain a new operator $d_0^0 : X_0 \rightarrow X_{-1}$.

Remark 10.2.2.20. Let $\mathcal{C}$ be an ∞ -category containing an object X . By virtue of Remark 04RV 10.2.1.11, the following data are equivalent:

- Augmented semisimplicial objects $N_\bullet(\Delta_+^{\text{op}}) \rightarrow \mathcal{C}$ carrying the object $[-1]$ to X .
- Semisimplicial objects of the slice ∞ -category $\mathcal{C}_{/X}$.

We will often invoke this equivalence implicitly, using the notation $X_\bullet$ to indicate both an augmented simplicial object of $\mathcal{C}$ (satisfying $X_{-1} = X$) and the associated simplicial object of $\mathcal{C}_{/X}$.

Remark 10.2.2.21 (Augmented Moore Complexes). Let $A_\bullet$ be an augmented semisimplicial 04RW object of the category of abelian groups. For each $n \geq 0$, let $\partial : A_n \rightarrow A_{n-1}$ denote the group homomorphism given by the alternating sum

$$\partial(\sigma) = \sum_{i=0}^n (-1)^i d_i^n(\sigma).$$

The diagram

$$\cdots \rightarrow A_2 \xrightarrow{\partial} A_1 \xrightarrow{\partial} A_0 \xrightarrow{\partial} A_{-1}$$

is a chain complex of abelian groups which we will denote by $C_*^{\text{aug}}(A)$ and refer to as the *augmented Moore complex of $A_\bullet$* . Note that, when restricted to nonnegative degrees, this recovers the Moore complex of the underlying semisimplicial abelian group (see Construction 2.5.5.1).

Variante 10.2.2.22. Let $A_\bullet$ be an augmented simplicial object of the category of abelian 04RX groups. Let us abuse notation by identifying $A_\bullet$ with the underlying simplicial abelian group, and let

$$D_*(A) \subseteq C_*(A) \subseteq C_*^{\text{aug}}(A)$$

be the subcomplex generated by the images of the degeneracy operators (see Proposition 2.5.5.6). We let $N_*^{\text{aug}}(A)$ denote the quotient complex $C_*^{\text{aug}}(A)/D_*(A)$, which we will refer to as the *normalized augmented Moore complex* of $A_\bullet$. Note that, when restricted to nonnegative degrees, this recovers the normalized Moore complex of the underlying simplicial abelian group (Construction 2.5.5.7).

04RY Definition 10.2.2.23. Let $\mathcal{C}$ be an ∞ -category containing an object X , let $\overline{X}_\bullet$ be an augmented semisimplicial object of $\mathcal{C}$ satisfying $\overline{X}_{-1} = X$, and let $X_\bullet = \underline{X}_\bullet|_{N_\bullet(\Delta_{\text{inj}}^{\text{op}})}$ denote its underlying semisimplicial object. We will say that $\overline{X}_\bullet$ *exhibits X as a geometric realization of $X_\bullet$* if it is a colimit diagram in the ∞ -category $\mathcal{C}$, in the sense of Variant 7.1.3.5.

Similarly, if $\overline{X}^\bullet$ is an augmented cosemisimplicial object of $\mathcal{C}$ satisfying $\overline{X}^{-1} = X$ and $X^\bullet = \overline{X}^\bullet|_{N_\bullet(\Delta_{\text{inj}})}$ is the underlying cosemisimplicial object, we say that $\overline{X}^\bullet$ *exhibits X as a totalization of $X^\bullet$* if it is a limit diagram in the ∞ -category $\mathcal{C}$, in the sense of Definition 7.1.3.4.

04RZ Remark 10.2.2.24. Let $\mathcal{C}$ be an ∞ -category, let $X_\bullet$ be a semisimplicial object of $\mathcal{C}$, and let X be an object of $\mathcal{C}$. Then X is a geometric realization of $X_\bullet$ (in the sense of Definition 10.2.2.9) if and only if there exists an augmented semisimplicial object $\overline{X}_\bullet$ which exhibits X as a geometric realization of $X_\bullet$ (in the sense of Definition 10.2.2.23). See Remark 7.1.3.7.

By virtue of Example 4.3.2.15, we can formulate Proposition 10.2.2.11 as follows:

04S0 Proposition 10.2.2.25. *Let $\mathcal{C}$ be a category, let X be an object of $\mathcal{C}$, and let $X_\bullet$ be a semisimplicial object of $\mathcal{C}$. The following data are equivalent:*

- *Extensions of $X_\bullet$ to an augmented semisimplicial object $\overline{X}_\bullet$ satisfying $\overline{X}_{-1} = X$.*
- *Morphisms $\epsilon : X_0 \rightarrow X$ satisfying $\epsilon \circ d_0^1 = \epsilon \circ d_1^1$, where $d_0^1, d_1^1 : X_1 \rightrightarrows X_0$ are the face operators of the semisimplicial object $X_\bullet$.*

Here the equivalence is implemented by taking ϵ to be the face operator $d_0^0 : X_0 \rightarrow X_{-1}$ of Remark 10.2.2.19.

04S1 Remark 10.2.2.26. In the situation of Proposition 10.2.2.25, the augmented semisimplicial object $\overline{X}_\bullet$ exhibits X as a geometric realization of $X_\bullet$ (in the sense of Definition 10.2.1.16) if and only if the morphism ϵ exhibits X as a coequalizer of the face operators $d_0^1, d_1^1 : X_1 \rightrightarrows X_0$.

Combining Propositions 10.2.2.25 and 1.1.1.9, we obtain an explicit characterization of augmented semisimplicial objects of ordinary categories:

04S2 Corollary 10.2.2.27. *Let $\mathcal{C}$ be a category and let $\{X_n\}_{n \geq -1}$ be a sequence of objects of $\mathcal{C}$. Then a system of morphisms $\{d_i^n : X_n \rightarrow X_{n-1}\}_{0 \leq i \leq n}$ arise as the face operators of an augmented semisimplicial object $X_\bullet$ of $\mathcal{C}$ if and only if they satisfy the following condition:*

(*) For all integers $n > 0$ and $0 \leq i < j \leq n$, we have an equality $d_i^{n-1} \circ d_j^n = d_{j-1}^{n-1} \circ d_i^n$ (as morphisms from X_n to X_{n-2}).

If this condition is satisfied, then the augmented semisimplicial object $X_\bullet$ is uniquely determined.

Variant 10.2.2.28. Let $\mathcal{C}$ be a category and let $\{X_n\}_{n \geq -1}$ be a sequence of objects of $\mathcal{C}$. 04S3
Then morphisms

$$\{d_i^n : X_n \rightarrow X_{n-1}\}_{0 \leq i \leq n} \quad \{s_i^n : X_n \rightarrow X_{n+1}\}_{0 \leq i \leq n}$$

are the face and degeneracy operators for an augmented simplicial object $X_\bullet$ of $\mathcal{C}$ if and only if they satisfy the following conditions:

- (1) For all integers $n > 0$ and $0 \leq i < j \leq n$, we have an equality $d_i^{n-1} \circ d_j^n = d_{j-1}^{n-1} \circ d_i^n$ (as morphisms from X_n to X_{n-2}).
- (2) For all integers $0 \leq i \leq j \leq n$, we have an equality $s_i^{n+1} \circ s_j^n = s_{j+1}^{n+1} \circ s_i^n$ (as morphisms from X_n to X_{n+2}).
- (3) For all integers $0 \leq i, j \leq n$, we have an equality

$$d_i^{n+1} \circ s_j^n = \begin{cases} s_{j-1}^{n-1} \circ d_i^n & \text{if } i < j \\ \text{id}_{X_n} & \text{if } i = j \text{ or } i = j + 1 \\ s_j^{n-1} \circ d_{i-1}^n & \text{if } i > j + 1 \end{cases}$$

(as morphisms from X_n to X_n).

If these conditions are satisfied, then the augmented simplicial object $X_\bullet$ is uniquely determined.

Proof. Combine Proposition 1.1.2.14, Remark 10.2.2.18, and Corollary 10.2.2.27. $\square$

We close this section with a few remarks concerning the relationship between simplicial and semisimplicial objects.

Proposition 10.2.2.29. Let $\mathcal{C}$ be an ∞ -category which admits finite coproducts and let $X_\bullet$ 04S4
be a semisimplicial object of $\mathcal{C}$. Then there exists a simplicial object $X_\bullet^+$ of $\mathcal{C}$ and a natural transformation of semisimplicial objects $f_\bullet : X_\bullet \rightarrow X_\bullet^+$ which exhibits $X_\bullet^+$ as a left Kan extension of $X_\bullet$ along the inclusion map $N_\bullet(\Delta_{\text{inj}}^{\text{op}}) \subseteq N_\bullet(\Delta^{\text{op}})$.

Proof. We will show that $X_\bullet$ satisfies the criterion of Proposition 7.3.5.1. Fix an object $[n] \in \Delta$, let $\mathcal{E}$ denote the fiber product $\Delta_{\text{inj}} \times_\Delta \Delta_{[n]}$, and let F denote the composite map

$$N_\bullet(\mathcal{E}^{\text{op}}) \rightarrow N_\bullet(\Delta_{\text{inj}}^{\text{op}}) \xrightarrow{X_\bullet} \mathcal{C}.$$

We wish to show that F admits a colimit in $\mathcal{C}$.

By definition, objects of the category $\mathcal{E}$ can be identified with pairs $([m], \alpha)$, where $[m]$ is an object of Δ_{inj} and $\alpha : [n] \rightarrow [m]$ is a nondecreasing function. Let $\mathcal{E}_0 \subseteq \mathcal{E}$ denote the full subcategory spanned by those objects $([m], \alpha)$ where α is a surjection. Note that any morphism $\alpha : [n] \rightarrow [m]$ in Δ factors uniquely as a composition $[n] \xrightarrow{\alpha'} [m'] \xrightarrow{\beta} [m]$, where α' is a surjection and β is an injection. The pair $([m'], \alpha')$ is then an object of the subcategory $\mathcal{E}_0$, and the morphism $\beta : ([m'], \alpha') \rightarrow ([m], \alpha)$ exhibits $([m'], \alpha')$ as a $\mathcal{E}_0$ -coreflection of $([m], \alpha)$ (see Definition 6.2.2.6). It follows that the inclusion map $N_\bullet(\mathcal{E}_0^{\text{op}}) \hookrightarrow N_\bullet(\mathcal{E}^{\text{op}})$ is right cofinal (Corollary 7.2.2.7). Consequently, to show that F admits a colimit in $\mathcal{C}$, it will suffice to show that the restriction $F|_{N_\bullet(\mathcal{E}_0^{\text{op}})}$ admits a colimit in $\mathcal{C}$ (Corollary 7.2.2.10). Since the category $\mathcal{E}_0$ has finitely many objects and only identity morphisms, this follows from our assumption that $\mathcal{C}$ admits finite coproducts. $\square$

04S5 Remark 10.2.2.30. Let $\mathcal{C}$ be an ∞ -category, let $Y_\bullet$ be a simplicial object of $\mathcal{C}$, and suppose we are given a morphism $f_\bullet : X_\bullet \rightarrow Y_\bullet$ of semisimplicial objects of $\mathcal{C}$. It follows from the proof of Proposition 10.2.2.29 that $f_\bullet$ exhibits $Y_\bullet$ as a left Kan extension of $X_\bullet$ along the inclusion map $N_\bullet(\Delta_{\text{inj}}^{\text{op}}) \subseteq N_\bullet(\Delta^{\text{op}})$ if and only if, for every integer $n \geq 0$, the following condition is satisfied:

($*_n$) Let E be the collection of all surjections $\alpha : [n] \twoheadrightarrow [m]$ in the category Δ . For each $\alpha \in E$, let $g_\alpha : X_m \rightarrow Y_n$ be a composition of $f_m : X_m \rightarrow Y_m$ with the morphism $\alpha^* : Y_m \rightarrow Y_n$. Then the collection $\{g_\alpha\}_{\alpha \in E}$ exhibit Y_n as a coproduct of the collection of objects $\{X_m\}_{(\alpha : [n] \twoheadrightarrow [m]) \in E}$.

Compare with Construction 3.3.1.6.

10.2.3 Skeletal Simplicial Objects

05G3 Recall that every set S can be regarded as a simplicial set, by identifying it with the constant functor

$$\underline{S} : \Delta^{\text{op}} \rightarrow \{S\} \hookrightarrow \text{Set}.$$

This construction has a counterpart in an ∞ -category:

05G4 Definition 10.2.3.1. Let $\mathcal{C}$ be an ∞ -category. For each object $C \in \mathcal{C}$, we let $\underline{C}$ denote the simplicial object of $\mathcal{C}$ given by the constant functor

$$N_\bullet(\Delta^{\text{op}}) \rightarrow \{C\} \hookrightarrow \mathcal{C}.$$

We say that a simplicial object $X_\bullet$ of $\mathcal{C}$ is *constant* if it is equal to $\underline{C}$, for some object $C \in \mathcal{C}$ (in this case, we must have $C = X_0$). We say that $X_\bullet$ is *essentially constant* if it is isomorphic to a constant simplicial object $\underline{C}$, for some $C \in \mathcal{C}$.

Proposition 10.2.3.2. *Let $\mathcal{C}$ be an ∞ -category and let $X_\bullet$ be a simplicial object of $\mathcal{C}$. The following conditions are equivalent:* 05G5

- (1) *The simplicial object $X_\bullet$ is essentially constant: that is, there exists an isomorphism of simplicial objects $\alpha : \underline{C} \rightarrow X_\bullet$ for some object $C \in \mathcal{C}$.*
- (2) *The functor $X_\bullet : N_\bullet(\Delta^{\text{op}}) \rightarrow \mathcal{C}$ carries each morphism in the category Δ^{op} to an isomorphism in the ∞ -category $\mathcal{C}$.*
- (3) *The functor $X_\bullet$ is left Kan extended from the full subcategory $\{[0]\} \subseteq N_\bullet(\Delta^{\text{op}})$.*
- (4) *For every simplicial object $Y_\bullet$ of $\mathcal{C}$, the restriction map*

$$\text{Hom}_{\text{Fun}(N_\bullet(\Delta^{\text{op}}), \mathcal{C})}(X_\bullet, Y_\bullet) \rightarrow \text{Hom}_{\mathcal{C}}(X_0, Y_0)$$

is a homotopy equivalence.

Proof. The equivalences (1) $\Leftrightarrow$ (2) $\Leftrightarrow$ (3) are special cases of Corollary 7.3.3.14, since $[0]$ is a final object of the category Δ . The equivalence (3) $\Leftrightarrow$ (4) follows from Corollary 7.3.6.13. $\square$

We now introduce a generalization of Definition 10.2.3.1.

Notation 10.2.3.3. Let Δ denote the simplex category (Definition 1.1.0.2). For every integer n , we let $\Delta^{\leq n}$ denote the full subcategory of Δ spanned by those objects $[m] = \{0 < 1 < \cdots < m\}$ where $0 \leq m \leq n$ (see Construction 1.1.3.9). 05G6

Definition 10.2.3.4. Let $\mathcal{C}$ be an ∞ -category and let n be an integer. We say that a simplicial object $X_\bullet$ of $\mathcal{C}$ is *n-skeletal* if the functor 05G7

$$N_\bullet(\Delta)^{\text{op}} \xrightarrow{X_\bullet} \mathcal{C}$$

is left Kan extended from the full subcategory $N_\bullet(\Delta^{\leq n})^{\text{op}} \subseteq N_\bullet(\Delta)^{\text{op}}$.

Example 10.2.3.5. Let $\mathcal{C}$ be an ∞ -category. A simplicial object $X_\bullet$ of $\mathcal{C}$ is 0-skeletal (in the sense of Definition 10.2.3.4) if and only if it is essentially constant (in the sense of Definition 10.2.3.1). See Proposition 10.2.3.2. 05G8

Example 10.2.3.6. Let $X_\bullet$ be a simplicial set and let n be an integer. Then $X_\bullet$ is *n-skeletal* (in the sense of Definition 10.2.3.4) if and only if it has dimension $\leq n$ (in the sense of Definition 1.1.3.1). This is a reformulation of Proposition 1.1.3.11 (see Remark 1.1.3.12). 05G9

Exercise 10.2.3.7. Let n be an integer. Show that a simplicial abelian group $A_\bullet$ is *n-skeletal* (when regarded as a simplicial object of the ∞ -category $N_\bullet(\text{Ab})$) if and only if the normalized Moore complex 05GA

$$\cdots \rightarrow N_2(A) \xrightarrow{\partial} N_1(A) \xrightarrow{\partial} N_0(A)$$

is concentrated in degrees $\leq n$: that is, the abelian group $N_k(A)$ vanishes for $k > n$. Beware that this condition does not guarantee that $A_\bullet$ is n -skeletal when regarded as a simplicial set.

05GB Remark 10.2.3.8 (Monotonicity). Let $X_\bullet$ be a simplicial object of an ∞ -category $\mathcal{C}$ and let $m \leq n$ be integers. If $X_\bullet$ is m -skeletal, then it is also n -skeletal. See Corollary 7.3.8.13.

05GC Remark 10.2.3.9. In the formulation of Definition 10.2.3.4, we allow n to be an arbitrary integer. However, for $n < 0$, the notion becomes degenerate: a simplicial object $X_\bullet$ is n -skeletal if and only if each X_m is an initial object of $\mathcal{C}$. In this case, $X_\bullet$ is an initial object in the ∞ -category of simplicial objects $\text{Fun}(N_\bullet(\Delta)^{\text{op}}, \mathcal{C})$.

To make Definition 10.2.3.4 more explicit, it will be convenient to introduce an auxiliary construction.

05GD Construction 10.2.3.10 (Degeneracy Cubes). Fix an integer $k \geq 0$, set $K = \{1, 2, \dots, k\}$, and let $\square^k = \square^K$ denote the simplicial cube of dimension k (Notation 2.4.5.2). Recall that $\square^k$ can be identified with the nerve of the set $P(K)$ of subsets of K , partially ordered with respect to inclusion.

For every subset $J \subseteq K$ having cardinality j , let $\alpha_J : [k] \rightarrow [j]$ denote the nondecreasing function which carries an element $k' \in [k]$ to the cardinality of the intersection $J \cap \{1, 2, \dots, k'\}$. The construction $J \mapsto \alpha_J$ then determines a functor from $P(K)^{\text{op}}$ to the coslice category $\Delta_{[k]/}$.

If $\mathcal{C}$ is an ∞ -category and $X_\bullet$ is a simplicial object of $\mathcal{C}$, we let $\sigma_k : \square^k \rightarrow \mathcal{C}$ denote the map given by the composition

$$\square^k \simeq N_\bullet(P(K)) \xrightarrow{J \mapsto \alpha_J} N_\bullet(\Delta_{[k]/})^{\text{op}} \rightarrow N_\bullet(\Delta)^{\text{op}} \xrightarrow{X_\bullet} \mathcal{C}.$$

We will refer to σ_k as the k th *degeneracy cube* of the simplicial object $X_\bullet$.

05GE Example 10.2.3.11. Let $X_\bullet$ be a simplicial object of an ∞ -category $\mathcal{C}$. For small values of k , the degeneracy cube $\sigma_k : \square^k \rightarrow \mathcal{C}$ of Construction 10.2.3.10 can be described more concretely:

- The degeneracy cube σ_0 can be identified with the object X_0 of $\mathcal{C}$.
- The degeneracy cube σ_1 can be identified with the degeneracy operator $s_0^0 : X_0 \rightarrow X_1$ of Notation 10.2.0.4.

- The degeneracy cube σ_2 is a square diagram

$$\begin{array}{ccc} X_0 & \xrightarrow{s_0^0} & X_1 \\ \downarrow s_0^0 & & \downarrow s_0^1 \\ X_1 & \xrightarrow{s_1^1} & X_2 \end{array}$$

which witnesses the identity $[s_0^1] \circ [s_0^0] = [s_1^1] \circ [s_0^0]$ in the homotopy category $\mathbf{hC}$.

Notation 10.2.3.12. Let k be a nonnegative integer. For every integer n , we let $\Delta_{[k]/}^{\leq n}$ 05GF denote the full subcategory of the coslice category $\Delta_{[k]/}$ spanned by objects which correspond to nondecreasing functions $[k] \rightarrow [m]$, where $m \leq n$.

Lemma 10.2.3.13. Let $k \geq 0$ and n be integers, let $K = \{1, \dots, k\}$, and let $P^{\leq n}(K)$ 05GG denote the partially ordered collection of all subsets $J \subseteq K$ which have cardinality $\leq n$. Then the assignment $J \mapsto \alpha_J$ of Construction 10.2.3.10 determines a right cofinal functor of ∞ -categories

$$\alpha : \mathbf{N}_\bullet(P^{\leq n}(K)) \rightarrow \mathbf{N}_\bullet(\Delta_{[k]/}^{\leq n})^{\text{op}}.$$

Proof. This is a special case of Corollary 7.2.3.7, since the functor α has a left adjoint (which carries a morphism $f : [k] \rightarrow [m]$ to the subset $J = \{j \in K : f(j-1) < f(j)\} \in P_{\leq n}(K)$). $\square$

Proposition 10.2.3.14. Let $\mathcal{C}$ be an ∞ -category, let $X_\bullet$ be a simplicial object of $\mathcal{C}$, and let 05GH n be an integer. The following conditions are equivalent:

- (1) The simplicial object $X_\bullet$ is n -skeletal, in the sense of Definition 10.2.3.4.
- (2) Let $k \geq 0$ be a nonnegative integer and set $K = \{1, 2, \dots, k\}$. Then the k th degeneracy cube

$$\sigma_k : \square^k = \mathbf{N}_\bullet(P(K)) \rightarrow \mathcal{C}$$

exhibits X_k as a colimit of the diagram $\sigma_k|_{\mathbf{N}_\bullet(P^{\leq n}(K))}$.

- (3) For every nonnegative integer $k > n$, the k -degeneracy cube σ_k is a colimit diagram in $\mathcal{C}$.

Proof. The equivalence (1) $\Leftrightarrow$ (2) follows immediately from Lemma 10.2.3.13 (together with Corollary 7.2.2.3). For each integer $k \geq 0$, set $K = \{1, 2, \dots, k\}$ and consider the following conditions:

- (2_k) The degeneracy cube $\sigma_k : \mathbf{N}_\bullet(P(K)) \rightarrow \mathcal{C}$ exhibits X_k as a colimit of the diagram $\sigma_k|_{\mathbf{N}_\bullet(P^{\leq n}(K))}$.
- (3_k) The degeneracy cube σ_k is a colimit diagram in $\mathcal{C}$.

Note that condition (2_k) is automatic for $k \leq n$. We will complete the proof by showing that if $k > n$ and condition (2_ℓ) is satisfied for every integer $0 \leq \ell < k$, then conditions (2_k) and (3_k) are equivalent. Our hypothesis that condition (2_ℓ) is satisfied for $\ell < k$ guarantees that the functor $\sigma_k|_{N_\bullet(P^{\leq k-1}(K))}$ is left Kan extended from the full subcategory $N_\bullet(P^{\leq n}(K)) \subseteq N_\bullet(P^{\leq k-1}(K))$. The equivalence of (2_k) and (3_k) is therefore a special case of Corollary 7.3.8.3. $\square$

05GJ Remark 10.2.3.15. Let $\mathcal{C}$ be an ∞ -category and let n be an integer. Using Proposition 10.2.3.14, we see that the condition that a simplicial object $X_\bullet$ of $\mathcal{C}$ is n -skeletal depends only on the restriction of $X_\bullet$ to the (non-full) subcategory $N_\bullet(\Delta_{\text{surj}})^{\text{op}} \subset N_\bullet(\Delta)^{\text{op}}$ (see Notation 1.1.2.12). Stated more informally (and slightly incorrectly), the condition of n -skeletality depends only on the degeneracy operators of $X_\bullet$, and not on its face operators.

05GK Corollary 10.2.3.16. *Let $\mathcal{C}$ be an ∞ -category and let $n \geq 0$ be an integer. Then a simplicial object $X_\bullet$ of $\mathcal{C}$ is $(n-1)$ -skeletal if and only if it is n -skeletal and the degeneracy cube $\sigma_n : \square^n \rightarrow \mathcal{C}$ is a colimit diagram in $\mathcal{C}$.*

05GL Corollary 10.2.3.17. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories and let $n \geq 0$ be an integer. Assume that $\mathcal{C}$ admits pushouts and that F preserves pushouts. If $X_\bullet$ is an n -skeletal simplicial object of $\mathcal{C}$, then $F(X_\bullet)$ is an n -skeletal simplicial object of $\mathcal{D}$.*

Proof. Fix an integer $k > n$, and let $\sigma_k : \square^k \rightarrow \mathcal{C}$ be the k th degeneracy cube of the simplicial object $X_\bullet$. Set $K = \{1, 2, \dots, k\}$, and let $P^{>0}(K)$ denote the collection of all nonempty subsets of K . Then σ_k can be identified with a functor σ_k° from $N_\bullet(P^{>0}(K))$ to the coslice ∞ -category $\mathcal{C}_{X_0/}$. Our assumption that $X_\bullet$ is n -skeletal guarantees that σ_k is a colimit diagram in $\mathcal{C}$ (Proposition 10.2.3.14), or equivalently that σ_k° is a colimit diagram in the ∞ -category $\mathcal{C}_{X_0/}$ (Remark 7.1.3.12). Since the functor F preserves pushouts, the induced functor of coslice ∞ -categories $F_{X_0/} : \mathcal{C}_{X_0/} \rightarrow \mathcal{D}_{F(X_0)/}$ preserves finite colimits (Example 7.6.2.31). In particular, $F_{X_0/} \circ \sigma_k^\circ$ is a colimit diagram in the ∞ -category $\mathcal{D}_{F(X_0)/}$, so that $F \circ \sigma_k$ is a colimit diagram in $\mathcal{D}$ (Remark 7.1.3.12). Allowing k to vary, we conclude that $F(X_\bullet)$ is an n -skeletal simplicial object of $\mathcal{D}$ (Proposition 10.2.3.14). $\square$

Let $X = X_\bullet$ be a simplicial set. Recall that the n -skeleton of X is the largest simplicial subset $\text{sk}_n(X) \subseteq X$ of dimension $\leq n$ (see Construction 1.1.4.1 and Corollary 1.1.4.7). This construction has a counterpart for more general simplicial objects.

05GM Definition 10.2.3.18. Let $\mathcal{C}$ be an ∞ -category, let $u : Y_\bullet \rightarrow X_\bullet$ be a morphism between simplicial objects of $\mathcal{C}$, and let n be an integer. We will say that u *exhibits $Y_\bullet$ as an n -skeleton of $X_\bullet$* if the following conditions are satisfied:

- The simplicial object $Y_\bullet$ is n -skeletal.

- For $0 \leq m \leq n$, the induced map $Y_m \rightarrow X_m$ is an isomorphism in the ∞ -category $\mathcal{C}$.

Example 10.2.3.19. Let $X = X_\bullet$ be a simplicial set. For every integer n , the inclusion of simplicial sets $\text{sk}_n(X) \hookrightarrow X$ exhibits $\text{sk}_n(X)$ as an n -skeleton of X , in the sense of Definition 10.2.3.18: see Proposition 1.1.4.6. 05GN

Remark 10.2.3.20 (Uniqueness). Let $\mathcal{C}$ be an ∞ -category, let $X_\bullet$ be a simplicial object of $\mathcal{C}$, and let n be an integer. If there exists a morphism of simplicial objects $u : Y_\bullet \rightarrow X_\bullet$ which exhibits $Y_\bullet$ as an n -skeleton of $X_\bullet$, then $Y_\bullet$ is uniquely determined up to isomorphism and depends functorially on $X_\bullet$. To emphasize this dependence, we will denote the object $Y_\bullet$ by $\text{sk}_n(X)$ and refer to it as the n -skeleton of $X_\bullet$. By virtue of Example 10.2.3.19, this reduces to the standard definition in the special case where $\mathcal{C}$ is (the nerve of) the category of sets. 05GP

Using Corollary 7.3.6.13, we see that the n -skeleton of a simplicial object $X_\bullet$ is characterized by the following universal mapping property:

- If $Z_\bullet$ is any n -skeletal simplicial object of $\mathcal{C}$, then composition with u induces a homotopy equivalence of mapping spaces

$$\text{Hom}_{\text{Fun}(N_\bullet(\Delta)^{\text{op}}, \mathcal{C})}(Z_\bullet, \text{sk}_n(X_\bullet)) \rightarrow \text{Hom}_{\text{Fun}(N_\bullet(\Delta)^{\text{op}}, \mathcal{C})}(Z_\bullet, X_\bullet).$$

Example 10.2.3.21. Let $A_\bullet$ be a simplicial abelian group and let $N_*(A)$ denote the normalized Moore complex of $A_\bullet$ (Construction 2.5.5.7). For every integer $n \geq 0$, let $N_{\leq n}(A)$ denote the subcomplex of $N_*(A)$ depicted in the diagram 05GQ

$$\cdots \rightarrow 0 \rightarrow N_n(A) \xrightarrow{\partial} N_{n-1}(A) \rightarrow \cdots \rightarrow N_1(A) \xrightarrow{\partial} N_0(A) \rightarrow 0 \rightarrow \cdots$$

Then the inclusion map

$$K(N_{\leq n}(A)) \hookrightarrow K(N_*(A)) \simeq A_\bullet$$

exhibits the Eilenberg-MacLane space $K(N_{\leq n}(A))$ as an n -skeleton of $A_\bullet$ in the category of simplicial abelian groups. Beware that the image of this inclusion is usually larger than the n -skeleton of $A_\bullet$ as a simplicial set (see Exercise 10.2.3.7).

Example 10.2.3.22 (0-Skeleta). Let $\mathcal{C}$ be an ∞ -category, let $X_\bullet$ be a simplicial object of $\mathcal{C}$, and set $C = X_0$. Then the constant simplicial object $\underline{C}$ is an n -skeleton of $X_\bullet$. More precisely, the identity morphism $\text{id} : C \xrightarrow{\sim} X_0$ admits an (essentially unique) extension to a morphism of simplicial objects $\underline{C} \rightarrow X_\bullet$ which exhibits $\underline{C}$ as a 0-skeleton of $X_\bullet$. 05GR

Proposition 10.2.3.23 (Existence of Skeleta). Let $\mathcal{C}$ be an ∞ -category and let $n \geq 0$ be an integer. If $\mathcal{C}$ admits pushouts, then every simplicial object $X_\bullet$ of $\mathcal{C}$ admits an n -skeleton. 05GS

Proof. We will show that the functor

$$N_{\bullet}(\Delta^{\leq n})^{\text{op}} \hookrightarrow N_{\bullet}(\Delta)^{\text{op}} \xrightarrow{X_{\bullet}} \mathcal{C}$$

admits a left Kan extension $Y_{\bullet} : N_{\bullet}(\Delta)^{\text{op}} \rightarrow \mathcal{C}$; Corollary 7.3.6.13 then guarantees that there is an (essentially unique) morphism of simplicial objects $u : Y_{\bullet} \rightarrow X_{\bullet}$ which is the identity when restricted to $N_{\bullet}(\Delta^{\leq n})^{\text{op}}$. By virtue of Corollary 7.3.5.8, it will suffice to show that for every integer $k > n$, the diagram

$$F : N_{\bullet}(\Delta_{[k]}^{\leq n})^{\text{op}} \rightarrow N_{\bullet}(\Delta^{\leq n})^{\text{op}} \xrightarrow{X_{\bullet}} \mathcal{C}$$

admits a colimit. Set $K = \{1, 2, \dots, k\}$, let $P^{\leq n}(K)$ denote the collection of all subsets of K having cardinality $\leq n$, and let F_0 denote the composition of F with the right cofinal functor

$$N_{\bullet}(P^{\leq n}(K)) \rightarrow N_{\bullet}(\Delta_{[k]}^{\leq n})^{\text{op}}$$

supplied by Lemma 10.2.3.13. Let $Q \subseteq P^{\leq n}(K)$ denote the collection of nonempty subsets of K of cardinality $\leq n$, so that F_0 can be identified with a functor $G : N_{\bullet}(Q) \rightarrow \mathcal{C}_{X_0/}$. Since $\mathcal{C}$ admits pushouts, the coslice ∞ -category $\mathcal{C}_{X_0/}$ admits finite limits (Example 7.6.2.31). In particular, the functor G admits a colimit in $\mathcal{C}_{X_0/}$, which we can identify with a colimit of F_0 in the ∞ -category $\mathcal{C}$ (Remark 7.1.3.12). $\square$

05GT Warning 10.2.3.24. If $X = X_{\bullet}$ is a simplicial set, then the comparison map $\text{sk}_n(X) \rightarrow X$ is a monomorphism of simplicial sets. Beware that the analogous statement is generally false for simplicial objects of more general ∞ -categories.

10.2.4 Coskeletal Simplicial Objects

05GU Let S be a set. For each $n \geq 0$, we let $\check{C}_n(S) = \text{Hom}([n], S)$ denote the collection of functions from the set $[n] = \{0 < 1 < \dots < n\}$ into S . The construction $[n] \mapsto \check{C}_n(S)$ determines a simplicial set $\check{C}_{\bullet}(S)$, which we will refer to as the *Čech nerve* of S . In this section, we study an ∞ -categorical counterpart of this construction.

04SW Definition 10.2.4.1. Let $\mathcal{C}$ be an ∞ -category and let $X_{\bullet}$ be a simplicial object of $\mathcal{C}$. We will say that $X_{\bullet}$ is a *Čech nerve* if, for every integer $n \geq 0$, the following condition is satisfied:

($*_n$) For $0 \leq i \leq n$, let $\nu_i : X_n \rightarrow X_0$ be the morphism of $\mathcal{C}$ induced by the inclusion $[0] \simeq \{i\} \subseteq [n]$. Then the morphisms $\{\nu_i\}_{0 \leq i \leq n}$ exhibit X_n as a product of $(n+1)$ -copies of X_0 .

04SX Remark 10.2.4.2. Let $\mathcal{C}$ be an ∞ -category and let $C_{\bullet} : N_{\bullet}(\Delta)^{\text{op}} \rightarrow \mathcal{C}$ be a simplicial object of $\mathcal{C}$. Then $X_{\bullet}$ is a Čech nerve if and only if it is right Kan extended from the full subcategory of $N_{\bullet}(\Delta)^{\text{op}}$ spanned by the object $[0]$.

Definition 10.2.4.3. Let $\mathcal{C}$ be an ∞ -category and let X be an object of $\mathcal{C}$. We will say 04SY that a simplicial object $X_\bullet$ of $\mathcal{C}$ is a *Čech nerve of X* if $X_\bullet$ is a Čech nerve (in the sense of Definition 10.2.4.1) and $X_0 = X$.

Notation 10.2.4.4. Let $\mathcal{C}$ be an ∞ -category and let X be an object of $\mathcal{C}$ which admits a 04SZ Čech nerve $X_\bullet$. It follows from Corollary 7.3.6.13 that, for every simplicial object $Y_\bullet$ of $\mathcal{C}$, the restriction map

$$\mathrm{Hom}_{\mathrm{Fun}(\Delta^{\mathrm{op}}, \mathcal{C})}(Y_\bullet, X_\bullet) \rightarrow \mathrm{Hom}_{\mathcal{C}}(Y_0, X_0) = \mathrm{Hom}_{\mathcal{C}}(Y_0, X)$$

is a homotopy equivalence. In particular, the simplicial object $X_\bullet$ is unique up to isomorphism and depends functorially on X . To emphasize this dependence, we will denote $X_\bullet$ by $\check{C}_\bullet(X)$ and refer to it as *the Čech nerve of the object X* .

Proposition 10.2.4.5 (Existence). *Let $\mathcal{C}$ be an ∞ -category and let X be an object of $\mathcal{C}$. 04T0 Then X admits a Čech nerve $\check{C}_\bullet(X)$ if and only if, for every nonempty finite set J , there exists a product of J copies of X in the ∞ -category $\mathcal{C}$.*

Proof. For every integer $n \geq 0$, the category $\{[0]\} \times_{\Delta} \Delta_{/[n]}$ is isomorphic to the finite set $\{0, 1, \dots, n\}$, regarded as a category having only identity morphisms. By virtue of Remark 10.2.4.2, the desired result is a special case of the existence criterion for Kan extensions (Corollary 7.3.5.8). $\square$

Corollary 10.2.4.6. *Let $\mathcal{C}$ be an ∞ -category which admits finite products. Then every 04T1 object $X \in \mathcal{C}$ admits a Čech nerve $\check{C}_\bullet(X)$.*

Remark 10.2.4.7. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories which preserves finite 04T2 products. Then the induced functor $\mathrm{Fun}(N_\bullet(\Delta)^{\mathrm{op}}, \mathcal{C}) \rightarrow \mathrm{Fun}(N_\bullet(\Delta)^{\mathrm{op}}, \mathcal{D})$ carries Čech nerves to Čech nerves. In particular, if X is an object of $\mathcal{C}$ which admits a Čech nerve $\check{C}_\bullet(X)$, then the image $Y = F(X)$ also admits a Čech nerve, given by $\check{C}_\bullet(Y) = F(\check{C}_\bullet(X))$.

Corollary 10.2.4.8. *Let $\mathcal{C}$ be an ∞ -category which admits finite products. Then the 04T3 evaluation functor*

$$\mathrm{Fun}(N_\bullet(\Delta)^{\mathrm{op}}, \mathcal{C}) \rightarrow \mathcal{C} \quad X_\bullet \mapsto X_0$$

admits a right adjoint, given on objects by the Čech nerve $X \mapsto \check{C}_\bullet(X)$.

Proof. Combine Corollaries 10.2.4.6 and 7.3.6.4. $\square$

We now introduce a generalization of Definition 10.2.4.1.

Definition 10.2.4.9. Let $\mathcal{C}$ be an ∞ -category and let n be an integer. We say that a 05GV simplicial object $X_\bullet$ of $\mathcal{C}$ is *n -coskeletal* if the functor

$$N_\bullet(\Delta)^{\mathrm{op}} \xrightarrow{X_\bullet} \mathcal{C}$$

is right Kan extended from the full subcategory $N_\bullet(\Delta^{\leq n})^{\mathrm{op}} \subseteq N_\bullet(\Delta)^{\mathrm{op}}$.

05GW **Example 10.2.4.10.** Let $\mathcal{C}$ be an ∞ -category. A simplicial object $X_\bullet$ of $\mathcal{C}$ is 0-coskeletal if and only if it is a Čech nerve (Remark 10.2.4.2).

05GX **Example 10.2.4.11.** Let $X_\bullet$ be a simplicial set and let n be an integer. The following conditions are equivalent:

- The simplicial set $X_\bullet$ is n -coskeletal in the sense of Definition 3.5.3.1: that is, the restriction map $\mathrm{Hom}_{\mathrm{Set}_\Delta}(\Delta^m, X) \rightarrow \mathrm{Hom}_{\mathrm{Set}_\Delta}(\partial\Delta^m, X)$ is bijective for $m > n$.
- The simplicial set $X_\bullet$ is n -coskeletal in the sense of Definition 10.2.4.9: that is, it is a right Kan extension of its restriction to (the opposite of) the subcategory $\Delta^{\leq n} \subset \Delta$.

This is a restatement of Corollary 3.5.3.13 (see Remark 3.5.3.14).

05GY **Remark 10.2.4.12** (Monotonicity). Let $X_\bullet$ be a simplicial object of an ∞ -category $\mathcal{C}$ and let $m \leq n$ be integers. If $X_\bullet$ is m -coskeletal, then it is also n -coskeletal. See Corollary 7.3.8.13.

05GZ **Remark 10.2.4.13.** In the formulation of Definition 10.2.4.9, we allow n to be an arbitrary integer. However, for $n < 0$, the notion becomes degenerate: a simplicial object $X_\bullet$ is n -coskeletal if and only if each X_m is a final object of $\mathcal{C}$. In this case, $X_\bullet$ is a final object of the ∞ -category of simplicial objects $\mathrm{Fun}(\mathbf{N}_\bullet(\Delta)^{\mathrm{op}}, \mathcal{C})$.

Definition 10.2.4.9 has a counterpart for semisimplicial objects.

05H0 **Variant 10.2.4.14.** For every integer n , we let $\Delta_{\mathrm{inj}}^{\leq n} = \Delta_{\mathrm{inj}} \cap \Delta^{\leq n}$ denote the category whose objects are linearly ordered sets $[m] = \{0 < 1 < \cdots < m\}$ for $0 \leq m \leq n$, and whose morphisms are strictly increasing functions. If $\mathcal{C}$ is an ∞ -category, we say that a semisimplicial object $X_\bullet : \mathbf{N}_\bullet(\Delta_{\mathrm{inj}})^{\mathrm{op}} \rightarrow \mathcal{C}$ is n -coskeletal if it is right Kan extended from the full subcategory $\mathbf{N}_\bullet(\Delta_{\mathrm{inj}}^{\leq n})^{\mathrm{op}}$.

05H1 **Proposition 10.2.4.15.** Let $\mathcal{C}$ be an ∞ -category, let n be an integer, and let $X_\bullet$ be a simplicial object of $\mathcal{C}$. Then $X_\bullet$ is n -coskeletal (in the sense of Definition 10.2.4.9) if and only if its underlying semisimplicial object is n -coskeletal (in the sense of Variant 10.2.4.14).

Proof. Fix an integer $k \geq 0$, $\Delta_{/[k]}^{\leq n}$ denote the full subcategory of $\Delta_{/[k]}$ spanned by those objects which correspond to nondecreasing functions $\alpha : [m] \rightarrow [k]$ where $m \leq n$, and let $\mathcal{J}$ be the full subcategory of $\Delta_{/[k]}^{\leq n}$ spanned by those objects where α is strictly increasing. Unwinding the definitions, we see that $X_\bullet$ is n -coskeletal if and only if, for every integer $k \geq 0$, the composite functor

$$F : \mathbf{N}_\bullet((\Delta_{/[k]}^{\leq n})^\triangleright) \hookrightarrow \mathbf{N}_\bullet(\Delta_{/[k]}^\triangleright) \rightarrow \mathbf{N}_\bullet(\Delta) \xrightarrow{X_\bullet} \mathcal{C}^{\mathrm{op}}$$

is a colimit diagram in the ∞ -category $\mathcal{C}^{\text{op}}$. Similarly, the underlying semisimplicial object of $X_\bullet$ is n -coskeletal if and only if, for every integer $k \geq 0$, the restriction $F|_{N_\bullet(\mathcal{J})^\triangleright}$ is a colimit diagram in $\mathcal{C}^{\text{op}}$. Consequently, to show that these conditions are equivalent, it will suffice to prove that the inclusion functor $N_\bullet(\mathcal{J}) \hookrightarrow N_\bullet(\Delta_{/[k]}^{\leq n})$ is right cofinal (Corollary 7.2.2.3). This is a special case of Corollary 7.2.3.7, since the inclusion functor $\mathcal{J} \hookrightarrow \Delta_{/[k]}^{\leq n}$ has a left adjoint (which carries a nondecreasing function $\alpha : [m] \rightarrow [k]$ to the inclusion map $\text{im}(\alpha) \hookrightarrow [k]$; here we abuse notation by identifying $\text{im}(\alpha)$ with the corresponding object of Δ). $\square$

Corollary 10.2.4.16. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories which preserves finite limits and let n be an integer. Then:* 05H2

- (1) *If $X_\bullet$ is an n -coskeletal simplicial object of $\mathcal{C}$, then $F(X_\bullet)$ is an n -coskeletal simplicial object of $\mathcal{D}$.*
- (2) *If $X_\bullet$ is an n -coskeletal semisimplicial object of $\mathcal{C}$, then $F(X_\bullet)$ is an n -coskeletal semisimplicial object of $\mathcal{D}$.*

Proof. Assertion (2) is immediate from the definitions (since the category $\mathcal{J}$ appearing in the proof of Proposition 10.2.4.15 is a finite partially ordered set). Assertion (1) follows by combining (2) with Proposition 10.2.4.15. $\square$

Recall that a morphism of simplicial sets $f : X_\bullet \rightarrow Y_\bullet$ exhibits $Y_\bullet$ as an n -coskeleton of $X_\bullet$ if $Y_\bullet$ is n -coskeletal and f is bijective on m -simplices for $m \leq n$. This notion has an obvious counterpart for simplicial objects in general:

Definition 10.2.4.17. Let $\mathcal{C}$ be an ∞ -category, let $u : X_\bullet \rightarrow Y_\bullet$ be a morphism between simplicial objects of $\mathcal{C}$, and let n be an integer. We will say that u exhibits $Y_\bullet$ as an n -coskeleton of $X_\bullet$ if the following conditions are satisfied: 05H3

- The simplicial object $Y_\bullet$ is n -coskeletal.
- For $0 \leq m \leq n$, the induced map $X_m \rightarrow Y_m$ is an isomorphism in the ∞ -category $\mathcal{C}$.

Remark 10.2.4.18. Definition 10.2.4.17 has an obvious counterpart for semisimplicial objects. If $u : X_\bullet \rightarrow Y_\bullet$ is a morphism between semisimplicial objects of an ∞ -category $\mathcal{C}$, we say that u exhibits $Y_\bullet$ as an n -coskeleton of $X_\bullet$ if $Y_\bullet$ is n -coskeletal and the morphism u induces an isomorphism $X_m \rightarrow Y_m$ for $0 \leq m \leq n$. By virtue of Proposition 10.2.4.15, this recovers Definition 10.2.4.17 in the case where u arises from a morphism between simplicial objects of $\mathcal{C}$. 05H4

05H5 **Remark 10.2.4.19** (Uniqueness). Let $\mathcal{C}$ be an ∞ -category, let $X_\bullet$ be a simplicial object of $\mathcal{C}$, and let n be an integer. If there exists a morphism of simplicial objects $u : X_\bullet \rightarrow Y_\bullet$ which exhibits $Y_\bullet$ as an n -coskeleton of $X_\bullet$, then $Y_\bullet$ is uniquely determined up to isomorphism and depends functorially on $X_\bullet$. To emphasize this dependence, we will denote the object $Y_\bullet$ by $\text{cosk}_n(X)_\bullet$ and refer to it as the n -coskeleton of $X_\bullet$. In the special case where $\mathcal{C}$ is (the nerve of) the category of sets, this recovers the convention of Notation 3.5.3.18.

Using Corollary 7.3.6.13, we see that the n -coskeleton of a simplicial object $X_\bullet$ is characterized by the following universal mapping property:

- If $Z_\bullet$ is any n -coskeletal simplicial object of $\mathcal{C}$, then composition with u induces a homotopy equivalence of mapping spaces

$$\text{Hom}_{\text{Fun}(\mathbf{N}_\bullet(\Delta)^{\text{op}}, \mathcal{C})}(\text{cosk}_n(X)_\bullet, Z_\bullet) \rightarrow \text{Hom}_{\text{Fun}(\mathbf{N}_\bullet(\Delta)^{\text{op}}, \mathcal{C})}(X_\bullet, Z_\bullet).$$

05H6 **Example 10.2.4.20.** Let $\mathcal{C}$ be an ∞ -category and let $C_\bullet$ be a simplicial object of $\mathcal{C}$. If the object $X = C_0$ admits a Čech nerve $\check{C}_\bullet(X)$ (Definition 10.2.4.3), then the identity map $C_0 \rightarrow X$ can be promoted to a morphism of simplicial objects $C_\bullet \rightarrow \check{C}_\bullet(X)$ (see Notation 10.2.4.4) which exhibits $\check{C}_\bullet(X)$ as a 0-coskeleton of $C_\bullet$.

05H7 **Proposition 10.2.4.21** (Existence of Coskeleta). *Let $\mathcal{C}$ be an ∞ -category which admits finite limits and let n be an integer. Then every (semi)simplicial object $X_\bullet$ of $\mathcal{C}$ admits an n -coskeleton $\text{cosk}_n(X)_\bullet$.*

Proof. We will prove the assertion for simplicial objects; the analogous statement for semisimplicial objects is similar (but easier). It will suffice to show that the functor

$$\mathbf{N}_\bullet(\Delta^{\leq n})^{\text{op}} \hookrightarrow \mathbf{N}_\bullet(\Delta)^{\text{op}} \xrightarrow{X_\bullet} \mathcal{C}$$

admits a right Kan extension $Y_\bullet : \mathbf{N}_\bullet(\Delta)^{\text{op}} \rightarrow \mathcal{C}$; Corollary 7.3.6.13 then guarantees that there is an (essentially unique) morphism of simplicial objects $u : X_\bullet \rightarrow Y_\bullet$ which is the identity when restricted to $\mathbf{N}_\bullet(\Delta^{\leq n})^{\text{op}}$. By virtue of Corollary 7.3.5.8, it will suffice to show that for every integer k , the diagram

$$G : \mathbf{N}_\bullet(\Delta^{\leq n}_{/[k]})^{\text{op}} \rightarrow \mathbf{N}_\bullet(\Delta)^{\text{op}} \xrightarrow{X_\bullet} \mathcal{C}$$

admits a limit. As in the proof of Proposition 10.2.4.15, we observe that the inclusion map $\mathbf{N}_\bullet(\mathcal{J}) \hookrightarrow \mathbf{N}_\bullet(\Delta^{\leq n}_{/[k]})$ is right cofinal, where $\mathcal{J} \subseteq \Delta^{\leq n}_{/[k]}$ is the full subcategory spanned by the injective maps $[m] \hookrightarrow [k]$. We are therefore reduced to showing that $G|_{\mathbf{N}_\bullet(\mathcal{J})^{\text{op}}}$ has a limit in $\mathcal{C}$ (Corollary 7.2.2.10), which follows from our assumption that $\mathcal{C}$ admits finite limits (since $\mathcal{J}$ is the category associated to a finite partially ordered set). $\square$

10.2.5 The Nerve of a Morphism

We now consider a relative version of Definition 10.2.4.1.

04SV

Definition 10.2.5.1. Let $\mathcal{C}$ be an ∞ -category and let $C_\bullet$ be an augmented simplicial object of $\mathcal{C}$, which we identify with a simplicial object $C'_\bullet$ of the ∞ -category $\mathcal{C}_{/C_{-1}}$ (see Remark 10.2.1.15). We will say that $C_\bullet$ is a *Čech nerve* if the simplicial object $C'_\bullet$ is a Čech nerve in the ∞ -category $\mathcal{C}_{/C_{-1}}$ (see Definition 10.2.4.1). 04T4

Remark 10.2.5.2. Let $\mathcal{C}$ be an ∞ -category. Stated more informally, an augmented simplicial object $C_\bullet$ of $\mathcal{C}$ is a Čech nerve if, for every integer $n \geq 0$, it exhibits C_n as an iterated fiber product 04T5

$$C_0 \times_{C_{-1}} C_0 \times_{C_{-1}} \cdots \times_{C_{-1}} C_0$$

(where the factor C_0 appears $n + 1$ times).

Remark 10.2.5.3. In the augmented simplex category Δ_+ , there is a unique morphism $\delta_0^0 : [-1] \rightarrow [0]$. This morphism determines a fully faithful functor $[1] \rightarrow \Delta_+$, whose image is the full subcategory $\Delta_+^{\leq 0} \subseteq \Delta_+$ spanned by the objects $[0]$ and $[-1]$. Combining Remarks 10.2.4.2 and 7.3.2.4, we see that an augmented simplicial object $X_\bullet$ of an ∞ -category $\mathcal{C}$ is a Čech nerve if and only if it is right Kan extended from the subcategory $N_\bullet(\Delta_+^{\leq 0})^{\text{op}} \subset N_\bullet(\Delta_+)^{\text{op}}$. 04T6

Definition 10.2.5.4. Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. We will say that an augmented simplicial object $C_\bullet$ of $\mathcal{C}$ is a *Čech nerve of f* if $C_\bullet$ is a Čech nerve (in the sense of Definition 10.2.5.1) and the face operator $d_0^0 : C_0 \rightarrow C_{-1}$ coincides with the morphism f (so that $C_0 = X$ and $C_{-1} = Y$). 04T7

Notation 10.2.5.5. Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. It follows from Remarks 10.2.5.3 and 7.3.6.6 that if f admits a Čech nerve $C_\bullet$, then the augmented simplicial object $C_\bullet$ is determined up to isomorphism and depends functorially on f . To emphasize this dependence, we will denote $C_\bullet$ by $\check{C}_\bullet(X/Y)$ and refer to it as *the Čech nerve of the morphism $f : X \rightarrow Y$* . Alternatively, we can identify $\check{C}_\bullet(X/Y)$ with the simplicial object of $\mathcal{C}_{/Y}$ given by the Čech nerve of f (in the sense of Notation 10.2.4.4). 04T8

Proposition 10.2.5.6. *Let $\mathcal{C}$ be an ∞ -category which admits pullbacks. Then every morphism $f : X \rightarrow Y$ in $\mathcal{C}$ admits a Čech nerve $\check{C}_\bullet(X/Y)$.* 04T9

Proof. Apply Corollary 10.2.4.6 to the ∞ -category $\mathcal{C}_{/Y}$, which admits finite products by virtue of our assumption that $\mathcal{C}$ admits pullbacks (Corollary 7.6.2.17). $\square$

Remark 10.2.5.7. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories which preserves fiber products. Then the induced functor of augmented simplicial objects 04TA

$$\text{Fun}(N_\bullet(\Delta_+^{\text{op}}), \mathcal{C}) \rightarrow \text{Fun}(N_\bullet(\Delta_+^{\text{op}}), \mathcal{D})$$

carries Čech nerves to Čech nerves (see Remark 10.2.4.7). In particular, if $u : X \rightarrow Y$ is a morphism of $\mathcal{C}$ which admits a Čech nerve $\check{C}_\bullet(X/Y)$, then the morphism $F(u) : F(X) \rightarrow F(Y)$ admits a Čech nerve in the ∞ -category $\mathcal{D}$, given by $F(\check{C}_\bullet(X/Y))$.

04TB **Corollary 10.2.5.8.** *Let $\mathcal{C}$ be an ∞ -category which admits pullbacks. Then the forgetful functor*

$$\mathrm{Fun}(\mathbf{N}_\bullet(\Delta_+^{\mathrm{op}}), \mathcal{C}) \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C}) \quad C_\bullet \mapsto (d_0^0 : C_0 \rightarrow C_{-1})$$

admits a right adjoint, given on objects by the construction $(f : X \rightarrow Y) \mapsto \check{C}_\bullet(X/Y)$.

Proof. Combine Proposition 10.2.5.6 with Corollary 7.3.6.4. $\square$

It will sometimes be useful to consider a generalization of Definition 10.2.5.1.

05H8 **Notation 10.2.5.9.** Let Δ_+ be the augmented simplex category (Definition 10.2.1.10). For every integer n , we let $\Delta_+^{\leq n}$ denote the full subcategory of Δ_+ spanned by the collection of objects $\{[m]\}_{-1 \leq m \leq n}$.

05H9 **Definition 10.2.5.10.** Let $\mathcal{C}$ be an ∞ -category and let n be an integer. We say that an augmented simplicial object $C_\bullet$ of $\mathcal{C}$ is *n -coskeletal* if the functor

$$C_\bullet : \mathbf{N}_\bullet(\Delta_+)^{\mathrm{op}} \rightarrow \mathcal{C}$$

is right Kan extended from the full subcategory $\mathbf{N}_\bullet(\Delta_+^{\leq n})^{\mathrm{op}}$.

05HA **Example 10.2.5.11.** Let $\mathcal{C}$ be an ∞ -category and let $C_\bullet$ be an augmented simplicial object of $\mathcal{C}$. Then $C_\bullet$ is 0-coskeletal (in the sense of Definition 10.2.5.10) if and only if it is a Čech nerve (in the sense of Definition 10.2.5.1). See Remark 10.2.5.3.

05HB **Example 10.2.5.12.** Let $\mathcal{C}$ be an ∞ -category. For $n \leq -2$, an augmented simplicial object $C_\bullet$ of $\mathcal{C}$ is *n -coskeletal* if and only if each C_m is a final object of $\mathcal{C}$.

05HC **Example 10.2.5.13.** Let $\mathcal{C}$ be an ∞ -category and let $C_\bullet$ be an augmented simplicial object of $\mathcal{C}$. The following conditions are equivalent:

- (1) The augmented simplicial object $C_\bullet$ is (-1) -coskeletal, in the sense of Definition 10.2.5.10.
- (2) The augmented simplicial object $C_\bullet$ is essentially constant: that is, it is isomorphic to a constant functor from $\mathbf{N}_\bullet(\Delta_+^{\mathrm{op}})$ to $\mathcal{C}$.
- (3) The functor $C_\bullet : \mathbf{N}_\bullet(\Delta_+^{\mathrm{op}}) \rightarrow \mathcal{C}$ carries each morphism in the category Δ_+^{op} to an isomorphism in the ∞ -category $\mathcal{C}$.
- (4) For every augmented simplicial object $X_\bullet$ of $\mathcal{C}$, the restriction map

$$\mathrm{Hom}_{\mathrm{Fun}(\mathbf{N}_\bullet(\Delta_+^{\mathrm{op}}), \mathcal{C})}(X_\bullet, C_\bullet) \rightarrow \mathrm{Hom}_{\mathcal{C}}(X_{-1}, C_{-1})$$

is a homotopy equivalence.

The equivalences $(1) \Leftrightarrow (2) \Leftrightarrow (3)$ are special cases of Corollary 7.3.3.14, since $[-1]$ is an initial object of the category Δ_+ . The equivalence $(1) \Leftrightarrow (4)$ follows from Corollary 7.3.6.13.

Variant 10.2.5.14. For every integer n , we let $\Delta_{+, \text{inj}}^{\leq n}$ denote the category whose objects are linearly ordered sets $[m] = \{0 < 1 < \cdots < n\}$ for $-1 \leq m \leq n$, and whose morphisms are strictly increasing functions. We say that an augmented semisimplicial object $C_\bullet$ of an ∞ -category $\mathcal{C}$ is *n-coskeletal* if the functor

$$C_\bullet : N_\bullet(\Delta_{+, \text{inj}})^{\text{op}} \rightarrow \mathcal{C}$$

is a right Kan extension of its restriction to $N_\bullet(\Delta_{+, \text{inj}}^{\leq n})^{\text{op}}$.

Remark 10.2.5.15. Let $\mathcal{C}$ be an ∞ -category and let $C_\bullet$ be an augmented simplicial object of $\mathcal{C}$, which we identify with a (semi)simplicial object $C'_\bullet$ of the slice ∞ -category $\mathcal{C}_{/C_{-1}}$ (see Remark 10.2.1.15). Then, for $n \geq -1$, the augmented simplicial object $C_\bullet$ is *n-coskeletal* (in the sense of Definition 10.2.5.10) if and only if the simplicial object $C'_\bullet$ is *n-coskeletal* (in the sense of Definition 10.2.4.9). Moreover, the analogous statement holds for semisimplicial objects. See Remark 7.3.2.4. 05HE

Warning 10.2.5.16. Let $\mathcal{C}$ be an ∞ -category and let $C_\bullet$ be an augmented simplicial object of $\mathcal{C}$. It follows from Remark 10.2.5.15 that if C_{-1} is a final object of $\mathcal{C}$, then $C_\bullet$ is *n-coskeletal* if and only if its underlying simplicial object is *n-coskeletal*. Beware that neither implication holds in general if we do not assume that C_{-1} is final. 05HF

Remark 10.2.5.17. Let $\mathcal{C}$ be an ∞ -category and let $C_\bullet$ be an augmented simplicial object of $\mathcal{C}$. For every integer n , the augmented simplicial object $C_\bullet$ is *n-coskeletal* (in the sense of Definition 10.2.5.10) if and only if its underlying augmented semisimplicial object is *n-coskeletal* (in the sense of Variant 10.2.5.14). For $n \leq -2$, this is trivial (see Example 10.2.5.12). For $n \geq -1$, it follows by combining Remark 10.2.5.15 with Proposition 10.2.4.15 (applied to the slice ∞ -category $\mathcal{C}_{/C_{-1}}$). 05HG

To make Definition 10.2.5.10 more concrete, it will be convenient to introduce a dual version of Construction 10.2.3.10.

Construction 10.2.5.18 (Face Cubes). Fix an integer $k \geq -1$, and let $\square^{k+1}$ be the simplicial cube of dimension $k+1$ (Notation 2.4.5.2). In what follows, we will identify $\square^{k+1}$ with the opposite of the nerve of the partially ordered set $P([k])$ of all subsets of $[k] = \{0 < 1 < \cdots < k\}$. Note that there is an isomorphism of categories $P([k]) \rightarrow (\Delta_{+, \text{inj}})_{/[k]}$, which carries each subset $J \subseteq [k]$ of cardinality $j+1$ to the unique strictly increasing function $[j] \hookrightarrow [k]$ having image J . If $C_\bullet$ is an augmented semisimplicial object of an ∞ -category $\mathcal{C}$, we let $\tau_k : \square^{k+1} \rightarrow \mathcal{C}$ denote the composite functor 05HH

$$\square^{k+1} \simeq N_\bullet((\Delta_{+, \text{inj}})_{/[k]})^{\text{op}} \rightarrow N_\bullet(\Delta_{+, \text{inj}}^{\text{op}}) \xrightarrow{C_\bullet} \mathcal{C}.$$

We will refer to τ_k as the *kth face cube* of the augmented semisimplicial object $C_\bullet$.

05HJ **Example 10.2.5.19.** Let $C_\bullet$ be an augmented semisimplicial object of an ∞ -category $\mathcal{C}$. For small values of k , the face cube $\tau_k : \square^{k+1} \rightarrow \mathcal{C}$ of Construction 10.2.5.18 can be described more explicitly:

- The face cube τ_{-1} can be identified with the object C_{-1} of $\mathcal{C}$.
- The face cube τ_0 can be identified with the face operator $d_0^0 : C_0 \rightarrow C_{-1}$.
- The face cube τ_1 is a square diagram

$$\begin{array}{ccc} C_1 & \xrightarrow{d_0^1} & C_0 \\ \downarrow d_1^1 & & \downarrow d_0^0 \\ C_0 & \xrightarrow{d_0^0} & C_{-1} \end{array}$$

which witnesses the identity $[d_0^0] \circ [d_1^1] = [d_0^0] \circ [d_1^1]$ in the homotopy category $\mathrm{h}\mathcal{C}$.

05HK **Proposition 10.2.5.20.** Let $\mathcal{C}$ be an ∞ -category, let $C_\bullet$ be an augmented semisimplicial object of $\mathcal{C}$, and let n be an integer. The following conditions are equivalent:

- (1) The augmented semisimplicial object $C_\bullet$ is $(n-1)$ -coskeletal, in the sense of Variant 10.2.5.14.
- (2) For each $k \geq n$, the face cube $\tau_k : \square^{k+1} \rightarrow \mathcal{C}$ of Construction 10.2.5.18 is a limit diagram in $\mathcal{C}$.

Proof. We proceed as in the proof of Proposition 10.2.3.14. Let us identify each τ_k with a functor $N_\bullet(P([k]))^{\mathrm{op}} \rightarrow \mathcal{C}$, where $P([k])$ denotes the collection of all subsets of $\{0 < 1 < \cdots < k\}$. Let $P^{\leq n}([k])$ denote the subset of $P([k])$ consisting of subsets of cardinality $\leq n$. Unwinding the definitions, we see that $C_\bullet$ is $(n-1)$ -coskeletal if and only if the following condition is satisfied for each $k \geq n$:

- (1_k) The functor τ_k exhibits C_k as a limit of its restriction to $N_\bullet(P^{\leq n}([k]))^{\mathrm{op}}$.

Similarly, (2) asserts that the following condition is satisfied for each $k \geq n$:

- (2_k) The face cube $\tau_k : \square^{k+1} \rightarrow \mathcal{C}$ of Construction 10.2.5.18 is a limit diagram in $\mathcal{C}$.

To complete the proof, it will suffice to show that if condition (1_ℓ) is satisfied for $n \leq \ell < k$, then conditions (1_k) and (2_k) are equivalent. Our hypothesis that condition (2_ℓ) is satisfied for $\ell < k$ guarantees that the functor $\tau_k|_{N_\bullet(P^{\leq k}([k]))^{\mathrm{op}}}$ is right Kan extended from the full subcategory $N_\bullet(P^{\leq n}([k]))^{\mathrm{op}} \subseteq N_\bullet(P^{\leq k}([k]))^{\mathrm{op}}$. The equivalence of (1_k) and (2_k) is therefore a special case of Corollary 7.3.8.3. $\square$

Corollary 10.2.5.21. *Let $\mathcal{C}$ be an ∞ -category and let $n \geq -1$ be an integer. Then an augmented (semi)simplicial object $C_\bullet$ of $\mathcal{C}$ is $(n-1)$ -coskeletal if and only if it is n -coskeletal and the face cube $\tau_n : \square^{n+1} \rightarrow \mathcal{C}$ is a limit diagram in $\mathcal{C}$.* 05HL

Corollary 10.2.5.22. *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories, let $C_\bullet$ be an augmented (semi)simplicial object of $\mathcal{C}$, and let $n \geq -1$ be an integer. Assume that $\mathcal{C}$ admits pullbacks and that F preserves pullbacks. If $C_\bullet$ is n -coskeletal, then the image $F(C_\bullet)$ is n -coskeletal.* 05HM

10.2.6 Split Simplicial Objects

We now introduce a tool which is often useful for computing geometric realizations of simplicial objects. 04S6

Notation 10.2.6.1. We define a category $\Delta_{\min}$ as follows: 04S7

- The objects of $\Delta_{\min}$ are linearly ordered sets $[n] = \{0 < 1 < \cdots < n\}$, where n is a nonnegative integer.
- A morphism from $[m]$ to $[n]$ in the category $\Delta_{\min}$ is a nondecreasing function $\alpha : [m] \rightarrow [n]$ satisfying $\alpha(0) = 0$.

Remark 10.2.6.2. By construction, the category $\Delta_{\min}$ is a (non-full) subcategory of the simplex category Δ of Definition 1.1.0.2. It can therefore also be regarded as a subcategory of the augmented simplex category Δ_+ of Definition 10.2.1.10. The inclusion functor $\Delta_{\min} \hookrightarrow \Delta_+$ admits a left adjoint $C_+ : \Delta_+ \rightarrow \Delta_{\min}$, given concretely by the construction $C_+([n]) = [0] \star [n] \simeq [n+1]$. We will refer to C_+ as the *concatenation functor*. We let $C : \Delta \rightarrow \Delta_{\min}$ denote the restriction of C_+ to the simplex category Δ , which we will also refer to as the *concatenation functor*. 04S8

Definition 10.2.6.3. Let $\mathcal{C}$ be an ∞ -category and let $X_\bullet$ be an augmented simplicial object of $\mathcal{C}$ (Definition 10.2.1.12). A *splitting* of $X_\bullet$ is a functor $\bar{X} : N_\bullet(\Delta_{\min}^{\text{op}}) \rightarrow \mathcal{C}$ for which the composition 04S9

$$N_\bullet(\Delta_+^{\text{op}}) \xrightarrow{C_+^{\text{op}}} N_\bullet(\Delta_{\min}^{\text{op}}) \xrightarrow{\bar{X}} \mathcal{C}$$

is equal to $X_\bullet$; here C_+ denotes the concatenation functor $[n] \mapsto [n] \star [0]$ of Remark 10.2.6.2. We will say that the augmented simplicial object $X_\bullet$ is *split* if there exists a splitting of $X_\bullet$.

Remark 10.2.6.4 (Extra Degeneracies). Let $\mathcal{C}$ be an ∞ -category and let $X_\bullet$ be an augmented simplicial object of $\mathcal{C}$. For every integer $n \geq -1$, the function 04SA

$$\sigma_{n+1}^0 : [n+2] \rightarrow [n+1] \quad i \mapsto \begin{cases} 0 & \text{if } i = 0 \\ i-1 & \text{if } i > 0 \end{cases}$$

belongs to the subcategory $\Delta_{\min} \subseteq \Delta$. If $\overline{X}$ is a splitting of $X_\bullet$, then evaluation on σ_{n+1}^0 determines a morphism

$$h_n : X_n = \overline{X}([n+1]) \rightarrow \overline{X}([n+2]) = X_{n+1}.$$

Heuristically, one can think of the morphisms $\{h_n\}_{n \geq -1}$ as “extra” degeneracy operators on the augmented simplicial object $X_\bullet$. In the homotopy category $\mathrm{h}\mathcal{C}$, these operators satisfy the identities

$$04\mathrm{SB} \quad d_i^{n+1} \circ h_n \sim \begin{cases} \mathrm{id}_{X_n} & \text{if } i = 0 \\ h_{n-1} \circ d_{i-1}^n & \text{otherwise} \end{cases} \quad (10.2)$$

$$04\mathrm{SC} \quad s_i^{n+1} \circ h_n \sim \begin{cases} h_{n+1} \circ h_n & \text{if } i = 0 \\ h_{n+1} \circ s_{i-1}^n & \text{otherwise.} \end{cases} \quad (10.3)$$

04SD **Exercise 10.2.6.5.** Let $\mathcal{C}$ be an ordinary category and let $X_\bullet$ be an augmented simplicial object of $\mathcal{C}$. Show that the construction of Remark 10.2.6.4 determines a bijection from the set of splittings of $X_\bullet$ (in the sense of Definition 10.2.6.3) to the collection of systems $\{h_n : X_n \rightarrow X_{n+1}\}_{n \geq -1}$ satisfying the identities (10.2) and (10.3).

04SE **Example 10.2.6.6.** Let $A_\bullet$ be an augmented simplicial abelian group, and let

$$C_*^{\mathrm{aug}}(A) = (\cdots \rightarrow A_2 \xrightarrow{\partial} A_1 \xrightarrow{\partial} A_0 \xrightarrow{\partial} A_{-1})$$

denote its augmented Moore complex (Remark 10.2.2.21). Suppose we are given a splitting of $A_\bullet$, and let $\{h_n : A_n \rightarrow A_{n+1}\}_{n \geq -1}$ be the extra degeneracy operators described in Remark 10.2.6.4. Then the collection $\{h_n\}$ is a contracting homotopy for $C_*^{\mathrm{aug}}(A)$, in the sense of Definition 2.5.0.5: that is, the homomorphism

$$(h_{n-1} \circ \partial + \partial \circ h_n) : A_n \rightarrow A_n$$

is equal to the identity for each $n \geq -1$ (where we adopt the convention that $h_n \circ \partial = 0$ for $n = -1$). This follows from the calculation

$$\begin{aligned} h_{n-1} \circ \partial + \partial \circ h_n &= \left(\sum_{i=0}^n (-1)^i h_{n-1} \circ d_i^n \right) + \left(\sum_{j=0}^{n+1} (-1)^j d_j^{n+1} \circ h_n \right) \\ &= \left(\sum_{i=0}^n (-1)^i (h_{n-1} \circ d_i^n - d_{i+1}^{n+1} \circ h_n) \right) + d_0^{n+1} \circ h_n \\ &= \mathrm{id}_{A_n}. \end{aligned}$$

where the final equality follows from the identities (10.2).

Variant 10.2.6.7. In the situation of Example 10.2.6.6, let $N_*^{\text{aug}}(A)$ denote the augmented 04SF normalized Moore complex of $A_\bullet$ (Variant 10.2.2.22). It follows from (10.3) that, for every integer $n \geq 0$, the operator

$$C_n^{\text{aug}}(A) = A_n \xrightarrow{h_n} A_{n+1} = C_{n+1}^{\text{aug}}(A)$$

carries degenerate n -simplices of $A_\bullet$ to degenerate $(n+1)$ -simplices of $A_\bullet$, and therefore descends to an operator $\bar{h}_n : N_n^{\text{aug}}(A) \rightarrow N_{n+1}^{\text{aug}}(A)$. The collection of homomorphisms $\{\bar{h}_n\}$ then determine a contracting homotopy for the chain complex $N_*^{\text{aug}}(A)$.

Warning 10.2.6.8. Let $A_\bullet$ be an augmented simplicial abelian group. In general, not 04SG every contracting homotopy for the chain complex $N_*^{\text{aug}}(A)$ can be obtained from the construction of Variant 10.2.6.7. A splitting of $A_\bullet$ determines a system of homomorphisms $\{h_n : A_n \rightarrow A_{n+1}\}_{n \geq 0}$ which satisfy the identity $h_{n+1} \circ h_n = s_0^{n+1} \circ h_n$ (Remark 10.2.6.4). In particular, the composition $h_{n+1} \circ h_n$ carries every n -simplex of $A_\bullet$ to a degenerate $(n+2)$ -simplex of $A_\bullet$. It follows that the composite map

$$N_n^{\text{aug}}(A) \xrightarrow{\bar{h}_n} N_{n+1}^{\text{aug}}(A) \xrightarrow{\bar{h}_{n+1}} N_{n+2}^{\text{aug}}(A)$$

vanishes; for a general contracting homotopy, the analogous statement need not be true.

The utility of Definition 10.2.6.3 stems from the following:

Proposition 10.2.6.9. Let $\mathcal{C}$ be an ∞ -category and let $X_\bullet$ be an augmented simplicial 04SH object of $\mathcal{C}$. If $X_\bullet$ is split, then it is a colimit diagram in $\mathcal{C}$.

Proof. Let $\bar{X} : N_\bullet(\Delta_{\min}^{\text{op}}) \rightarrow \mathcal{C}$ be a splitting of $X_\bullet$, and let $C_+ : \Delta_+ \rightarrow \Delta_{\min}$ denote the concatenation functor of Remark 10.2.6.2. Let us abuse notation by identifying $N_\bullet(\Delta_+^{\text{op}})$ with the cone $N_\bullet(\Delta^{\text{op}})^\triangleright$. We wish to show that the augmented simplicial object

$$(X_\bullet = \bar{X} \circ N_\bullet(C_+^{\text{op}})) : N_\bullet(\Delta^{\text{op}})^\triangleright \rightarrow \mathcal{C}$$

is a colimit diagram in $\mathcal{C}$.

Note that $[0]$ is initial when viewed as an object of the category $\Delta_{\min}$, and therefore final when viewed as an object of the ∞ -category $N_\bullet(\Delta_{\min}^{\text{op}})$. Unwinding the definitions, we see that the functor $N_\bullet(C_+^{\text{op}})$ factors as a composition

$$N_\bullet(\Delta^{\text{op}})^\triangleright \xrightarrow{N_\bullet(C)^\triangleright} N_\bullet(\Delta_{\min}^{\text{op}})^\triangleright \xrightarrow{R} N_\bullet(\Delta_{\min}^{\text{op}}),$$

where R is the identity when restricted to $N_\bullet(\Delta_{\min}^{\text{op}})$ and carries the cone point of $N_\bullet(\Delta_{\min}^{\text{op}})^\triangleright$ to $[0]$. Applying Corollary 7.2.2.6, we deduce that $(\bar{X} \circ R) : N_\bullet(\Delta_{\min}^{\text{op}})^\triangleright \rightarrow \mathcal{C}$ is a colimit diagram. Consequently, to show that $X_\bullet$ is a colimit diagram, it will suffice to show that the functor $N_\bullet(C^{\text{op}}) : N_\bullet(\Delta^{\text{op}}) \rightarrow N_\bullet(\Delta_{\min}^{\text{op}})$ is right cofinal (Corollary 7.2.2.3). This is a special case of Corollary 7.2.3.7, since the concatenation functor C is left adjoint to the inclusion $\Delta_{\min} \hookrightarrow \Delta$ (Remark 10.2.6.2). $\square$

04SJ **Remark 10.2.6.10.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories and let $X_\bullet$ be an augmented simplicial object of $\mathcal{C}$, so that $F(X_\bullet)$ is an augmented cosimplicial object of $\mathcal{D}$. Composition with the functor F carries splittings of $X_\bullet$ to splittings of $F(X_\bullet)$. Consequently, if $X_\bullet$ is split, then $F(X_\bullet)$ is also split. In particular, if $X_\bullet$ is split, then $F(X_\bullet)$ is a colimit diagram in $\mathcal{D}$ (Proposition 10.2.6.9).

04SK **Variant 10.2.6.11.** Let $\mathcal{C}$ be an ∞ -category and let $X_\bullet$ be a simplicial object of $\mathcal{C}$. A *splitting* of $X_\bullet$ is a functor $\overline{X} : N_\bullet(\Delta_{\min}^{\text{op}}) \rightarrow \mathcal{C}$ for which the composition

$$N_\bullet(\Delta^{\text{op}}) \xrightarrow{C^{\text{op}}} N_\bullet(\Delta_{\min}^{\text{op}}) \xrightarrow{\overline{X}} \mathcal{C}$$

is equal to $X_\bullet$; here C denotes the concatenation functor $[n] \mapsto [n] \star [0]$ of Remark 10.2.6.2. We will say that the simplicial object $X_\bullet$ is *split* if there exists a splitting of $X_\bullet$.

04SL **Warning 10.2.6.12.** The terminology of Variant 10.2.6.11 (and Definition 10.2.6.3) is potentially confusing. We will use the term *split simplicial object* to refer to a simplicial object $X_\bullet$ of an ∞ -category $\mathcal{C}$ for which there *exists* a splitting $\overline{X} : N_\bullet(\Delta_{\min}^{\text{op}}) \rightarrow \mathcal{C}$. Unless otherwise specified, we do not assume that a particular splitting has been chosen. Beware that $\overline{X}$ is not uniquely determined by $X_\bullet$. However, the underlying augmented simplicial object

$$N_\bullet(\Delta_+^{\text{op}}) \xrightarrow{N_\bullet(C_+^{\text{op}})} N_\bullet(\Delta_{\min}) \xrightarrow{\overline{X}} \mathcal{C}$$

is determined up to isomorphism by $X_\bullet$: by virtue of Proposition 10.2.6.9, it is an extension of $X_\bullet$ to a colimit diagram in $\mathcal{C}$.

04SM **Corollary 10.2.6.13.** *Let $X_\bullet$ be a split simplicial object of an ∞ -category $\mathcal{C}$. Then $X_\bullet$ admits a geometric realization $|X_\bullet|$. Moreover, the geometric realization of $X_\bullet$ is preserved by any functor of ∞ -categories $F : \mathcal{C} \rightarrow \mathcal{D}$.*

Proof. The first assertion follows from Proposition 10.2.6.9, and the second from Remark 10.2.6.10. $\square$

The Čech nerve construction of §10.2.5 provides an abundant supply of split simplicial objects.

05HN **Proposition 10.2.6.14.** *Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$ which admits a Čech nerve $\check{C}_\bullet(X/Y)$. Then the augmented simplicial object $\check{C}_\bullet(X/Y)$ splits if and only if f admits a right homotopy inverse.*

04TL **Corollary 10.2.6.15.** *Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$ which admits a Čech nerve $\check{C}_\bullet(X/Y)$. If f admits a right homotopy inverse, then $\check{C}_\bullet(X/Y)$ is a colimit diagram: that is, it exhibits Y as a geometric realization of its underlying simplicial object.*

Proof. Combine Propositions 10.2.6.14 and 10.2.6.9. $\square$

Our proof of Proposition 10.2.6.14 will require some preliminaries.

Notation 10.2.6.16. Let $\Delta_{\min}$ be the category introduced in Notation 10.2.6.1. For every integer n , we let $\Delta_{\min}^{\leq n}$ denote the full subcategory of $\Delta_{\min}$ spanned by the collection of objects $\{[m]\}_{0 \leq m \leq n}$. 05HP

Example 10.2.6.17. For $n < 0$, the category $\Delta_{\min}^{\leq n}$ is empty. For $n = 0$, it contains a single object $[0]$, and no morphisms other than the identity morphism. 05HQ

Example 10.2.6.18. Let Ret be the category introduced in Construction 8.5.0.2: that is, the category which is freely generated by a pair of morphisms $i : Y \rightarrow X$ and $r : X \rightarrow Y$ satisfying the identity $r \circ i = \text{id}_Y$. By virtue of Exercise 8.5.0.3, there is a unique functor $\text{Ret} \rightarrow \Delta$ which carries i to the inclusion map $[0] \hookrightarrow [1]$ and r to the constant function $[1] \rightarrow [0]$. This functor induces an isomorphism from Ret onto the subcategory $\Delta_{\min}^{\leq 1} \subset \Delta$ of Notation 10.2.6.16. 05HR

Lemma 10.2.6.19. Let $\mathcal{C}$ be an ∞ -category, let $X_{\bullet}$ be an augmented simplicial object of $\mathcal{C}$, and let $\overline{X} : N_{\bullet}(\Delta_{\min}^{\text{op}}) \rightarrow \mathcal{C}$ be a splitting of $X_{\bullet}$ (in the sense of Definition 10.2.6.3). For every integer n , the following conditions are equivalent: 04TE

- (1) The functor $\overline{X}$ is right Kan extended from the full subcategory $N_{\bullet}(\Delta_{\min}^{\leq n+1})$ of Notation 10.2.6.16.
- (2) The augmented simplicial object $X_{\bullet}$ is n -coskeletal: that is, it is right Kan extended from the subcategory $N_{\bullet}(\Delta_{+}^{\leq n})^{\text{op}}$ (Definition 10.2.5.10).

Proof. For each integer $k \geq -1$, we will show that the following conditions are equivalent:

- (1_k) The functor $\overline{X}$ is right Kan extended from the subcategory $N_{\bullet}(\Delta_{\min}^{\leq n+1})^{\text{op}}$ at the object $[k+1]$.
- (2_k) The functor $X_{\bullet}$ is right Kan extended from the subcategory $N_{\bullet}(\Delta_{+}^{\leq n})^{\text{op}}$ at the object $[k]$.

Let $(\Delta_{+}^{\leq n})_{/[k]}$ denote the fiber product $(\Delta_{+})_{/[k]} \times_{\Delta_{+}} \Delta_{+}^{\leq n}$, and define $(\Delta_{\min}^{\leq n+1})_{/[k+1]}$ similarly. By virtue of Corollary 7.2.2.3, it will suffice to show that the concatenation functor C_{+} induces a right cofinal functor

$$G : N_{\bullet}((\Delta_{+}^{\leq n})_{/[k]}) \rightarrow N_{\bullet}((\Delta_{\min}^{\leq n+1})_{/[k+1]}).$$

This follows from Corollary 7.2.3.7, since the functor G admits a left adjoint F (which carries a morphism $\alpha : [m] \rightarrow [k+1]$ of $\Delta_{\min}$ to the nondecreasing function

$$\{k \in [m] : \alpha(k) > 0\} \xrightarrow{\alpha} \{1 < 2 < \cdots < k\} \simeq [k].$$

$\square$

04TF **Variant 10.2.6.20.** Let n be an integer and let $\mathcal{C}$ be an ∞ -category which is equipped with a functor $T : N_{\bullet}(\Delta_{\min}^{\leq n+1})^{\text{op}} \rightarrow \mathcal{C}$. The following conditions are equivalent:

- (1) The functor T admits a right Kan extension $\bar{F} : N_{\bullet}(\Delta_{\min}^{\text{op}}) \rightarrow \mathcal{C}$.
- (2) The composite functor

$$N_{\bullet}(\Delta_{+}^{\leq n})^{\text{op}} \xrightarrow{C_{+}} N_{\bullet}(\Delta_{\min}^{\leq n+1})^{\text{op}} \xrightarrow{T} \mathcal{C}$$

can be extended to an n -coskeletal augmented simplicial object of $\mathcal{C}$.

Proof. We maintain the notations from the proof of Lemma 10.2.6.19. By virtue of Corollary 7.3.5.8, it will suffice to show that for every integer $k \geq -1$, the following conditions are equivalent:

- (1_k) The diagram

$$N_{\bullet}((\Delta_{\min}^{\leq n+1})_{/[k+1]}) \rightarrow N_{\bullet}(\Delta_{\min}^{\leq n+1}) \xrightarrow{T} \mathcal{C}^{\text{op}}$$

admits a colimit in the ∞ -category $\mathcal{C}^{\text{op}}$.

- (2_k) The diagram

$$N_{\bullet}((\Delta_{+}^{\leq n})_{/[k]}) \xrightarrow{G} N_{\bullet}((\Delta_{\min}^{\leq n+1})_{/[k+1]}) \rightarrow N_{\bullet}(\Delta_{\min}^{\leq n+1}) \xrightarrow{T} \mathcal{C}^{\text{op}}$$

admits a colimit in the ∞ -category $\mathcal{C}^{\text{op}}$.

As in the proof of Lemma 10.2.6.19, the functor G is right cofinal, so the equivalence of (1_k) and (2_k) is a special case of Corollary 7.2.2.10. $\square$

04TG **Proposition 10.2.6.21.** Let $\mathcal{C}$ be an ∞ -category, let n be an integer, let $\text{Fun}'(N_{\bullet}(\Delta_{+}^{\text{op}}), \mathcal{C})$ be the full subcategory of $\text{Fun}(N_{\bullet}(\Delta_{+}^{\text{op}}), \mathcal{C})$ spanned by the n -coskeletal augmented simplicial objects of $\mathcal{C}$, and let $\text{Fun}'(N_{\bullet}(\Delta_{\min}^{\text{op}}), \mathcal{C}) \subseteq \text{Fun}(N_{\bullet}(\Delta_{\min}^{\text{op}}), \mathcal{C})$ be its inverse image. Then precomposition with the concatenation functor C_{+} induces a trivial Kan fibration

$$\theta : \text{Fun}'(N_{\bullet}(\Delta_{\min}^{\text{op}}), \mathcal{C}) \rightarrow \text{Fun}'(N_{\bullet}(\Delta_{\min}^{\leq n+1})^{\text{op}}, \mathcal{C}) \times_{\text{Fun}(N_{\bullet}(\Delta_{+}^{\leq n})^{\text{op}}, \mathcal{C})} \text{Fun}'(N_{\bullet}(\Delta_{+}^{\text{op}}), \mathcal{C}).$$

Proof. Let $\text{Fun}'(N_{\bullet}(\Delta_{+}^{\leq n})^{\text{op}}, \mathcal{C})$ denote the full subcategory of $\text{Fun}(N_{\bullet}(\Delta_{+}^{\leq n})^{\text{op}}, \mathcal{C})$ spanned by those functors which can be extended to n -coskeletal augmented simplicial objects of $\mathcal{C}$,

and define $\text{Fun}'(\mathbf{N}_\bullet(\Delta_{\min}^{\leq n+1})^{\text{op}}, \mathcal{C})$ similarly. We then have a commutative diagram

$$\begin{array}{ccc}
 \text{Fun}'(\mathbf{N}_\bullet(\Delta_{\min}^{\text{op}}), \mathcal{C}) & \longrightarrow & \text{Fun}'(\mathbf{N}_\bullet(\Delta_+^{\text{op}}), \mathcal{C}) \\
 \downarrow & & \downarrow \\
 \text{Fun}'(\mathbf{N}_\bullet(\Delta_{\min}^{\leq n+1})^{\text{op}}, \mathcal{C}) & \longrightarrow & \text{Fun}'(\mathbf{N}_\bullet(\Delta_+^{\leq n})^{\text{op}}, \mathcal{C}) \\
 \downarrow & & \downarrow \\
 \text{Fun}(\mathbf{N}_\bullet(\Delta_{\min}^{\leq n+1})^{\text{op}}, \mathcal{C}) & \longrightarrow & \text{Fun}(\mathbf{N}_\bullet(\Delta_+^{\leq n})^{\text{op}}, \mathcal{C}).
 \end{array}$$

Combining Lemma 10.2.6.19 with Corollary 7.3.6.15, we deduce that the upper vertical maps are trivial Kan fibrations; in particular, the upper half of the diagram is a categorical pullback square (Proposition 4.5.2.22). Variant 10.2.6.20 guarantees that the lower half of the square is a pullback diagram. Since bottom horizontal map is an isofibration of ∞ -categories (Corollary 4.4.5.3), it is a categorical pullback square (Corollary 4.5.2.28). It follows that the outer rectangle is a categorical pullback square (Proposition 4.5.2.19), so that θ is an equivalence of ∞ -categories (Proposition 4.5.2.27). Corollary 4.4.5.3 guarantees that θ is also an isofibration, so it is a trivial Kan fibration (Proposition 4.5.5.20). $\square$

Proof of Proposition 10.2.6.14. Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$ which admits a Čech nerve $\check{\mathbf{C}}_\bullet(X/Y)$. Applying Proposition 10.2.6.21 (in the case $n = 0$), we see that precomposition with the inclusion map

$$\text{Ret}^{\text{op}} \simeq \text{Ret} \simeq \Delta_{\min}^{\leq 1} \hookrightarrow \Delta_{\min}$$

of Example 10.2.6.18 induces a trivial Kan fibration

$$\{\check{\mathbf{C}}_\bullet(X/Y)\} \times_{\text{Fun}(\mathbf{N}_\bullet(\Delta_+^{\text{op}}), \mathcal{C})} \text{Fun}(\mathbf{N}_\bullet(\Delta_{\min}^{\text{op}}), \mathcal{C}) \rightarrow \{f\} \times_{\text{Fun}(\Delta^1, \mathcal{C})} \text{Fun}(\mathbf{N}_\bullet(\text{Ret}), \mathcal{C}).$$

In particular, the left hand side is nonempty if and only if the right hand side is nonempty: that is, the Čech nerve $\check{\mathbf{C}}_\bullet(X/Y)$ splits if and only if f has a right homotopy inverse. $\square$

We close this section by describing an important special class of split simplicial objects.

Construction 10.2.6.22 (Decalage). Let $\mathcal{C}$ be an ∞ -category and let $X_\bullet$ be a simplicial object of $\mathcal{C}$. We let $\text{Dec}_+(X)_\bullet$ denote the augmented simplicial object of $\mathcal{C}$ given by the composition

$$\mathbf{N}_\bullet(\Delta_+^{\text{op}}) \xrightarrow{\mathbf{N}_\bullet(C_+^{\text{op}})} \mathbf{N}_\bullet(\Delta_{\min}^{\text{op}}) \subset \mathbf{N}_\bullet(\Delta^{\text{op}}) \xrightarrow{X_\bullet} \mathcal{C},$$

where C_+ denote the concatenation functor of Remark 10.2.6.2. We will refer to $\text{Dec}_+(X)_\bullet$ as the *augmented decalage* of $X_\bullet$. We let $\text{Dec}(X)_\bullet$ denote the underlying simplicial object of $\text{Dec}_+(X)_\bullet$, given by the composition

$$\mathbf{N}_\bullet(\Delta^{\text{op}}) \xrightarrow{\mathbf{N}_\bullet(C^{\text{op}})} \mathbf{N}_\bullet(\Delta_{\min}^{\text{op}}) \subset \mathbf{N}_\bullet(\Delta^{\text{op}}) \xrightarrow{X_\bullet} \mathcal{C}.$$

We will defer to $\text{Dec}(X)_\bullet$ as the *decalage* of $X_\bullet$.

04SP Remark 10.2.6.23. More informally, the augmented decalage of a simplicial object $X_\bullet$ is given by the formula $\text{Dec}_+(X)_n = X_{n+1}$. Moreover, for every pair of integers $0 \leq i \leq n$, the face and degeneracy operators

$$d_i^n : \text{Dec}_+(X)_n \rightarrow \text{Dec}_+(X)_{n-1} \quad s_i^n : \text{Dec}_+(X)_n \rightarrow \text{Dec}_+(X)_{n+1}$$

coincide with the face and degeneracy operators

$$d_{i+1}^{n+1} : X_{n+1} \rightarrow X_n \quad s_{i+1}^{n+1} : X_{n+1} \rightarrow X_{n+2}.$$

04SQ Example 10.2.6.24. Let X be a simplicial set. Then the decalage $\text{Dec}(X)_\bullet$ can be identified with the disjoint union of coslice constructions $\coprod_x X_{x/}$, where the coproduct is indexed by the collection of all vertices $x \in X$.

04SR Remark 10.2.6.25. Let $X_\bullet$ be a simplicial object of an ∞ -category $\mathcal{C}$. Then the augmented simplicial object $\text{Dec}_+(X)_\bullet$ is split: it admits a splitting given by the diagram

$$\mathbf{N}_\bullet(\Delta_{\min}^{\text{op}}) \subset \mathbf{N}_\bullet(\Delta^{\text{op}}) \xrightarrow{X_\bullet} \mathcal{C}.$$

In particular, Proposition 10.2.6.9 guarantees that $\text{Dec}_+(X)_\bullet$ is a colimit diagram in $\mathcal{C}$: that is, it exhibits the object $X_0 \in \mathcal{C}$ as a geometric realization of the decalage $\text{Dec}(X)_\bullet$.

04SS Remark 10.2.6.26. Let $\iota : \Delta_{\min} \hookrightarrow \Delta$ denote the inclusion functor, and let

$$C : \Delta \rightarrow \Delta_{\min} \quad [n] \mapsto [0] \star [n] = [n+1]$$

denote the concatenation functor of Remark 10.2.6.2. There is a natural transformation $\eta : \text{id}_\Delta \rightarrow \iota \circ C$, which carries each object $[n] \in \Delta$ to the inclusion map

$$[n] \hookrightarrow [n+1] \quad i \mapsto i+1.$$

If $X_\bullet$ is a simplicial object of an ∞ -category $\mathcal{C}$, then composition with η determines a natural transformation of simplicial objects $T_\bullet : \text{Dec}(X)_\bullet \rightarrow X_\bullet$, given termwise by the face operator $\text{Dec}(X)_n = X_{n+1} \xrightarrow{d_0^{n+1}} X_n$.

The natural transformation η is the unit of an adjunction between ι and C ; it admits a compatible counit $\epsilon : C \circ \iota \rightarrow \text{id}_{\Delta_{\min}}$, which carries each object $[n]$ to the quotient map

$$[n+1] \twoheadrightarrow [n] \quad i \mapsto \max(0, i-1).$$

We therefore have a commutative diagram

$$\begin{array}{ccc} & C \circ \iota \circ C & \\ \eta \circ \text{id}_C \nearrow & & \searrow \text{id}_C \circ \epsilon \\ C & \xrightarrow{\text{id}_C} & C \end{array} \quad (10.4) \quad 04\text{ST}$$

in the functor category $\text{Fun}(\Delta, \Delta_{\min})$. If $\bar{X}$ is a splitting of the simplicial object $X_{\bullet}$, then precomposition with (10.4) determines a commutative diagram

$$\begin{array}{ccc} & \text{Dec}(X)_{\bullet} & \\ h_{\bullet} \nearrow & & \searrow T_{\bullet} \\ X_{\bullet} & \xrightarrow{\text{id}} & X_{\bullet} \end{array}$$

in the ∞ -category of simplicial objects $\text{Fun}(\mathbf{N}_{\bullet}(\Delta^{\text{op}}), \mathcal{C})$. Here $h_{\bullet}$ is given termwise by the extra degeneracy map $h_n : X_n \rightarrow X_{n+1} = \text{Dec}(X)_n$ appearing in Remark 10.2.6.4. In particular, if $X_{\bullet}$ is a split simplicial object of $\mathcal{C}$, then it is a retract of the decalage $\text{Dec}(X)_{\bullet}$.

Warning 10.2.6.27. Let $X_{\bullet}$ be a simplicial object of an ∞ -category $\mathcal{C}$. It follows from Remark 10.2.6.26 that every splitting of $X_{\bullet}$ determines a right homotopy inverse to the comparison map $T_{\bullet} : \text{Dec}(X)_{\bullet} \rightarrow X_{\bullet}$. Beware that, in general, not every right homotopy inverse can be obtained in this way. For example, suppose that $\mathcal{C}$ is (the nerve of) an ordinary category. Unwinding the definitions, we see that a morphism of simplicial objects from $X_{\bullet}$ to $\text{Dec}(X)_{\bullet}$ is given by a collection of morphisms $h_n : X_n \rightarrow \text{Dec}(X)_n = X_{n+1}$ which satisfy the identities

$$d_i^{n+1} \circ h_n = h_{n-1} \circ d_{i-1}^n \quad s_i^{n+1} \circ h_n = h_{n+1} \circ s_{i-1}^n$$

for $0 < i \leq n+1$. Moreover, $h_{\bullet}$ is a right inverse of $T_{\bullet}$ if and only if it satisfies the further identity $d_0^{n+1} \circ h_n = \text{id}_{X_n}$ for each $n \geq 0$. However, $h_{\bullet}$ arises from a splitting of the simplicial object $X_{\bullet}$ only if it also satisfies the identities $s_0^{n+1} \circ h_n = h_{n+1} \circ h_n$; see Exercise 10.2.6.5 (compare with Warning 10.2.6.8).

10.3 Regular ∞ -Categories

04TM Let X and Y be sets and let $f : X \rightarrow Y$ be a function. Recall that the *image* of f is the subset $\operatorname{im}(f) \subseteq Y$ consisting of those elements $y \in Y$ satisfying $y = f(x)$ for some element $x \in X$. Writing i for the inclusion of $\operatorname{im}(f)$ into Y , the function f then factors as a composition

$$X \xrightarrow{f_0} \operatorname{im}(f) \xrightarrow{i} Y.$$

This factorization admits a more abstract characterization: it is determined (up to unique isomorphism) by the requirements that i is injective (that is, it is a monomorphism in the category of sets) and that f_0 is surjective (that is, it is an epimorphism in the category of sets).

The construction $f \mapsto \operatorname{im}(f)$ has counterparts in many other categories. For example, every homomorphism of commutative rings $f : R \rightarrow S$ has a tautological factorization

$$R \xrightarrow{f_0} \operatorname{im}(f) \xrightarrow{i} S,$$

which is again characterized (up to unique isomorphism) by the requirements that i is injective and that f_0 is surjective. Here the first demand is equivalent to the condition that i is a monomorphism in the category of commutative rings. However, the second demand is more subtle. Every surjective ring homomorphism is an epimorphism in the category of commutative rings, but the converse is false in general.

04TN **Example 10.3.0.1.** Let $\mathbf{Q}$ denote the field of rational numbers, let $\mathbf{Z} \subseteq \mathbf{Q}$ denote the ring of integers, and let $f : \mathbf{Z} \hookrightarrow \mathbf{Q}$ denote the inclusion map. Then f is both a monomorphism and an epimorphism in the category of commutative rings. Consequently, the ring homomorphism f admits (at least) two factorizations as an epimorphism followed by a monomorphism, given by the diagrams

$$\mathbf{Z} \xrightarrow{\operatorname{id}} \mathbf{Z} \xrightarrow{f} \mathbf{Q} \quad \mathbf{Z} \xrightarrow{f} \mathbf{Q} \xrightarrow{\operatorname{id}} \mathbf{Q}.$$

To address the phenomenon described in Example 10.3.0.1, it is convenient to modify the definition of epimorphism.

04TP **Definition 10.3.0.2.** Let $\mathcal{C}$ be a category which admits pullbacks. We will say that a morphism $f : X \rightarrow Y$ of $\mathcal{C}$ is a *regular epimorphism* if it exhibits Y as a coequalizer of the pair of projection maps $\pi_0, \pi_1 : X \times_Y X \rightarrow X$.

04TQ **Remark 10.3.0.3.** Let $\mathcal{C}$ be a category which admits pullbacks and let $f : X \rightarrow Y$ be a morphism in $\mathcal{C}$. Then f is an epimorphism if and only if, for every object $Z \in \mathcal{C}$, the function

$$\theta_Z : \operatorname{Hom}_{\mathcal{C}}(Y, Z) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Z) \quad g \mapsto g \circ f$$

is injective. The condition that f is a regular epimorphism is (in general) stronger: it requires also that the image of θ_Z is the collection of morphisms $h : X \rightarrow Z$ which satisfy the identity $h \circ \pi_0 = h \circ \pi_1$; here π_0 and π_1 denote the projection maps from $X \times_Y X$ to X .

Example 10.3.0.4. Let $\mathcal{C} = \mathbf{Set}$ be the category of sets and let $f : X \twoheadrightarrow Y$ be an 04TR epimorphism in $\mathcal{C}$: that is, a surjective function. Then f is a regular epimorphism: that is, it exhibits Y as a quotient of the equivalence relation $\equiv_f$, defined by the requirement

$$(x \equiv_f x') \Leftrightarrow (f(x) = f(x')).$$

Exercise 10.3.0.5. Let $f : R \rightarrow S$ be a homomorphism of commutative rings. Show that f 04TS is a regular epimorphism (in the category of commutative rings) if and only if it is surjective (as a map of sets). In particular, the inclusion map $\mathbf{Z} \hookrightarrow \mathbf{Q}$ of Example 10.3.0.1 is an epimorphism in the category of commutative rings which is not regular.

Let $\mathcal{C}$ be a category which admits pullbacks and let $f : X \rightarrow Y$ be a morphism in $\mathcal{C}$. We will say that an object $Y_0 \in \mathcal{C}$ is an *image of f* if the morphism f factors as a composition

$$X \xrightarrow{f_0} Y_0 \xrightarrow{i} Y,$$

where i is a monomorphism and f_0 is a regular epimorphism. It is not difficult to show that if such a factorization exists, then it is uniquely determined up to (canonical) isomorphism: for example, the object Y_0 can be recovered as the coequalizer of the pair of projection maps $X \times_Y X \rightrightarrows X$. To emphasize the uniqueness, we will typically denote the object Y_0 by $\mathrm{im}(f)$ and refer to it as *the image of f* . This motivates the following:

Definition 10.3.0.6. Let $\mathcal{C}$ be a category. We say that $\mathcal{C}$ is *regular* if it satisfies the following 04TT conditions:

- (1) The category $\mathcal{C}$ admits finite limits (in particular, it admits pullbacks).
- (2) Every morphism $f : X \rightarrow Y$ of $\mathcal{C}$ has an image: that is, we can write f as a composition

$$X \xrightarrow{f_0} Y_0 \xrightarrow{i} Y$$

where i is a monomorphism and f_0 is a regular epimorphism.

- (3) The collection of regular epimorphisms is stable under the formation of pullbacks. That is, for every pullback diagram

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow f' & & \downarrow f \\ Y' & \longrightarrow & Y \end{array}$$

in the category $\mathcal{C}$, if f is a regular epimorphism, then f' is also a regular epimorphism.

04TU **Example 10.3.0.7.** The axioms of Definition 10.3.0.6 tend to be satisfied by any category $\mathcal{C}$ whose objects can be described as “sets with algebraic structure.” For example:

- The category of sets is regular.
- The category of groups is regular.
- The category of abelian groups is regular.
- The category of associative rings is regular.
- The category of commutative rings is regular.

04TV **Example 10.3.0.8.** Let $\mathcal{C}$ be the category of partially ordered sets (with morphisms given by nondecreasing functions). Then $\mathcal{C}$ is not regular: it satisfies conditions (1) and (2) of Definition 10.3.0.6, but does not satisfy condition (3) (see Exercise 10.3.2.16).

Our goal in this section is to extend Definition 10.3.0.6 to the setting of ∞ -categories. The first step is to find an appropriate ∞ -categorical counterpart for the notion of regular epimorphism. Let $\mathcal{C}$ be an ∞ -category which admits pullbacks. Then, to every morphism $f : X \rightarrow Y$ of $\mathcal{C}$, one can associate a diagram

$$04TW \quad X \times_Y X \underset{\pi_1}{\overset{\pi_0}{\rightrightarrows}} X \xrightarrow{f} Y. \quad (10.5)$$

If $\mathcal{C}$ is (the nerve of) an ordinary category, then f is a regular epimorphism if and only if (10.5) is a coequalizer diagram. In the ∞ -categorical setting, this condition is almost never satisfied (even if f is an isomorphism). To guarantee that a morphism $g : X \rightarrow Z$ factors (up to homotopy) through f , it is typically not enough to know that $g \circ \pi_0$ is homotopic to $g \circ \pi_1$: one needs a homotopy satisfying further coherence conditions, whose formalization involves iterated fiber products $X \times_Y X \times_Y \cdots \times_Y X$. Recall that the collection of all such fiber products can be organized into an augmented simplicial object $\check{C}_\bullet(X/Y)$ called the *Čech nerve* of f (Definition 10.2.5.4), which we display informally as

$$\cdots \rightrightarrows X \times_Y X \times_Y X \rightrightarrows X \times_Y X \underset{\pi_1}{\overset{\pi_0}{\rightrightarrows}} X \longrightarrow Y.$$

We will say that f is a *quotient morphism* if $\check{C}_\bullet(X/Y)$ is a colimit diagram in the ∞ -category $\mathcal{C}$.

04TX **Remark 10.3.0.9.** In §10.3.2, we adopt a slightly different definition of quotient morphism (Definition 10.3.2.1), which makes sense in any ∞ -category $\mathcal{C}$ (that is, we do not need to assume that $\mathcal{C}$ admits pullbacks). Our definition is formulated using the language of *sieves*, which we review in §10.3.1. When $\mathcal{C}$ admits pullbacks, the sieve-theoretic definition reduces to the requirement that $\check{C}_\bullet(X/Y)$ is a colimit diagram (see Proposition 10.3.2.4).

Warning 10.3.0.10. Let $\mathcal{C} = \mathbf{N}_\bullet(\mathcal{C}_0)$ be the nerve of an ordinary category $\mathcal{C}_0$, and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. Then f is a quotient morphism if and only if it is a regular epimorphism in $\mathcal{C}_0$, in the sense of Definition 10.3.0.2 (see Corollary 10.3.2.7). In particular, every quotient morphism in $\mathcal{C}$ is an epimorphism. Beware that, if $\mathcal{C}$ is not assumed to be the nerve of an ordinary category, then the analogous statement is false: quotient morphisms in $\mathcal{C}$ are usually not epimorphisms (that is, they are not monomorphisms when viewed as morphisms in the opposite ∞ -category $\mathcal{C}^{\text{op}}$). See Warning 10.3.2.10).

Let $\mathcal{C}$ be an ∞ -category containing a morphism $f : X \rightarrow Y$. We will say that an object $Y_0 \in \mathcal{C}$ is an *image of f* if there exists a diagram

$$\begin{array}{ccc} & Y_0 & \\ f_0 \nearrow & & \searrow i \\ X & \xrightarrow{f} & Y, \end{array}$$

where f_0 is a quotient morphism and i is a monomorphism (Definition 10.3.3.1). In §10.3.3, we will show that if such a diagram exists, then it is unique up to isomorphism (in fact, up to a contractible space of choices: see Proposition 10.3.3.14). Following our discussion of the classical case, we will typically denote the object Y_0 by $\text{im}(f)$ and refer to it as the *image* of the morphism f (Notation 10.3.3.12).

Let $\mathcal{C}$ be an ∞ -category which admits pullbacks. Beware that, in general, the collection of quotient morphisms in $\mathcal{C}$ is not closed under pullback (see Exercise 10.3.2.16). We say that a morphism $f : X \rightarrow Y$ in $\mathcal{C}$ is a *universal quotient morphism* if, for every pullback diagram

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow f' & & \downarrow f \\ Y' & \longrightarrow & Y, \end{array}$$

the morphism f' is a quotient morphism. In §10.3.4, we extend this definition to the setting of an ∞ -category $\mathcal{C}$ which does not necessarily admit pullbacks (see Definition 10.3.4.1 and Corollary 10.3.4.7) and study its properties. The notion of universal quotient morphism is in some respects better behaved than the notion of quotient morphism: for example, the collection of universal quotient morphisms is always closed under composition (Proposition 10.3.4.12), while the collection of quotient morphisms need not be (Exercise 10.3.2.15).

Armed with a good theory of quotient morphisms, we can formulate an ∞ -categorical analogue of Definition 10.3.0.6. We say that an ∞ -category $\mathcal{C}$ is *regular* if it satisfies the following axioms (Definition 10.3.5.1):

- (1) The ∞ -category $\mathcal{C}$ admits finite limits.
- (2) Every morphism $f : X \rightarrow Y$ of $\mathcal{C}$ has an image: that is, we can write f as a composition of a quotient morphism $X \twoheadrightarrow Y_0$ with a monomorphism $Y_0 \hookrightarrow Y$.
- (3) The collection of quotient morphisms in $\mathcal{C}$ is stable under pullback: that is, every quotient morphism is a universal quotient morphism.

In §10.3.5, we discuss various formulations of this definition and give some examples of regular ∞ -categories. In particular, we show that the ∞ -category of spaces $\mathcal{S}$ is regular (Corollary 10.3.5.6) and that the collection of regular ∞ -categories is closed under the formation of slice constructions (Proposition 10.3.5.9) and left exact localization (Proposition 10.3.5.19).

10.3.1 Sieves

04TZ Let $\mathcal{C}$ be a category. Recall that a *sieve on $\mathcal{C}$* is a full subcategory $\mathcal{C}^0 \subseteq \mathcal{C}$ satisfying the following condition:

- If $f : X \rightarrow Y$ is a morphism of $\mathcal{C}$ and Y belongs to the subcategory $\mathcal{C}^0$, then X also belongs to the subcategory $\mathcal{C}^0$.

This condition has a counterpart in the setting of ∞ -categories.

04U0 **Definition 10.3.1.1.** Let $\mathcal{C}$ be a simplicial set. A *sieve on $\mathcal{C}$* is a simplicial subset $\mathcal{C}^0 \subseteq \mathcal{C}$ for which the inclusion map $\mathcal{C}^0 \hookrightarrow \mathcal{C}$ is a right fibration.

04U1 **Example 10.3.1.2.** Let $\mathcal{C}$ be a simplicial set. Then the simplicial subsets $\emptyset, \mathcal{C} \subseteq \mathcal{C}$ are sieves on $\mathcal{C}$.

04U2 **Remark 10.3.1.3** (Base Change). Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a morphism of simplicial sets, and let $\mathcal{D}^0 \subseteq \mathcal{D}$ be a sieve on $\mathcal{D}$. Then the inverse image $\mathcal{C}^0 = F^{-1}(\mathcal{D}^0)$ is a sieve on $\mathcal{C}$.

04U3 **Remark 10.3.1.4** (Transitivity). Let $\mathcal{C}$ be a simplicial set containing simplicial subsets $\mathcal{C}^1 \subseteq \mathcal{C}^0 \subseteq \mathcal{C}$, where $\mathcal{C}^0$ is a sieve on $\mathcal{C}$. Then $\mathcal{C}^1$ is a sieve on $\mathcal{C}^0$ if and only if it is a sieve on $\mathcal{C}$.

04U4 **Proposition 10.3.1.5.** Let $\mathcal{C}$ be a simplicial set. Then a simplicial subset $\mathcal{C}^0 \subseteq \mathcal{C}$ is a sieve if and only if it satisfies the following condition:

- (*) Let $\sigma : \Delta^n \rightarrow \mathcal{C}$ be an n -simplex of $\mathcal{C}$. If the final vertex $\sigma(n)$ is contained in $\mathcal{C}^0$, then σ is contained in $\mathcal{C}^0$.

Proof. For every integer $n \geq 0$, the inclusion map $\{n\} \hookrightarrow \Delta^n$ is right anodyne (Example 4.3.7.11). If the inclusion map $\iota : \mathcal{C}^0 \hookrightarrow \mathcal{C}$ is a right fibration, then condition (*) is a special

case of Proposition 4.2.4.5. Conversely, suppose that condition $(*)$ is satisfied, and let $\sigma : \Delta^n \rightarrow \mathcal{C}$ be an n -simplex of $\mathcal{C}$. For every integer $0 < i \leq n$, the horn Λ_i^n contains the final vertex $\{n\} \subseteq \Delta^n$. Consequently, if the restriction $\sigma|_{\Lambda_i^n}$ factors (uniquely) through ι , then condition $(*)$ guarantees that σ factors (uniquely) through ι . Allowing n and i to vary, we conclude that ι is a right fibration. $\square$

Corollary 10.3.1.6. *Let $\mathcal{C}$ be an ∞ -category and let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a simplicial subset. Then $\mathcal{C}^0$ is a sieve on $\mathcal{C}$ if and only if it is a full subcategory of $\mathcal{C}$ which satisfies the following condition:* 04U5

$(*)$ *If $f : X \rightarrow Y$ is a morphism of $\mathcal{C}$ and Y belongs to the subcategory $\mathcal{C}^0$, then X also belongs to the subcategory $\mathcal{C}^0$.*

Proof. By definition, $\mathcal{C}^0$ is a sieve on $\mathcal{C}$ if and only if the inclusion map $\iota : \mathcal{C}^0 \hookrightarrow \mathcal{C}$ is a right fibration. In particular, this guarantees that ι is an inner fibration, so that $\mathcal{C}^0$ is a subcategory of $\mathcal{C}$. It also guarantees that a morphism $f : X \rightarrow Y$ is contained in $\mathcal{C}^0$ if and only if the object Y is contained in $\mathcal{C}^0$, so that the subcategory $\mathcal{C}^0 \subseteq \mathcal{C}$ is full and satisfies $(*)$. Conversely, if $\mathcal{C}^0 \subseteq \mathcal{C}$ is a full subcategory satisfying condition $(*)$, then ι satisfies the criterion of Proposition 10.3.1.5 and is therefore a right fibration. $\square$

Example 10.3.1.7. Let $\mathcal{C}$ be a category and let S be a simplicial subset of $N_\bullet(\mathcal{C})$. Then S is a sieve on $N_\bullet(\mathcal{C})$ (in the sense of Definition 10.3.1.1) if and only if it has the form $N_\bullet(\mathcal{C}^0)$, where $\mathcal{C}^0$ is sieve on $\mathcal{C}$ (in the usual category-theoretic sense). 04U6

Corollary 10.3.1.8. *Let $\mathcal{C}$ be an ∞ -category and let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a sieve. Then $\mathcal{C}^0$ is a replete full subcategory of $\mathcal{C}$. In particular, $\mathcal{C}^0$ is an ∞ -category.* 04U7

Remark 10.3.1.9. Let $\mathcal{C}$ be an ∞ -category, let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a sieve, and let $f : K \rightarrow \mathcal{C}^0$ be a diagram. If the simplicial set K is nonempty, then the inclusion map $\mathcal{C}_{/f}^0 \hookrightarrow \mathcal{C}_{/f}$ is an isomorphism. In particular, an extension $\bar{f} : K^\triangleleft \rightarrow \mathcal{C}^0$ is a limit diagram in the ∞ -category $\mathcal{C}^0$ if and only if it is a limit diagram in $\mathcal{C}$. See Corollary 9.6.1.21 for a more general statement. 04U8

Remark 10.3.1.10. Let $\mathcal{C}$ be an ∞ -category, let X be an object of $\mathcal{C}$, and let $\mathcal{C}^0 \subseteq \mathcal{C}$ be the sieve generated by X . Then the projection map $U : \mathcal{C}_{/X} \rightarrow \mathcal{C}$ factors through a functor $U^0 : \mathcal{C}_{/X} \rightarrow \mathcal{C}^0$. Moreover, the following conditions are equivalent: 04V5

- (1) The object $X \in \mathcal{C}$ is subterminal (see Definition 9.6.2.2).
- (2) The functor U^0 is a trivial Kan fibration.
- (3) The functor U^0 is an equivalence of ∞ -categories.

The equivalence (1) $\Leftrightarrow$ (2) is a reformulation of Remark 9.6.2.14. Note that U^0 is a pullback of U , and therefore a right fibration (Proposition 4.3.6.1). In particular, U^0 is an isofibration (Example 4.4.1.11), so the equivalence (2) $\Leftrightarrow$ (3) follows from Proposition 4.5.5.20.

04U9 Example 10.3.1.11. Let $\mathcal{C}$ be an ∞ -category, let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a sieve, and let X be an object of $\mathcal{C}^0$. If $C_\bullet$ is any simplicial object of $\mathcal{C}$ satisfying $C_0 = X$, then $C_\bullet$ can also be regarded as a simplicial object of $\mathcal{C}^0$. Applying Remark 10.3.1.9, we deduce that $C_\bullet$ is a Čech nerve of X in the ∞ -category $\mathcal{C}^0$ if and only if it is a Čech nerve of X in the ∞ -category $\mathcal{C}$ (see Definition 10.2.4.1).

04UA Proposition 10.3.1.12. Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a morphism of simplicial sets. The following conditions are equivalent:

- (1) The morphism U restricts to an isomorphism of $\mathcal{E}$ with a sieve $\mathcal{C}^0 \subseteq \mathcal{C}$.
- (2) The morphism U is a right covering map (Definition 4.2.3.8) and, for every vertex $C \in \mathcal{C}$, the fiber $U^{-1}\{C\}$ has at most one element.

Proof. The implication (1) $\Rightarrow$ (2) follows from Example 4.2.3.12. Conversely, suppose that condition (2) is satisfied, and let $\mathrm{h}\mathcal{C}$ denote the homotopy category of $\mathcal{C}$. Our assumption that U is a right covering map guarantees the existence of a pullback square

$$\begin{array}{ccc} \mathcal{E} & \xrightarrow{U} & N_\bullet(\int^{\mathrm{h}\mathcal{C}} \mathcal{F}) \\ \downarrow & & \downarrow \\ \mathcal{C} & \longrightarrow & N_\bullet(\mathrm{h}\mathcal{C}) \end{array}$$

where $\mathcal{F} : \mathrm{h}\mathcal{C}^{\mathrm{op}} \rightarrow \mathrm{Set}$ is the contravariant homotopy transport representation of $\mathcal{C}$, given concretely by the formula $\mathcal{F}(C) = U^{-1}\{C\}$ (see Corollary 5.2.7.4). Our assumption that each of the sets $\mathcal{F}(C)$ has at most one element guarantees that the right vertical map induces an isomorphism from $\int^{\mathrm{h}\mathcal{C}} \mathcal{F}$ to the sieve $\mathcal{D} \subseteq \mathrm{h}\mathcal{C}$ spanned by those objects C for which the fiber $U^{-1}\{C\}$ is nonempty. Condition (1) now follows from Example 10.3.1.7 and Remark 10.3.1.3. $\square$

04UB Corollary 10.3.1.13. Let $\mathcal{C}$ be a simplicial set and let $\mathcal{D} = \mathrm{h}\mathcal{C}$ denote its homotopy category. Then the construction $(\mathcal{D}^0 \subseteq \mathcal{D}) \mapsto N_\bullet(\mathcal{D}^0) \times_{N_\bullet(\mathcal{D})} \mathcal{C}$ induces a bijection

$$\{\text{Sieves } \mathcal{D}^0 \subseteq \mathcal{D}\} \rightarrow \{\text{Sieves } \mathcal{C}^0 \subseteq \mathcal{C}\}.$$

04UC Remark 10.3.1.14. Let $\mathcal{C}$ be a simplicial set. Then the collection of sieves on $\mathcal{C}$ is closed under the formation of intersections. In particular, for every vertex $X \in \mathcal{C}$, there is a

smallest sieve $\mathcal{C}^0 \subseteq \mathcal{C}$ containing X . We will refer to $\mathcal{C}^0$ as the *sieve generated by X* . If $\mathcal{C}$ is an ∞ -category, then $\mathcal{C}^0$ admits a more explicit description: it is the full subcategory of $\mathcal{C}$ spanned by those objects C for which there exists a morphism $f : C \rightarrow X$.

Remark 10.3.1.15. Let $\mathcal{C}$ be an ∞ -category, let X be an object of $\mathcal{C}$, and let $\mathcal{C}^0 \subseteq \mathcal{C}$ be the sieve generated by X (Remark 10.3.1.14): that is, the full subcategory of $\mathcal{C}$ spanned by those objects C for which the morphism space $\mathrm{Hom}_{\mathcal{C}}(C, X)$ is nonempty. Then X is a subterminal object of $\mathcal{C}$ (in the sense of Definition 9.6.2.2) if and only if it is a final object of $\mathcal{C}^0$ (in the sense of Definition 4.6.7.1). 04UZ

Remark 10.3.1.16. Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. Suppose that $\mathcal{C}$ admits finite limits, so that f admits a Čech nerve $\check{C}(X/Y)_{\bullet}$ (Proposition 10.2.5.6). If Y is a subterminal object of $\mathcal{C}$, then the underlying simplicial object of $\check{C}(X/Y)_{\bullet}$ is also a Čech nerve of the object X . This follows by combining Remark 10.3.1.10 with Example 10.3.1.11. 04V6

Remark 10.3.1.17. Let $\mathcal{C}$ be an ∞ -category containing a 2-simplex 04W3

$$\begin{array}{ccc} & Y & \\ f \nearrow & & \searrow g \\ X & \xrightarrow{h} & Z, \end{array} \quad (10.6) \quad \text{04W4}$$

where g is a monomorphism. Suppose that $\mathcal{C}$ admits pullbacks, so that the morphisms f and h admit Čech nerves $\check{C}_{\bullet}(X/Y)$ and $\check{C}_{\bullet}(X/Z)$ (Proposition 10.2.5.6). Then the underlying simplicial objects of $\check{C}_{\bullet}(X/Y)$ and $\check{C}_{\bullet}(X/Z)$ are canonically isomorphic. To see this, let us regard (10.6) as morphism $\tilde{f} : \tilde{X} \rightarrow \tilde{Y}$ in the slice ∞ -category $\mathcal{C}_{/Z}$. Since the forgetful functor $\mathcal{C}_{/Z} \rightarrow \mathcal{C}$ preserves pullbacks (Corollary 7.1.7.5), we can identify $\check{C}_{\bullet}(X/Y)$ with the image of $\check{C}_{\bullet}(\tilde{X}/\tilde{Y})$. The desired result now follows by applying Example 10.3.1.16 to the object $\tilde{Y} \in \mathcal{C}_{/Z}$ (which is subterminal by virtue of Remark 9.6.4.16).

It will often be convenient to work with a variant Definition 10.3.1.1.

Definition 10.3.1.18. Let $\mathcal{C}$ be an ∞ -category and let Y be an object of $\mathcal{C}$. A *sieve on Y* is a sieve on the slice ∞ -category $\mathcal{C}_{/Y}$; that is, a full subcategory $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ satisfying the following condition: 04UD

(*) For every 2-simplex

$$\begin{array}{ccc} X' & \xrightarrow{\quad} & X \\ & f' \searrow & \swarrow f \\ & Y & \end{array}$$

in the ∞ -category $\mathcal{C}$, if f is contained in the subcategory $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$, then f' is also contained in $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$.

04UE Example 10.3.1.19. Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. By virtue of Remark 10.3.1.14, there is a smallest sieve $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ on the object Y which contains the morphism f . We will refer to $\mathcal{C}_{/Y}^0$ as the *sieve generated by f* . Concretely, a morphism $e : C \rightarrow Y$ belongs to the sieve $\mathcal{C}_{/Y}^0$ if and only if there exists a commutative diagram

$$\begin{array}{ccc} C & \xrightarrow{\quad} & X \\ & \searrow e & \swarrow f \\ & Y & \end{array}$$

in the ∞ -category $\mathcal{C}$. Stated more informally, a morphism e belongs to the sieve $\mathcal{C}_{/Y}^0$ if and only if it factors through f .

04UF Remark 10.3.1.20. Let $\mathcal{C}$ be an ∞ -category and let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ be a sieve on an object Y . Then $\mathcal{C}_{/Y}^0$ coincides with $\mathcal{C}_{/Y}$ if and only if it contains the identity morphism $\text{id}_Y : Y \rightarrow Y$. In particular, if $\mathcal{C}_{/Y}^0$ is the sieve generated by a morphism $f : X \rightarrow Y$ (Example 10.3.1.19), then $\mathcal{C}_{/Y}^0 = \mathcal{C}_{/Y}$ if and only if the morphism f admits a right homotopy inverse $s : Y \rightarrow X$.

04UG Remark 10.3.1.21. Let $\mathcal{C}$ be an ∞ -category, let Y be an object of $\mathcal{C}$, and let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ be a sieve on Y . The condition that a morphism $f : X \rightarrow Y$ belongs to $\mathcal{C}_{/Y}^0$ depends only on the isomorphism class of f as an object of the ∞ -category $\mathcal{C}_{/Y}$. In particular, if X is fixed, then the condition that f belongs to $\mathcal{C}_{/Y}^0$ depends only on the homotopy class $[f] \in \text{Hom}_{\text{hc}}(X, Y)$.

We have the following variant of Corollary 10.3.1.13:

04UH Proposition 10.3.1.22. Let $\mathcal{C}$ be an ∞ -category, let $\mathcal{D} = \text{h}\mathcal{C}$ be its homotopy category, and let Y be an object of $\mathcal{C}$ (which we also regard as an object of $\mathcal{D}$). Then the construction $(\mathcal{D}_{/Y}^0 \subseteq \mathcal{D}_{/Y}) \mapsto \mathbf{N}_{\bullet}(\mathcal{D}_{/Y}^0) \times_{\mathbf{N}_{\bullet}(\mathcal{D}_{/Y})} \mathcal{C}_{/Y}$ induces a bijection

$$\{\text{Sieves } \mathcal{D}_{/Y}^0 \subseteq \mathcal{D}_{/Y}\} \xrightarrow{\sim} \{\text{Sieves } \mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}\}.$$

04UJ Warning 10.3.1.23. Proposition 10.3.1.22 is not a special case of Corollary 10.3.1.13, because the slice category $\mathcal{D}_{/Y}$ is usually not equivalent to the homotopy category of $\mathcal{C}_{/Y}$.

Proof of Proposition 10.3.1.22. Let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ be a sieve on the ∞ -category $\mathcal{C}_{/Y}$. We wish to show that there is a unique sieve $\mathcal{D}_{/Y}^0 \subseteq \mathcal{D}_{/Y}$ with the following property: a morphism $f : X \rightarrow Y$ belongs to the sieve $\mathcal{C}_{/Y}^0$ if and only if the homotopy class $[f]$ belongs to the sieve $\mathcal{D}_{/Y}^0$. The uniqueness assertion is immediate. To prove existence, we define $\mathcal{D}_{/Y}^0$ to be the

full subcategory of $\mathcal{D}_{/Y}$ spanned by those homotopy classes $[f] : X \rightarrow Y$ such that f belongs to $\mathcal{C}_{/Y}^0$; by virtue of Remark 10.3.1.21, this condition depends only on the homotopy class $[f]$ and not on the choice of representative f . To complete the proof, it will suffice to show that the subcategory $\mathcal{D}_{/Y}^0 \subseteq \mathcal{D}_{/Y}$ is a sieve. Suppose we are given a commutative diagram

$$\begin{array}{ccc} X' & \xrightarrow{\quad} & X \\ & \searrow [f'] & \swarrow [f] \\ & Y & \end{array} \quad (10.7)$$

in the homotopy category $\mathcal{D} = \mathbf{h}\mathcal{C}$. We wish to show that if $[f]$ belongs to $\mathcal{D}_{/Y}^0$, then $[f']$ also belongs to $\mathcal{D}_{/Y}^0$. This follows from our assumption that $\mathcal{C}_{/Y}^0$ is a sieve on Y , since (10.7) can be lifted to a 2-simplex in the ∞ -category $\mathcal{C}$. $\square$

Notation 10.3.1.24 (Pullback Sieves). Let $\mathcal{C}$ be an ∞ -category, let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$, and let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ be a sieve on the object Y . We let $f^*(\mathcal{C}_{/Y}^0)$ denote the full subcategory of $\mathcal{C}_{/X}$ spanned by those objects $e : C \rightarrow X$ for which the composition $(f \circ e) : C \rightarrow Y$ belongs to $\mathcal{C}_{/Y}^0$. By virtue of Remark 10.3.1.21, this condition is independent of the choice of composition $f \circ e$. The subcategory $f^*(\mathcal{C}_{/Y}^0)$ is a sieve on the object X , which we will refer to as the *pullback of $\mathcal{C}_{/Y}^0$ along the morphism f* . 04UL

Example 10.3.1.25. Let $\mathcal{C}$ be an ∞ -category containing a pullback diagram 04UM

$$\begin{array}{ccc} X' & \xrightarrow{\quad} & X \\ \downarrow f' & & \downarrow f \\ Y' & \xrightarrow{\quad u \quad} & Y, \end{array}$$

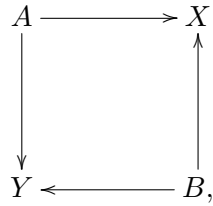

and let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ be the sieve on Y generated by the morphism f . Then the pullback $u^*(\mathcal{C}_{/Y}^0)$ is the sieve on Y' generated by the morphism f' . In other words, a morphism $[v] : C \rightarrow X'$ in the homotopy category $\mathbf{h}\mathcal{C}$ factors through $[f']$ if and only if the composite morphism $[u] \circ [v]$ factors through $[f]$ (see Warning 7.6.2.3).

Let $\mathcal{C}$ be an ∞ -category. Recall that a full subcategory $\mathcal{C}^0 \subseteq \mathcal{C}$ is *dense* if the identity functor $\mathrm{id}_{\mathcal{C}} : \mathcal{C} \rightarrow \mathcal{C}$ is left Kan extended from $\mathcal{C}^0$ (Definition 8.4.1.5). We now consider a slight variant of this condition.

Definition 10.3.1.26. Let $\mathcal{C}$ be an ∞ -category and let X be an object of $\mathcal{C}$. We say that a sieve $\mathcal{C}_{/X}^0 \subseteq \mathcal{C}_{/X}$ on X is *dense* if the forgetful functor $\mathcal{C}_{/X} \rightarrow \mathcal{C}$ is left Kan extended from $\mathcal{C}_{/X}^0$. 04UN

04UP **Warning 10.3.1.27.** The terminology of Definition 10.3.1.26 has the potential to create confusion. Since the forgetful functor $\mathcal{C}_{/X} \rightarrow \mathcal{C}$ creates colimits (Proposition 7.1.4.21), a sieve $\mathcal{C}_{/X}^0 \subseteq \mathcal{C}_{/X}$ which is dense in the sense of Definition 10.3.1.26 is also dense when regarded as a full subcategory of $\mathcal{C}_{/X}$ (in the sense of Definition 8.4.1.5). Beware that the converse is false in general (Example 10.3.1.28). However, it is true if $\mathcal{C}$ admits finite products (Proposition 10.3.1.29).

04UQ **Example 10.3.1.28.** Let $\mathcal{C}$ be the 1-dimensional simplicial set associated to the directed graph depicted in the diagram

and let $\mathcal{C}_{/X}^0 \subseteq \mathcal{C}_{/X}$ be the sieve spanned by the objects A and B . Then $\mathcal{C}_{/X}^0$ is dense when regarded as a full category of $\mathcal{C}_{/X}$ (in the sense of Definition 8.4.1.5), but not when regarded as a sieve on X (in the sense of Definition 10.3.1.26).

04UR **Proposition 10.3.1.29.** *Let $\mathcal{C}$ be an ∞ -category which admits pairwise products and let $X \in \mathcal{C}$. Then a sieve $\mathcal{C}_{/X}^0 \subseteq \mathcal{C}_{/X}$ is dense (in the sense of Definition 10.3.1.26) if and only if it is dense when regarded as a subcategory of $\mathcal{C}_{/X}$ (in the sense of Definition 8.4.1.5).*

Proof. Assume that $\mathcal{C}_{/X}^0$ is a dense subcategory of $\mathcal{C}_{/X}$; we will show that it is dense when regarded as a sieve (for the reverse implication, see Warning 10.3.1.27). By assumption, the identity functor $\text{id} : \mathcal{C}_{/X} \rightarrow \mathcal{C}_{/X}$ is left Kan extended from $\mathcal{C}_{/X}^0$. We wish to show that the forgetful functor $U : \mathcal{C}_{/X} \rightarrow \mathcal{C}$ is also left Kan extended from $\mathcal{C}_{/X}^0$. To prove this, it suffices to show that the functor U preserves colimits. This is a special case of Corollary 7.1.4.23, since the functor U admits a right adjoint (given on objects by the construction $Y \mapsto X \times Y$; see Proposition 7.6.1.14). $\square$

04US **Example 10.3.1.30.** Let $\mathcal{C}$ be an ∞ -category. For every object $X \in \mathcal{C}$, the ∞ -category $\mathcal{C}_{/X}$ is a dense sieve on X (see Example 7.3.3.8).

04UT **Remark 10.3.1.31.** Let $\mathcal{C}$ be an ∞ -category and let $\mathcal{C}_{/X}^0 \subseteq \mathcal{C}_{/X}^1 \subseteq \mathcal{C}_{/X}$ be sieves on an object X . If $\mathcal{C}_{/X}^0$ is dense, then $\mathcal{C}_{/X}^1$ is also dense. See Proposition 7.3.8.11.

04UU **Remark 10.3.1.32.** Let $\mathcal{C}$ be an ∞ -category, let Y be an object of $\mathcal{C}$, and let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ be a sieve on Y . Let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$, which we regard as an object of $\mathcal{C}_{/Y}$, and let $\mathcal{C}_{/X}^0 = f^*(\mathcal{C}_{/Y}^0)$ be the pullback sieve (Notation 10.3.1.24). Then the forgetful functor $\mathcal{C}_{/Y} \rightarrow \mathcal{C}$ is left Kan extended from $\mathcal{C}_{/Y}^0$ at f if and only if the following condition is satisfied:

($\ast_f$) The composite map

$$(\mathcal{C}_{/X}^0)^\triangleright \hookrightarrow \mathcal{C}_{/X}^\triangleright \rightarrow \mathcal{C}$$

is a colimit diagram in the ∞ -category $\mathcal{C}$.

In particular, the sieve $\mathcal{C}_{/Y}^0$ is dense if and only if it satisfies condition ($\ast_f$) for *every* morphism $f : X \rightarrow Y$ of $\mathcal{C}$.

Proposition 10.3.1.33. *Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. 04UV For every dense sieve $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$, the pullback sieve $f^\ast \mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/X}$ is also dense.*

Proof. This is an immediate consequence of the criterion of Remark 10.3.1.32. $\square$

Proposition 10.3.1.34 (Transitivity). *Let $\mathcal{C}$ be an ∞ -category, let Y be an object of $\mathcal{C}$, 04UW and let $\mathcal{C}_{/Y}^0, \mathcal{C}_{/Y}^1 \subseteq \mathcal{C}_{/Y}$ be sieves on Y . Assume that:*

- (1) *The sieve $\mathcal{C}_{/Y}^0$ is dense.*
- (2) *For each morphism $f : X \rightarrow Y$ which belongs to $\mathcal{C}_{/Y}^0$, the pullback sieve $f^\ast(\mathcal{C}_{/Y}^1) \subseteq \mathcal{C}_{/X}$ is dense.*

Then $\mathcal{C}_{/Y}^1$ is also a dense sieve.

Proof. Let $U : \mathcal{C}_{/Y} \rightarrow \mathcal{C}$ denote the projection map; we wish to show that U is left Kan extended from $\mathcal{C}_{/Y}^1$. Assumption (1) guarantees that U is left Kan extended from $\mathcal{C}_{/Y}^0$. By virtue of Corollary 7.3.8.13, it will suffice to show that $U|_{\mathcal{C}_{/Y}^0}$ is left Kan extended from the intersection $\mathcal{C}_{/Y}^{01} = \mathcal{C}_{/Y}^0 \cap \mathcal{C}_{/Y}^1$. Fix a morphism $f : X \rightarrow Y$ which belongs to the sieve $\mathcal{C}_{/Y}^0$; we wish to show that U is left Kan extended from $\mathcal{C}_{/Y}^{01}$ at f . This follows from our assumption that $f^\ast \mathcal{C}_{/Y}^{01} = f^\ast \mathcal{C}_{/Y}^1$ is a dense sieve on X . $\square$

10.3.2 Quotient Morphisms

Let X and Y be sets, and let $f : X \rightarrow Y$ be a function. The function f determines an 04WG equivalence relation $\equiv_f$ on X , defined by the requirement

$$(x \equiv_f x') \Leftrightarrow (f(x) = f(x')).$$

If f is surjective, then it induces a bijection from $X/\equiv_f$ to Y . Stated in more categorical terms, this means that for every set S , composition with f induces a bijection

$$\begin{array}{c} \{\text{Functions } Y \rightarrow S\} \\ \downarrow \\ \{\text{Functions } g : X \rightarrow S \text{ satisfying } g(x) = g(x') \text{ when } f(x) = f(x')\}. \end{array}$$

Our goal in this section is to study an ∞ -categorical counterpart of this condition.

04WH **Definition 10.3.2.1.** Let $\mathcal{C}$ be an ∞ -category, let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$, and let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ be the sieve generated by f (see Example 10.3.1.19). We will say that f is a *quotient morphism* if the composite map

$$(\mathcal{C}_{/Y}^0)^\triangleright \hookrightarrow (\mathcal{C}_{/Y})^\triangleright \rightarrow \mathcal{C}$$

is a colimit diagram in the ∞ -category $\mathcal{C}$.

04WJ **Notation 10.3.2.2.** Let $\mathcal{C}$ be an ∞ -category and let f be a morphism of $\mathcal{C}$ having source X and target Y . If f is a quotient morphism, we will often visually emphasize this by denoting f with a double-headed arrow (that is, we will write $f : X \rightrightarrows Y$ in place of $f : X \rightarrow Y$). Beware that this notation does *not* indicate that f is an epimorphism (see Warning 10.3.2.10).

04WK **Exercise 10.3.2.3.** Let $\mathcal{C}$ be an ∞ -category. Show that every isomorphism in $\mathcal{C}$ is a quotient morphism (see Example 10.3.4.3 for a stronger statement).

Stated more informally, a morphism $f : X \rightarrow Y$ is a quotient morphism if the object Y can be recovered as the colimit $\varinjlim_{C \rightarrow Y} C$, indexed by the ∞ -category of morphisms $g : C \rightarrow Y$ which factor through f . If the ∞ -category $\mathcal{C}$ admits pullbacks, this condition admits a more concrete formulation.

04WL **Proposition 10.3.2.4.** Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$ which admits a Čech nerve $\check{C}(X/Y)_\bullet : \mathbf{N}_\bullet(\Delta_+^{\text{op}}) \rightarrow \mathcal{C}$ (see Definition 10.2.5.4). Then f is a quotient morphism if and only if $\check{C}_\bullet(X/Y)$ is a colimit diagram in $\mathcal{C}$.

Stated more informally, Proposition 10.3.2.4 asserts that $f : X \rightarrow Y$ is a quotient morphism if and only if it exhibits Y as a geometric realization of the simplicial object depicted in the diagram

$$\cdots \rightrightarrows X \times_Y X \times_Y X \rightrightarrows X \times_Y X \rightrightarrows X.$$

The proof will require some preliminaries.

04WM **Lemma 10.3.2.5.** Let $\mathcal{C}$ be an ∞ -category and let X be an object of $\mathcal{C}$ which admits a Čech nerve $\check{C}(X)_\bullet : \mathbf{N}_\bullet(\Delta^{\text{op}}) \rightarrow \mathcal{C}$ (see Definition 10.2.4.3). Let $\mathcal{C}^0 \subseteq \mathcal{C}$ be the sieve generated by X (Example 10.3.1.19). Then the functor $\check{C}(X)_\bullet : \mathbf{N}_\bullet(\Delta^{\text{op}}) \rightarrow \mathcal{C}^0$ is right cofinal.

Proof. Let C be an object of $\mathcal{C}$ and let $h^C : \mathcal{C} \rightarrow \mathcal{S}$ be a functor corepresented by C . Since h^C preserves finite products (Proposition 7.4.1.18), the composition

$$\mathbf{N}_\bullet(\Delta^{\text{op}}) \xrightarrow{\check{C}(X)_\bullet} \mathcal{C} \xrightarrow{h^C} \mathcal{S}$$

is a simplicial object of $\mathcal{S}$ which can be identified with the Čech nerve of the Kan complex $h^C(\check{C}(X)_0) \simeq \text{Hom}_{\mathcal{C}}(C, X)$ (Remark 10.2.4.7). If C belongs to the sieve $\mathcal{C}^0$, then the morphism space $\text{Hom}_{\mathcal{C}}(C, X)$ is nonempty. Applying Corollary 10.2.6.15, we conclude that the geometric realization $|h^C(\check{C}(X)_\bullet)|$ is contractible. The desired result now follows by allowing the object C to vary and applying the criterion of Proposition 7.4.3.11. $\square$

Variant 10.3.2.6. Let $\mathcal{C}$ be an ∞ -category, let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$ which admits a Čech nerve $\check{C}(X/Y)_\bullet : \mathbf{N}_\bullet(\Delta_+^{\text{op}}) \rightarrow \mathcal{C}$, and let $\mathcal{C}_{/Y}^0$ denote the sieve generated by f . Then $\check{C}(X/Y)_\bullet$ determines a right cofinal functor $\mathbf{N}_\bullet(\Delta^{\text{op}}) \rightarrow \mathcal{C}_{/Y}^0$. 04WN

Proof. Apply Lemma 10.3.2.5 to the slice ∞ -category $\mathcal{C}_{/Y}$. $\square$

Proof of Proposition 10.3.2.4. Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$ which admits a Čech nerve $\check{C}(X/Y)_\bullet : \mathbf{N}_\bullet(\Delta_+^{\text{op}}) \rightarrow \mathcal{C}$. We wish to show that f is a quotient morphism if and only if $\check{C}(X/Y)_\bullet$ is a colimit diagram in $\mathcal{C}$. Let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ denote the sieve generated by X and let Q denote the composite map

$$(\mathcal{C}_{/Y}^0)^\triangleright \hookrightarrow (\mathcal{C}_{/Y})^\triangleright \rightarrow \mathcal{C}.$$

Let us identify $\check{C}(X/Y)_\bullet$ with a functor $F : \mathbf{N}_\bullet(\Delta^{\text{op}}) \rightarrow \mathcal{C}_{/Y}^{\text{op}}$. Unwinding the definitions, we wish to show that Q is a colimit diagram if and only if the composite functor

$$\mathbf{N}_\bullet(\Delta^{\text{op}})^\triangleright \xrightarrow{F^\triangleright} (\mathcal{C}_{/Y}^0)^\triangleright \xrightarrow{Q} \mathcal{C}$$

is a colimit diagram. This is a special case of Corollary 7.2.2.3, since the functor F is right cofinal (Variant 10.3.2.6). $\square$

Corollary 10.3.2.7. Let $\mathcal{C}$ be a category which admits pullbacks and let $f : X \rightarrow Y$ be a morphism in $\mathcal{C}$. The following conditions are equivalent: 04WP

- (1) The morphism f is a quotient morphism in the ∞ -category $\mathbf{N}_\bullet(\mathcal{C})$ (in the sense of Definition 10.3.2.1).
- (2) The morphism f is a regular epimorphism: that is, it exhibits Y as a coequalizer of the projection maps $X \times_Y X \rightrightarrows X$ (Definition 10.3.0.2).

Proof. Combine Proposition 10.3.2.4 with Corollary 10.2.2.12. $\square$

Example 10.3.2.8. Let X and Y be sets. Then a function $f : X \rightarrow Y$ is a quotient morphism (in the category of sets) if and only if it is surjective (see Example 10.3.0.4). 04WQ

Variant 10.3.2.9. Let $\mathcal{C}$ be a category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. If f is a quotient morphism (in the sense of Definition 10.3.2.1), then it is an epimorphism. 04WR

Proof. Suppose that we are given a pair of morphisms $e_0, e_1 : Y \rightarrow Z$ in $\mathcal{C}$ satisfying $e_0 \circ f = e_1 \circ f$; we wish to show that $e_0 = e_1$. By virtue of our assumption that f is a quotient morphism, it will suffice to show that $e_0 \circ h = e_1 \circ h$ for every morphism $h : C \rightarrow Y$ which belongs to the sieve $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ generated by f . In this case, we can write $h = f \circ g$ for some morphism $g : C \rightarrow X$; the desired result then follows from the calculation

$$e_0 \circ h = e_0 \circ (f \circ g) = (e_0 \circ f) \circ g = (e_1 \circ f) \circ g = e_1 \circ (f \circ g) = e_1 \circ h.$$

□

04WS Warning 10.3.2.10. Let $f : X \rightarrow Y$ be a quotient morphism in an ∞ -category $\mathcal{C}$. If $\mathcal{C}$ is not (the nerve of) an ordinary category, then f need not be an epimorphism. For example, let (X, x) be a pointed Kan complex, and let $\iota : \{x\} \rightarrow X$ denote the inclusion map, which we regard as a morphism in the ∞ -category $\mathcal{S}$ of spaces. Then:

- The morphism ι is an epimorphism (in the ∞ -category $\mathcal{S}$) if and only if X is contractible. To see this, we observe that the identity map id_X and the constant map $c : X \rightarrow \{x\} \xrightarrow{\iota} X$ become homotopic after precomposition with ι ; if ι is an epimorphism, it follows that id_X is homotopic to c .
- The morphism ι is a quotient morphism if and only if X is connected (see Proposition 10.3.4.17).

04WT Proposition 10.3.2.11 (Homotopy Invariance). *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be an equivalence of ∞ -categories and let $f : X \rightarrow Y$ be a morphism in $\mathcal{C}$. Then f is a quotient morphism if and only if $F(f)$ is a quotient morphism in the ∞ -category $\mathcal{D}$.*

Proof. Let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ be the sieve generated by f , and let $\mathcal{D}_{/F(Y)}^0 \subseteq \mathcal{D}_{/F(Y)}$ be the sieve generated by $F(f)$. Since F is fully faithful, $\mathcal{C}_{/Y}^0$ is the inverse image of $\mathcal{D}_{/F(Y)}^0$ under the functor $F_{/Y} : \mathcal{C}_{/Y} \rightarrow \mathcal{D}_{/F(Y)}$ induced by F . Corollary 4.6.4.21 guarantees that $F_{/Y}$ is an equivalence of ∞ -categories, and therefore induces an equivalence $F_{/Y}^0 : \mathcal{C}_{/Y}^0 \rightarrow \mathcal{D}_{/F(Y)}^0$ (Corollary 4.5.2.30). In particular, $F_{/Y}^0$ is right cofinal (Corollary 7.2.1.13). Applying Corollary 7.2.2.3, we deduce that $F(f)$ is a quotient morphism if and only if the composite functor

$$(\mathcal{C}_{/Y}^0)^\triangleright \hookrightarrow (\mathcal{C}_{/Y})^\triangleright \rightarrow \mathcal{C} \xrightarrow{F} \mathcal{D}$$

is a colimit diagram in $\mathcal{D}$. By virtue of Proposition 7.1.4.11, this is equivalent to the requirement that f is a quotient morphism in $\mathcal{C}$. □

04WU Corollary 10.3.2.12. *Let $\mathcal{C}$ be an ∞ -category and let f_0 and f_1 be morphisms of $\mathcal{C}$ which are isomorphic (when viewed as objects of the ∞ -category $\text{Fun}(\Delta^1, \mathcal{C})$). Then f_0 is a quotient morphism if and only if f_1 is a quotient morphism.*

Proof. Let $\text{Isom}(\mathcal{C})$ denote the full subcategory of $\text{Fun}(\Delta^1, \mathcal{C})$ spanned by the isomorphisms. By virtue of Corollary 4.4.5.10, the evaluation functors $\text{ev}_0, \text{ev}_1 : \text{Isom}(\mathcal{C}) \rightarrow \mathcal{C}$ are equivalences of ∞ -categories. Our assumption that f_0 is isomorphic to f_1 guarantees that there exists a morphism $\tilde{f}$ of $\text{Isom}(\mathcal{C})$ satisfying $\text{ev}_0(\tilde{f}) = f_0$ and $\text{ev}_1(\tilde{f}) = f_1$. Using Proposition 10.3.2.11, we see that the condition that f_0 is a quotient morphism in $\mathcal{C}$ is equivalent to the condition that $\tilde{f}$ is a quotient morphism in $\text{Isom}(\mathcal{C})$, which is also equivalent to the condition that f_1 is a quotient morphism in $\mathcal{C}$. $\square$

Example 10.3.2.13. Let $\mathcal{C}$ be an ∞ -category containing a pair of morphisms $f_0, f_1 : X \rightarrow Y$ 04WV which are homotopic. Then f_0 is a quotient morphism if and only if f_1 is a quotient morphism. This is a special case of Corollary 10.3.2.12, but can also be deduced immediately from the definition (since f_0 and f_1 generate the same sieve on Y).

Proposition 10.3.2.14. Let $\mathcal{C}$ be an ∞ -category, let $q : K \rightarrow \mathcal{C}$ be a diagram, and let 04WW $\tilde{f} : \tilde{X} \rightarrow \tilde{Y}$ be a morphism in the ∞ -category $\mathcal{C}_{/q}$ having image $f : X \rightarrow Y$ in $\mathcal{C}$. If f is a quotient morphism in $\mathcal{C}$, then $\tilde{f}$ is a quotient morphism in $\mathcal{C}_{/q}$.

Proof. Set $\tilde{\mathcal{C}} = \mathcal{C}_{/q}$, so that we have a commutative diagram of forgetful functors

$$\begin{array}{ccc} \tilde{\mathcal{C}}_{/\tilde{Y}} & \xrightarrow{V'} & \mathcal{C}_{/Y} \\ \downarrow \tilde{U} & & \downarrow U \\ \tilde{\mathcal{C}} & \xrightarrow{V} & \mathcal{C} \end{array}$$

Let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ denote the sieve generated by f , so that $\tilde{\mathcal{C}}_{/\tilde{Y}}^0 = V'^{-1}\mathcal{C}_{/Y}^0$ is the sieve generated by $\tilde{f}$. Note that V is a right fibration (Proposition 4.3.6.1), so that V' is a trivial Kan fibration (Corollary 4.3.7.13). In particular, the induced map $\tilde{\mathcal{C}}_{/\tilde{Y}}^0 \rightarrow \mathcal{C}_{/Y}^0$ is a trivial Kan fibration, and therefore right cofinal (Corollary 7.2.1.13). Combining our assumption that f is a quotient morphism with Corollary 7.2.2.3, we deduce that the composite functor

$$(\tilde{\mathcal{C}}_{/\tilde{Y}}^0)^{\triangleright} \hookrightarrow (\tilde{\mathcal{C}}_{/\tilde{Y}})^{\triangleright} \rightarrow \tilde{\mathcal{C}} \xrightarrow{V} \mathcal{C}$$

is a colimit diagram in the ∞ -category $\mathcal{C}$. Since the functor V is conservative and creates colimits (Proposition 7.1.4.21), we conclude that $\tilde{f}$ is a quotient morphism. $\square$

We close this section by recording two negative results, highlighting that the collection of quotient morphisms in an ∞ -category $\mathcal{C}$ has poor closure properties in general:

- The collection of quotient morphisms need not be closed under composition (Exercise 10.3.2.15).

- The collection of quotient morphisms need not be closed under the formation of pullbacks (Exercise 10.3.2.16).

Both of these defects can be remedied by working instead with the class of *universal quotient morphisms*, which we study in §10.3.4 (see Definition 10.3.4.1).

04WX **Exercise 10.3.2.15.** Let $\mathcal{C}$ be the (nerve of the) ordinary category depicted informally by the diagram

$$\begin{array}{ccccc} \tilde{X} & & \tilde{Y} & & \\ \parallel & \searrow & \parallel & \searrow & \\ e_0 & & g_0 & & g_1 \\ \parallel & & \parallel & & \\ e_1 & & g_1 & & \\ \downarrow & & \downarrow & & \\ X & \xrightarrow{f} & Y & \xrightarrow{h} & Z, \end{array}$$

so that $f \circ e_0 = f \circ e_1$ and $h \circ g_0 = h \circ g_1$. Show that f and h are quotient morphisms in $\mathcal{C}$, but the composition $(h \circ f) : X \rightarrow Z$ is not a quotient morphism.

04WY **Exercise 10.3.2.16.** Let $\mathcal{C}$ be the category of partially ordered sets (where morphisms are nondecreasing functions). Let $Q = \{a, b, c, d\}$ be a set with four elements, endowed with the partial ordering indicated in the diagram

$$a \longrightarrow b \longleftarrow c \longrightarrow d.$$

Let $f : Q \rightarrow [2] = \{0 < 1 < 2\}$ be the nondecreasing function given by

$$f(a) = 0 \quad f(b) = 1 = f(c) \quad f(d) = 2,$$

so that we have a pullback diagram of partially ordered sets

$$\begin{array}{ccc} \{a, d\} & \longrightarrow & Q \\ \downarrow f_0 & & \downarrow f \\ \{0 < 2\} & \longrightarrow & [2]. \end{array} \tag{10.8}$$

Show that f is a quotient morphism in (the nerve of) the category $\mathcal{C}$, but that f_0 is not.

04X0 **Variant 10.3.2.17.** In the situation of Exercise 10.3.2.16, we can apply the nerve functor to (10.8) and obtain a commutative diagram of ∞ -categories

$$\begin{array}{ccc} \{a, d\} & \longrightarrow & N_{\bullet}(Q) \\ \downarrow F_0 & & \downarrow F \\ N_{\bullet}(\{0 < 2\}) & \longrightarrow & \Delta^2, \end{array}$$

which we can regard as a pullback square in the ∞ -category $\mathcal{QC}$. Show that F is a quotient morphism in $\mathcal{QC}$, but that F_0 is not (beware that this is not a formal consequence of Exercise 10.3.2.16: the construction $P \mapsto N_\bullet(P)$ does not preserve quotient morphisms in general).

10.3.3 Images

Let X and Y be sets. Recall that the *image* of a function $f : X \rightarrow Y$ is defined to be the subset $\text{im}(f) = \{y \in Y : f^{-1}\{y\} \neq \emptyset\}$. More abstractly, the set $\text{im}(f)$ is characterized (up to isomorphism) by the requirement that f factors as a composition

$$X \xrightarrow{q} \text{im}(f) \xrightarrow{i} Y,$$

where q is surjective and i is injective. This motivates the following:

Definition 10.3.3.1. Let $\mathcal{C}$ be an ∞ -category, let Y be an object of $\mathcal{C}$, and let $Y_0 \subseteq Y$ be a subobject: that is, an object of $\mathcal{C}$ equipped with a (specified) monomorphism $i : Y_0 \hookrightarrow Y$ (see Definition 9.6.4.26). We will say that Y_0 is an *image* of a morphism $f : X \rightarrow Y$ if the homotopy class $[f]$ factors as a composition $[i] \circ [q]$, where $q : X \rightarrow Y_0$ is a quotient morphism in $\mathcal{C}$.

Remark 10.3.3.2. In the situation of Definition 10.3.3.1, our assumption that i is a monomorphism guarantees that the composition map $\text{Hom}_{\text{hc}}(X, Y_0) \xrightarrow{[i] \circ} \text{Hom}_{\text{hc}}(X, Y)$ is injective. It follows that if there exists a morphism $q : X \rightarrow Y_0$ satisfying $[f] = [i] \circ [q]$, then q is uniquely determined up to homotopy. In particular, the condition that q is a quotient morphism is independent of the choice of q (see Example 10.3.2.13).

Remark 10.3.3.3. In the situation of Definition 10.3.3.1, Y_0 is an image of f if and only if there exists a 2-simplex

$$\begin{array}{ccc} & Y_0 & \\ q \nearrow & & \searrow i \\ X & \xrightarrow{f} & Y \end{array} \quad (10.9)$$

in the ∞ -category $\mathcal{C}$, where q is a quotient morphism. If this condition is satisfied, we say that the 2-simplex (10.9) *exhibits* Y_0 as an *image* of f .

Example 10.3.3.4 (Images of Sets). Let $f : X \rightarrow Y$ be a function between sets, and set $Y_0 = \{y \in Y : f^{-1}\{y\} \neq \emptyset\}$. Then f determines a surjection from X to Y_0 , which is a quotient morphism in the category of sets (Example 10.3.2.8). It follows that the

commutative diagram

$$\begin{array}{ccc} & Y_0 & \\ f \nearrow & & \searrow i \\ X & \xrightarrow{f} & Y \end{array}$$

exhibits Y_0 as an image of f .

04X7 **Example 10.3.3.5** (Images of Monomorphisms). Let $\mathcal{C}$ be an ∞ -category and let $f : X \hookrightarrow Y$ be a monomorphism in $\mathcal{C}$. Since the identity map id_X is a quotient morphism (Exercise 10.3.2.3), the left-degenerate 2-simplex

$$\begin{array}{ccc} & X & \\ \text{id}_X \nearrow & & \searrow f \\ X & \xrightarrow{f} & Y \end{array}$$

exhibits X as an image of f .

04X8 **Proposition 10.3.3.6** (Images of Quotient Morphisms). *Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. Then f is a quotient morphism if and only if Y is an image of f (when regarded as a subobject of itself).*

Proof. Assume first that f is a quotient morphism. Since the identity map id_Y is a monomorphism (Example 9.6.4.9), the right-degenerate 2-simplex

$$\begin{array}{ccc} & Y & \\ f \nearrow & & \searrow \text{id}_Y \\ X & \xrightarrow{f} & Y \end{array}$$

exhibits Y as an image of f . Conversely, if Y is an image of f , then f factors as the composition of a quotient morphism and an isomorphism, and is therefore a quotient morphism by virtue of Corollary 10.3.2.12. $\square$

04X9 **Warning 10.3.3.7.** The terminology of Definition 10.3.3.1 is not entirely standard. In the setting of additive categories, many authors refer to an object Y as the *image* of a morphism $f : X \rightarrow Y$ if it is a kernel of the tautological map $Y \rightarrow \text{coker}(f)$. This agrees with Definition 10.3.3.1 when $\mathcal{C}$ is an abelian category (Proposition [?]), but not in general.

Warning 10.3.3.8 (Essential Images). Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories. Recall 04XA that the *essential image* of F is the full subcategory $\mathcal{D}_0 \subseteq \mathcal{D}$ spanned by objects $D \in \mathcal{D}$ which are isomorphic to $F(C)$, for some object $C \in \mathcal{C}$ (Definition 4.6.2.12). In this case, the inclusion map $\iota : \mathcal{D}_0 \hookrightarrow \mathcal{D}$ is always a monomorphism in $\mathcal{QC}$ (Corollary 9.6.4.34), and F factors (uniquely) as the composition of ι with a functor $F_0 : \mathcal{C} \rightarrow \mathcal{D}_0$. Beware that this factorization generally does *not* exhibit $\mathcal{D}_0$ as an image of F in the ∞ -category $\mathcal{QC}$, in the sense of Definition 10.3.3.1: that is, the functor F_0 need not be a quotient morphism in $\mathcal{QC}$. This fails, for example, if F is the inclusion functor $\partial\Delta^1 \hookrightarrow \Delta^1$.

We now show that if $f : X \rightarrow Y$ is a morphism in $\mathcal{C}$ which admits an image Y_0 , then the subobject $Y_0 \subseteq Y$ is uniquely determined up to isomorphism.

Lemma 10.3.3.9. *Let $q : X \twoheadrightarrow Y$ be a quotient morphism in an ∞ -category $\mathcal{C}$. Then every 04XB subterminal object $C \in \mathcal{C}$ is q -local.*

Proof. We wish to show that the composition map $\mathrm{Hom}_{\mathcal{C}}(Y, C) \xrightarrow{\circ[q]} \mathrm{Hom}_{\mathcal{C}}(X, C)$ is a homotopy equivalence of Kan complexes. Since C is subterminal, both mapping spaces are either empty or contractible. It will therefore suffice to show that if $\mathrm{Hom}_{\mathcal{C}}(X, C)$ is nonempty, then $\mathrm{Hom}_{\mathcal{C}}(Y, C)$ is also nonempty.

Let $\mathcal{C}_{/Y}^0$ be the sieve generated by q . Since q is a quotient morphism, Y is a colimit of the diagram

$$F : \mathcal{C}_{/Y}^0 \hookrightarrow \mathcal{C}_{/Y} \rightarrow \mathcal{C};$$

that is, it can be lifted to an initial object $\tilde{Y}$ of the coslice ∞ -category $\mathcal{C}_{F/}$. Since $C \in \mathcal{C}$ is subterminal, the projection map $U : \mathcal{C}_{/C} \rightarrow \mathcal{C}$ restricts to a trivial Kan fibration from $\mathcal{C}_{/C}$ to a sieve $\mathcal{C}^1 \subseteq \mathcal{C}$. The assumption that $\mathrm{Hom}_{\mathcal{C}}(X, C)$ is nonempty guarantees that F takes values in $\mathcal{C}^1$ and therefore factors through $\mathcal{C}_{/C}$. A choice of factorization determines a lift of C to an object $\tilde{C} \in \mathcal{C}_{F/}$. Since $\tilde{Y}$ is an initial object of $\mathcal{C}_{F/}$, we can choose a morphism $\tilde{u} : \tilde{Y} \rightarrow \tilde{C}$ in the ∞ -category $\mathcal{C}_{F/}$. Applying the forgetful functor $\mathcal{C}_{F/} \rightarrow \mathcal{C}$, we obtain a morphism $u : Y \rightarrow C$ in $\mathcal{C}$. $\square$

Lemma 10.3.3.10. *Let $\mathcal{C}$ be an ∞ -category and let $q : X \twoheadrightarrow Y$ be a quotient morphism in 04XC $\mathcal{C}$. Then q is left orthogonal to every monomorphism $i : C \hookrightarrow D$ of $\mathcal{C}$.*

Proof. Let $U : \mathcal{C}_{/D} \rightarrow \mathcal{C}$ denote the projection map, so that the monomorphism i can be identified with a subterminal object $\tilde{C} \in \mathcal{C}_{/D}$ satisfying $U(\tilde{C}) = C$ (Remark 9.6.4.16). By virtue of Corollary 9.5.6.14, it will suffice to show that the object $\tilde{C}$ is $\tilde{q}$ -local for every morphism $\tilde{q}$ of $\mathcal{C}_{/D}$ satisfying $U(\tilde{q}) = q$. This follows from Lemma 10.3.3.9, since $\tilde{q}$ is a quotient morphism in the ∞ -category $\mathcal{C}_{/D}$ (Proposition 10.3.2.14). $\square$

04XD **Proposition 10.3.3.11.** *Let $\mathcal{C}$ be an ∞ -category containing a 2-simplex*

04XE

$$\begin{array}{ccc} X & & \\ \downarrow q & \searrow f & \\ Y_0 & \xrightarrow{i_0} & Y \end{array} \quad (10.10)$$

which exhibits Y_0 as an image of f . Then, for any monomorphism $i_1 : Y_1 \hookrightarrow Y$ of $\mathcal{C}$, the following conditions are equivalent:

- (1) *The morphism f factors (up to homotopy) through i_1 . That is, there exists a 2-simplex*

04XF

$$\begin{array}{ccc} X & \xrightarrow{g} & Y_1 \\ & \searrow f & \downarrow i_1 \\ & & Y \end{array} \quad (10.11)$$

in the ∞ -category $\mathcal{C}$.

- (2) *The containment $[Y_0] \subseteq [Y_1]$ holds (where we regard the isomorphism classes $[Y_0]$ and $[Y_1]$ as elements of the partially ordered set $\text{Sub}(Y)$; see Notation 9.6.4.27).*

Proof. The implication (2) $\Rightarrow$ (1) follows immediately from the definitions. To prove the converse, we note that in the situation of (1), we can amalgamate the diagrams (10.10) and (10.11) to obtain a lifting problem

$$\begin{array}{ccc} X & \xrightarrow{g} & Y_1 \\ \downarrow q & \nearrow \text{---} & \downarrow i_1 \\ Y_0 & \xrightarrow{i_0} & Y \end{array}$$

in the ∞ -category $\mathcal{C}$. Since q is a quotient morphism and i_1 is a monomorphism, Lemma 10.3.3.10 guarantees that this lifting problem admits an (essentially unique) solution, which proves (2). $\square$

04XG **Notation 10.3.3.12.** Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism in $\mathcal{C}$ which admits an image $Y_0 \subseteq Y$. It follows from Proposition 10.3.3.11 that the isomorphism class $[Y_0]$ is uniquely determined by f (as an object of the partially ordered set $\text{Sub}(Y)$; see

Notation 9.6.4.27). To emphasize this, we will denote the isomorphism class $[Y_0]$ by $\text{im}(f)$ and refer to it as *the image of f* . We will sometimes abuse notation by identifying $\text{im}(f)$ with the object Y_0 , viewed either as an object of the slice ∞ -category $\mathcal{C}/_Y$ or as an object of the ∞ -category $\mathcal{C}$.

Corollary 10.3.3.13. *Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. Then f is an isomorphism if and only if it is both a monomorphism and a quotient morphism.* 05HS

Proof. Without loss of generality, we may assume that f is a monomorphism. Applying Example 10.3.3.5, we see that the isomorphism class $[X] \in \text{Sub}(Y)$ is an image of f . It follows that f is an isomorphism if and only if $\text{im}(f) = [Y]$. By virtue of Proposition 10.3.3.6, this is equivalent to the requirement that f is a quotient morphism. $\square$

Proposition 10.3.3.14 (Uniqueness of Images). *Let $\mathcal{C}$ be an ∞ -category and let $\text{Fun}'(\Delta^2, \mathcal{C})$ denote the full subcategory of $\text{Fun}(\Delta^2, \mathcal{C})$ spanned by those 2-simplices* 04XH

$$\begin{array}{ccc} & Y_0 & \\ q \nearrow & & \searrow i \\ X & \xrightarrow{f} & Y \end{array}$$

which exhibit Y_0 as an image of f (see Remark 10.3.3.3). Then the restriction functor

$$D : \text{Fun}'(\Delta^2, \mathcal{C}) \rightarrow \text{Fun}(\Delta^1, \mathcal{C}) \quad \sigma \mapsto d_1^2(\sigma)$$

is a trivial Kan fibration from $\text{Fun}'(\Delta^2, \mathcal{C})$ to the full subcategory $\text{Fun}'(\Delta^1, \mathcal{C}) \subseteq \text{Fun}(\Delta^1, \mathcal{C})$ spanned by those morphisms $f : X \rightarrow Y$ which admit an image in $\mathcal{C}$.

Proof. Combining Lemma 10.3.3.10 with Theorem 9.5.7.2, we deduce that the functor D is fully faithful, and therefore induces an equivalence from $\text{Fun}'(\Delta^2, \mathcal{C})$ to the full subcategory $\text{Fun}'(\Delta^1, \mathcal{C}) \subseteq \text{Fun}(\Delta^1, \mathcal{C})$. To complete the proof, it will suffice to show that D is an isofibration (Proposition 4.5.5.20). This follows from Corollary 4.4.5.3, since $\text{Fun}'(\Delta^2, \mathcal{C})$ is a replete subcategory of $\text{Fun}(\Delta^2, \mathcal{C})$ (see Corollary 10.3.2.12 and Remark 9.6.4.25). $\square$

Remark 10.3.3.15. Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. Suppose that $\mathcal{C}$ admits pullbacks, so that f admits a Čech nerve $\check{C}_\bullet(X/Y)$ (Proposition 10.2.5.6). If f has an image, then $\text{im}(f)$ can be identified with the geometric realization of the underlying simplicial object of $\check{C}_\bullet(X/Y)$. To see this, choose a 2-simplex 04XJ

$$\begin{array}{ccc} & Y_0 & \\ q \nearrow & & \searrow i \\ X & \xrightarrow{f} & Y \end{array}$$

which exhibits Y_0 as an image of f . Since i is a monomorphism, Remark 10.3.1.17 supplies an isomorphism between the underlying simplicial objects of $\check{C}_\bullet(X/Y)$ and $\check{C}_\bullet(X/Y_0)$. It will therefore suffice to show that $\check{C}_\bullet(X/Y_0)$ is a colimit diagram in $\mathcal{C}$, which is a reformulation of our assumption that q is a quotient morphism (Proposition 10.3.2.4).

04XK Warning 10.3.3.16. Let $\mathcal{C}$ be an ∞ -category which admits pullbacks, let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$, and let $C_\bullet$ denote the underlying simplicial object of the Čech nerve $\check{C}_\bullet(X/Y)$. Remark 10.3.3.15 asserts that if f has an image, then that image can be identified with a geometric realization of $C_\bullet$. Beware that the converse is false in general. Suppose that $C_\bullet$ admits a geometric realization $|C_\bullet|$, given by the image on an initial object E of the coslice ∞ -category $\mathcal{C}_{C_\bullet/}$. The augmented simplicial object $\check{C}_\bullet(X/Y)$ determines another object $\tilde{Y} \in \mathcal{C}_{C_\bullet/}$, so there is an (essentially unique) morphism from E to $\tilde{Y}$. The forgetful functor $\mathcal{C}_{C_\bullet/} \rightarrow \mathcal{C}_{X/}$ carries this morphism to a 2-simplex

04XL

$$\begin{array}{ccc} & |C_\bullet| & \\ q \nearrow & & \searrow i \\ X & \xrightarrow{f} & Y \end{array} \quad (10.12)$$

in the ∞ -category $\mathcal{C}$. In this situation, the following conditions are equivalent:

- The morphism i is a monomorphism.
- The diagram (10.12) exhibits $|C_\bullet|$ as an image of f .
- The morphism f has an image in $\mathcal{C}$.

04XM Definition 10.3.3.17. Let $\mathcal{C}$ be an ∞ -category. We say that $\mathcal{C}$ *has images* if every morphism $f : X \rightarrow Y$ of $\mathcal{C}$ has an image $\mathrm{im}(f) \in \mathrm{Sub}(Y)$.

04XN Remark 10.3.3.18 (Functoriality of Images). Let $\mathcal{C}$ be an ∞ -category and let $\mathrm{Fun}'(\Delta^2, \mathcal{C}) \subseteq \mathrm{Fun}(\Delta^2, \mathcal{C})$ be the full subcategory described in Proposition 10.3.3.14. Then $\mathcal{C}$ has images if and only if the restriction functor

$$D : \mathrm{Fun}'(\Delta^2, \mathcal{C}) \rightarrow \mathrm{Fun}(\Delta^1, \mathcal{C}) \quad \sigma \mapsto d_1^2(\sigma)$$

is a trivial Kan fibration. If this condition is satisfied, then D admits a section which carries each morphism $f : X \rightarrow Y$ of $\mathcal{C}$ to a 2-simplex

$$\begin{array}{ccc} & \mathrm{im}(f) & \\ \nearrow & & \searrow \\ X & \xrightarrow{f} & Y \end{array}$$

which exhibits $\mathrm{im}(f)$ as an image of f . In particular, we can promote the construction $f \mapsto \mathrm{im}(f)$ as a functor of ∞ -categories $\mathrm{Fun}(\Delta^1, \mathcal{C}) \rightarrow \mathcal{C}$.

Remark 10.3.3.19. Let $\mathcal{C}$ be an ∞ -category, let Q denote the collection of all quotient morphisms in $\mathcal{C}$, and let M denote the collection of all monomorphisms in $\mathcal{C}$. Then Q and M are closed under isomorphism (see Corollary 10.3.2.12 and Remark 9.6.4.25), and Q is left orthogonal to M (Lemma 10.3.3.10). It follows that $\mathcal{C}$ has images if and only if the pair (Q, M) is a factorization system on $\mathcal{C}$ (Definition 9.5.8.1). 04XP

Proposition 10.3.3.20. Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. If $\mathcal{C}$ has images, the following conditions are equivalent: 04XQ

- (1) The morphism f is a quotient morphism.
- (2) The morphism f is left orthogonal to every monomorphism in $\mathcal{C}$.
- (3) The morphism f is weakly left orthogonal to every monomorphism in $\mathcal{C}$.

Proof. Combine Remark 10.3.3.19 with Proposition 9.5.8.11. □

Corollary 10.3.3.21. Let $\mathcal{C}$ be an ∞ -category which has images, and let 04XR

$$\begin{array}{ccc} & Y & \\ f \nearrow & & \searrow g \\ X & \xrightarrow{h} & Z \end{array}$$

be a 2-simplex of $\mathcal{C}$, where f is a quotient morphism. Then g is a quotient morphism if and only if h is a quotient morphism. In particular, the collection of quotient morphisms is closed under composition.

Proof. Combine Proposition 10.3.3.20 with Corollary 9.5.6.16. □

Corollary 10.3.3.22. Let $\mathcal{C}$ be an ∞ -category containing a pushout diagram 04XS

$$\begin{array}{ccc} X & \xrightarrow{\quad} & X' \\ \downarrow f & & \downarrow f' \\ Y & \xrightarrow{\quad} & Y' \end{array}$$

If $\mathcal{C}$ has images and f is a quotient morphism, then f' is also a quotient morphism.

Proof. Combine Proposition 10.3.3.20 with Corollary 9.5.6.19. $\square$

04XT **Corollary 10.3.3.23.** *Let $\mathcal{C}$ be an ∞ -category with images. Then the collection of quotient morphisms in $\mathcal{C}$ is closed under retracts (in the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$).*

Proof. Combine Proposition 10.3.3.20 with Corollary 9.5.6.18. $\square$

04XU **Exercise 10.3.3.24.** Show that the conclusion of Corollary 10.3.3.23 holds for every ∞ -category $\mathcal{C}$: that is, it is not necessary to assume that $\mathcal{C}$ has images.

10.3.4 Universal Quotient Morphisms

04XV Let $\mathcal{C}$ be an ∞ -category. In §10.3.2, we observed that the collection of quotient morphisms in $\mathcal{C}$ can exhibit some bad behavior: they need not be closed under composition (Exercise 10.3.2.15) or under the formation of pullbacks (Exercise 10.3.2.16). These deficiencies can be remedied by adopting a more restrictive definition.

04XW **Definition 10.3.4.1** (Universal Quotient Morphisms). Let $\mathcal{C}$ be an ∞ -category, let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$, and let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ be the sieve generated by f (see Example 10.3.1.19). We say that f is a *universal quotient morphism* if the sieve $\mathcal{C}_{/X}^0$ is dense (in the sense of Definition 10.3.1.26).

04XX **Remark 10.3.4.2.** Let $\mathcal{C}$ be an ∞ -category and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$, and let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ be the sieve generated by f . Then f is a quotient morphism if and only if the forgetful functor $\mathcal{C}_{/Y} \rightarrow \mathcal{C}$ is left Kan extended from $\mathcal{C}_{/Y}^0$ at the object $\mathrm{id}_Y : Y \rightarrow Y$ (see Remark 10.3.1.32). In particular, if f is a universal quotient morphism, then f is a quotient morphism. Beware that the converse is false in general (see Example 10.3.4.11).

04XY **Example 10.3.4.3.** Let $\mathcal{C}$ be an ∞ -category, let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$, and let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ be the sieve generated by f . If f admits a right homotopy inverse $s : Y \rightarrow X$, then the sieve $\mathcal{C}_{/Y}^0$ coincides with $\mathcal{C}_{/Y}$, and is therefore dense. It follows that f is a universal quotient morphism. In particular, every isomorphism is a universal quotient morphism.

04XZ **Remark 10.3.4.4.** Let $\mathcal{C}$ be an ∞ -category, let Y be an object of $\mathcal{C}$, and let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ be a sieve on Y . If $\mathcal{C}_{/Y}^0$ contains a universal quotient morphism $f : X \rightarrow Y$, then it is dense. See Remark 10.3.1.31.

04Y0 **Remark 10.3.4.5.** Let $\mathcal{C}$ be an ∞ -category containing a 2-simplex

$$\begin{array}{ccc} & Y & \\ f \nearrow & & \searrow g \\ X & \xrightarrow{h} & Z. \end{array}$$

If h is a universal quotient morphism, then g is also a universal quotient morphism. This is a special case of Remark 10.3.4.4.

Proposition 10.3.4.6. *Let $\mathcal{C}$ be an ∞ -category containing a pullback diagram*

04Y1

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow f' & & \downarrow f \\ Y' & \xrightarrow{u} & Y. \end{array}$$

04Y2

(10.13)

If f is a universal quotient morphism, then f' is also a universal quotient morphism.

Proof. Let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ be the sieve generated by f . Our assumption that f is a universal quotient morphism guarantees that $\mathcal{C}_{/Y}^0$ is a dense sieve on Y . Applying Proposition 10.3.1.33, we deduce that the pullback $u^* \mathcal{C}_{/Y}^0$ is a dense sieve on Y' . Since (10.13) is a pullback square, the sieve $u^* \mathcal{C}_{/Y}^0$ is generated by f' , so that f' is also a universal quotient morphism. $\square$

The terminology of Definition 10.3.4.1 is motivated by the following result:

Corollary 10.3.4.7. *Let $\mathcal{C}$ be an ∞ -category which admits pullbacks and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. The following conditions are equivalent:*

04Y3

(1) *The morphism f is a universal quotient morphism.*

(2) *For every pullback diagram*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow f' & & \downarrow f \\ Y' & \longrightarrow & Y \end{array}$$

of $\mathcal{C}$, the morphism f' is a universal quotient morphism.

(3) *For every pullback diagram*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow f' & & \downarrow f \\ Y' & \longrightarrow & Y \end{array}$$

of $\mathcal{C}$, the morphism f' is a quotient morphism.

Proof. The implication (1) $\Rightarrow$ (2) follows from Proposition 10.3.4.6, the implication (2) $\Rightarrow$ (3) from Remark 10.3.4.2, and the implication (3) $\Rightarrow$ (1) from the criterion of Remark 10.3.1.32 (together with Example 10.3.1.25). $\square$

04Y4 **Corollary 10.3.4.8.** *Let $\mathcal{C}$ be an ∞ -category which admits pullbacks. The following conditions are equivalent:*

- (1) *Every quotient morphism in $\mathcal{C}$ is a universal quotient morphism.*
- (2) *The collection of quotient morphisms in $\mathcal{C}$ is closed under pullbacks. That is, for every pullback diagram*

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow f' & & \downarrow f \\ Y' & \longrightarrow & Y \end{array}$$

where f is a quotient morphism, f' is also a quotient morphism.

04Y5 **Corollary 10.3.4.9.** *Let X and Y be sets, and let $f : X \rightarrow Y$ be a function. The following conditions are equivalent:*

- (1) *The function f is a universal quotient morphism in the category of sets.*
- (2) *The function f is a quotient morphism in the category of sets.*
- (3) *The function f is surjective.*

Proof. The implication (1) $\Rightarrow$ (2) follows from Remark 10.3.4.2 and the equivalence (2) $\Leftrightarrow$ (3) follows from Example 10.3.2.8. Since the collection of surjections is closed under pullbacks, Corollary 10.3.4.7 guarantees that (3) $\Rightarrow$ (1). $\square$

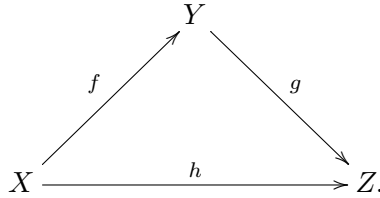

04Y6 **Corollary 10.3.4.10.** *Let $\mathcal{C}$ be an ∞ -category which admits pullbacks and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. Then f is a universal quotient morphism if and only if $\check{C}(X/Y)_\bullet$ is a universal colimit diagram in $\mathcal{C}$ (see Definition 7.7.1.15). In particular, if geometric realizations in $\mathcal{C}$ are universal, then every quotient morphism in $\mathcal{C}$ is a universal quotient morphism.*

Proof. Combine Corollary 10.3.4.7 and Proposition 10.3.2.4 (together with Remark 10.2.5.7). $\square$

04Y7 **Example 10.3.4.11.** Let $\mathcal{C}$ be (the nerve of) the category of partially ordered sets. Then Exercise 10.3.2.16 supplies an example of a quotient morphism $f : Q \twoheadrightarrow [2]$ in $\mathcal{C}$ which is not a universal quotient morphism.

Proposition 10.3.4.12. *Let $\mathcal{C}$ be an ∞ -category containing a 2-simplex*

04Y8

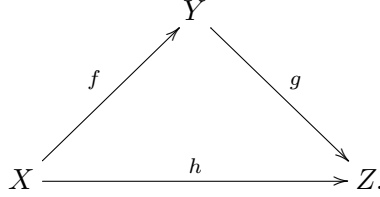

If f and g are universal quotient morphisms, then h is also a universal quotient morphism.

Proof. Let $\mathcal{C}_{/Z}^0$ and $\mathcal{C}_{/Z}^1$ be the sieves generated by g and h , respectively. By assumption, the sieve $\mathcal{C}_{/Z}^0$ is dense, and we wish to show that $\mathcal{C}_{/Z}^1$ is also dense. By virtue of Proposition 10.3.1.34, it will suffice to show that for every morphism $u : Z' \rightarrow Z$ which belongs to $\mathcal{C}_{/Z}^0$, the pullback $u^*\mathcal{C}_{/Z'}^1$ is a dense sieve on Z' . Using Proposition 10.3.1.33, we can reduce to the special case where u is the morphism $g : Y \rightarrow Z$. In this case, the pullback sieve $u^*(\mathcal{C}_{/Y}^1) \subseteq \mathcal{C}_{/Y}$ contains the universal quotient morphism $f : X \rightarrow Y$, and is therefore dense (Remark 10.3.4.4). $\square$

Variant 10.3.4.13. *Let $\mathcal{C}$ be an ∞ -category containing a 2-simplex*

04Y9

If f is a universal quotient morphism and g is a quotient morphism, then h is a quotient morphism.

Proof. Let $\mathcal{C}_{/Z}^0$ and $\mathcal{C}_{/Z}^1$ be the sieves on X generated by g and h , respectively. Our assumption that g is a quotient morphism guarantees that the functor

$$\overline{Q} : (\mathcal{C}_{/Z}^0)^\triangleright \rightarrow (\mathcal{C}_{/Z})^\triangleright \rightarrow \mathcal{C}$$

is a colimit diagram in the ∞ -category $\mathcal{C}$, and we wish to show that the restriction $\overline{Q}|_{(\mathcal{C}_{/Z}^1)^\triangleright}$ is also a colimit diagram. By virtue of Corollary 7.3.8.3, it will suffice to show that the restriction $Q = \overline{Q}|_{\mathcal{C}_{/Z}^0}$ is left Kan extended from the full subcategory $\mathcal{C}_{/Z}^1$. Fix a morphism $u : Z' \rightarrow Z$ which belongs to the sieve $\mathcal{C}_{/Z}^0$; we wish to show that Q is left Kan extended from $\mathcal{C}_{/Z}^1$ at u . In fact, we will prove a slightly stronger assertion: the pullback $u^*(\mathcal{C}_{/Z}^1)$ is a dense sieve on Z' . Using Proposition 10.3.1.33, we are reduced to proving this in the special case where u is the morphism $g : Y \rightarrow Z$. In this case, the sieve $u^*(\mathcal{C}_{/Z}^1)$ contains the quotient morphism f , and is therefore dense by virtue of Remark 10.3.4.4. $\square$

04YA **Corollary 10.3.4.14.** *Let $\mathcal{C}$ be an ∞ -category. Then the collection of universal quotient morphisms of $\mathcal{C}$ is closed under retracts (in the ∞ -category $\mathrm{Fun}(\Delta^1, \mathcal{C})$).*

Proof. Let $f : X \twoheadrightarrow Y$ be a universal quotient morphism in $\mathcal{C}$ and let $f' : X' \rightarrow Y'$ be a retract of f , so that we have a commutative diagram

$$\begin{array}{ccccc} X' & \longrightarrow & X & \xrightarrow{r_X} & X' \\ \downarrow f' & & \downarrow f & & \downarrow f' \\ Y' & \longrightarrow & Y & \xrightarrow{r_Y} & Y' \end{array}$$

where the vertical compositions are homotopic to the identity. We wish to show that f' is also a universal quotient morphism. By virtue of Remark 10.3.4.5, it will suffice to show that the composition $(f' \circ r_X) : X \rightarrow Y'$ is a universal quotient morphism. Using the commutativity of the diagram, we can write $f' \circ r_X$ as a composition of r_Y with f . Since f is a universal quotient morphism by assumption and r_Y is a universal quotient morphism by virtue of Example 10.3.4.3, the desired result follows from Proposition 10.3.4.12. $\square$

04YB **Proposition 10.3.4.15.** *Let $\mathcal{C}$ be an ∞ -category, let $q : K \rightarrow \mathcal{C}$ be a diagram, and let $\tilde{f} : \tilde{X} \rightarrow \tilde{Y}$ be a morphism in the ∞ -category $\mathcal{C}_{/q}$ having image $f : X \rightarrow Y$ in $\mathcal{C}$. If f is a universal quotient morphism in $\mathcal{C}$, then $\tilde{f}$ is a universal quotient morphism in $\mathcal{C}_{/q}$.*

Proof. Set $\tilde{\mathcal{C}} = \mathcal{C}_{/q}$, so that we have a commutative diagram of forgetful functors

$$\begin{array}{ccc} \tilde{\mathcal{C}}_{/\tilde{Y}} & \xrightarrow{V'} & \mathcal{C}_{/Y} \\ \downarrow \tilde{U} & & \downarrow U \\ \tilde{\mathcal{C}} & \xrightarrow{V} & \mathcal{C}. \end{array}$$

Let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ denote the sieve generated by f . Since f is a universal quotient morphism, the functor U is left Kan extended from $\mathcal{C}_{/Y}^0$. Note that V is a right fibration (Proposition 4.3.6.1), so that V' is a trivial Kan fibration (Corollary 4.3.7.13). In particular, V' is a right fibration, so that the functor $U \circ V' = V \circ \tilde{U}$ is left Kan extended from the subcategory $\tilde{\mathcal{C}}_{/\tilde{Y}}^0 = V'^{-1} \mathcal{C}_{/Y}^0$ (Corollary 7.3.8.10). Since the functor V is conservative and creates colimits (Proposition 7.1.4.21), it follows that $\tilde{U}$ is also left Kan extended from $\tilde{\mathcal{C}}_{/\tilde{Y}}^0$. We conclude by observing that $\tilde{\mathcal{C}}_{/\tilde{Y}}^0$ is the sieve generated by $\tilde{f}$, so that $\tilde{f}$ is a universal quotient morphism in $\tilde{\mathcal{C}}$. $\square$

We close this section by characterizing (universal) quotient morphisms in the ∞ -category $\mathcal{S}$ of spaces.

Lemma 10.3.4.16. *Let $\mathcal{C}$ be an ∞ -category, let $\mathcal{C}' \subseteq \mathcal{C}$ be a dense full subcategory, and let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. Suppose that, for every object $C \in \mathcal{C}'$, postcomposition with $[f]$ induces a surjection $\mathrm{Hom}_{\mathrm{h}\mathcal{C}}(C, X) \rightarrow \mathrm{Hom}_{\mathrm{h}\mathcal{C}}(C, Y)$. Then f is a universal quotient morphism.* 04YC

Proof. Our assumption that $\mathcal{C}'$ is dense guarantees that the identity functor $\mathcal{C} \rightarrow \mathcal{C}$ is left Kan extended from $\mathcal{C}'$. Let $U : \mathcal{C}_{/Y} \rightarrow \mathcal{C}$ be the projection map and let $\mathcal{C}'_{/Y} \subseteq \mathcal{C}_{/Y}$ denote the inverse image of $\mathcal{C}'$. Since U is a right fibration (Proposition 4.3.6.1), the functor U is left Kan extended from $\mathcal{C}'_{/Y}$. Let $\mathcal{C}_{/Y}^0 \subseteq \mathcal{C}_{/Y}$ denote the sieve generated by f . Our hypothesis guarantees that $\mathcal{C}_{/Y}^0$ contains $\mathcal{C}'_{/Y}$. Applying Corollary 7.3.8.13, we conclude that U is left Kan extended from $\mathcal{C}_{/Y}^0$: that is, f is a universal quotient morphism. $\square$

Proposition 10.3.4.17. *Let $f : X \rightarrow Y$ be a map of Kan complexes. The following conditions are equivalent:* 04YD

- (1) *The map f is a universal quotient morphism in the ∞ -category $\mathcal{S}$ (Definition 10.3.4.1).*
- (2) *The map f is a quotient morphism in the ∞ -category $\mathcal{S}$ (Definition 10.3.2.1).*
- (3) *The map f is 0-connective: that is, it induces a surjection $\pi_0(f) : \pi_0(X) \rightarrow \pi_0(Y)$.*

Proof. The implication (1) $\Rightarrow$ (2) is a special case of Corollary 10.3.4.10. We next show that (2) implies (3). Assume that f is a quotient morphism, so that Y can be identified with the geometric realization of the Čech nerve $\check{C}(X/Y)_\bullet$ in the ∞ -category $\mathcal{S}$ (Proposition 10.3.2.4). Note that the functor

$$\mathcal{S} \rightarrow \mathbf{N}_\bullet(\mathrm{Set}) \quad S \mapsto \pi_0(S)$$

preserves the formation of geometric realizations (since it is left adjoint to the inclusion functor). It follows that $\pi_0(Y)$ can be identified with the geometric realization of $\pi_0(\check{C}(X/Y)_\bullet)$ in the category of sets: that is, with the coequalizer of the projection maps $\pi_0(X \times_Y X) \rightrightarrows \pi_0(X)$ (see Corollary 10.2.2.12). In particular, the tautological map $\pi_0(X) \rightarrow \pi_0(Y)$ is surjective.

We now show that (3) implies (1). Assume that condition (3) is satisfied. For every contractible Kan complex C , the composition map $\mathrm{Hom}_{\mathrm{h}\mathcal{S}}(C, X) \xrightarrow{[f] \circ} \mathrm{Hom}_{\mathrm{h}\mathcal{S}}(C, Y)$ can be identified with $\pi_0(f)$, and is therefore surjective. Since the contractible Kan complexes span a dense subcategory of $\mathcal{S}$ (Example 8.4.2.3), Lemma 10.3.4.16 implies that f is a universal quotient morphism. $\square$

10.3.5 Regular ∞ -Categories

04YE We now formulate an ∞ -categorical counterpart of Definition 10.3.0.6.

04YF **Definition 10.3.5.1.** Let $\mathcal{C}$ be an ∞ -category. We say that $\mathcal{C}$ is *regular* if it satisfies the following conditions:

- (1) The ∞ -category $\mathcal{C}$ admits finite limits.
- (2) The ∞ -category $\mathcal{C}$ has images. That is, every morphism $f : X \rightarrow Y$ of $\mathcal{C}$ can be extended to a 2-simplex

$$\begin{array}{ccc} & Y_0 & \\ q \nearrow & & \searrow i \\ X & \xrightarrow{f} & Y, \end{array}$$

where q is a quotient morphism and i is a monomorphism.

- (3) The collection of quotient morphisms in $\mathcal{C}$ is closed under pullback. That is, for every pullback diagram

$$\begin{array}{ccc} X' & \longrightarrow & X \\ \downarrow f' & & \downarrow f \\ Y' & \longrightarrow & Y \end{array}$$

of $\mathcal{C}$, if f is a quotient morphism, then f' is also a quotient morphism.

04YG **Example 10.3.5.2.** Let $\mathcal{C}$ be a category. Then $\mathcal{C}$ is regular (in the sense of Definition 10.3.0.6) if and only if $\mathbf{N}_\bullet(\mathcal{C})$ is a regular ∞ -category (in the sense of Definition 10.3.5.1). See Corollary 10.3.2.7.

Definition 10.3.5.1 admits a number of reformulations.

04YH **Proposition 10.3.5.3.** Let $\mathcal{C}$ be an ∞ -category which has images and admits finite limits. The following conditions are equivalent:

- (1) The ∞ -category $\mathcal{C}$ is regular: that is, the collection of quotient morphisms in $\mathcal{C}$ is closed under pullbacks.
- (2) Every quotient morphism in $\mathcal{C}$ is a universal quotient morphism.
- (3) Every morphism $f : X \rightarrow Y$ of $\mathcal{C}$ can be realized as the composition of a universal quotient morphism $q : X \twoheadrightarrow Y_0$ and a monomorphism $i : Y_0 \hookrightarrow Y$.

(4) For every pullback diagram

$$\begin{array}{ccc} X' & \xrightarrow{f'} & Y' \\ \downarrow & & \downarrow u \\ X & \xrightarrow{f} & Y, \end{array} \quad \begin{array}{l} \text{04YJ} \\ (10.14) \end{array}$$

the image $\text{im}(f')$ coincides with $u^{-1}(\text{im}(f))$ (as an element of the set $\text{Sub}(Y')$).

Proof. The equivalence of (1) $\Leftrightarrow$ (2) is a special case of Corollary 10.3.4.8, and the implication (2) $\Rightarrow$ (3) is immediate from the definitions. We next show that (3) implies (4). Fix a diagram of the form (10.14). If condition (3) is satisfied, then we can choose a diagram

$$\begin{array}{ccccc} & & & & Y' \\ & & & & \downarrow u \\ X & \xrightarrow{q} & Y_0 & \xrightarrow{i} & Y \end{array}$$

in the ∞ -category $\mathcal{C}$ where q is a universal quotient morphism, i is a monomorphism, and the lower vertical composition coincides with f . Since $\mathcal{C}$ admits finite limits, this diagram admits a right Kan extension

$$\begin{array}{ccccc} Y' \times_Y X & \xrightarrow{q'} & Y' \times_Y Y_0 & \xrightarrow{i'} & Y' \\ \downarrow & & \downarrow & & \downarrow u \\ X & \xrightarrow{q} & Y_0 & \xrightarrow{i} & Y, \end{array} \quad \begin{array}{l} \text{04YK} \\ (10.15) \end{array}$$

so that the right square and outer rectangle are pullback diagrams. By construction, the inverse image $u^{-1}(\text{im}(f))$ is the isomorphism class of the fiber product $Y' \times_Y Y_0$ (regarded as an object of the ∞ -category $\mathcal{C}_{/Y'}$ via the morphism i'). On the other hand, the uniqueness of limits guarantees that $Y' \times_Y X$ is isomorphic to X' as an object of $\mathcal{C}_{/Y'}$, so the image of f' coincides with the image of the composite morphism $i' \circ q'$. To prove that this image coincides with $[Y' \times_Y Y_0]$, it suffices to show that q' is a quotient morphism in $\mathcal{C}$. This follows from Corollary 10.3.4.7, since the left half of (10.15) is also a pullback square (Proposition 7.6.2.28).

We now complete the proof by showing that (4) implies (1). Suppose we are given a pullback square (10.14), where f is a quotient morphism; we wish to show that f' is also a

quotient morphism. By virtue of Proposition 10.3.3.6, the assumption that f is a quotient morphism guarantees that $\mathrm{im}(f) = [Y]$ is the largest element of $\mathrm{Sub}(Y)$, and we wish to show that $\mathrm{im}(f') = [Y']$ is the largest element of $\mathrm{Sub}(Y')$. This follows immediately from (4), since the inverse image construction $u^{-1} : \mathrm{Sub}(Y) \rightarrow \mathrm{Sub}(Y')$ preserves largest elements (see Construction 9.6.4.32). $\square$

04YL **Remark 10.3.5.4.** Let $\mathcal{C}$ be an ∞ -category which has images and admits finite limits. Then, for every pullback diagram

$$\begin{array}{ccc} X' & \xrightarrow{f'} & Y' \\ \downarrow & & \downarrow u \\ X & \xrightarrow{f} & Y, \end{array}$$

we always have a containment $\mathrm{im}(f') \subseteq u^{-1}(\mathrm{im}(f))$ in $\mathrm{Sub}(Y')$; this follows from the characterization of $\mathrm{im}(f)$ supplied by Proposition 10.3.3.11.

04YM **Corollary 10.3.5.5.** *Let $\mathcal{C}$ be an ∞ -category which admits finite limits. Then $\mathcal{C}$ is regular if and only if every morphism $f : X \rightarrow Y$ can be obtained by composing a universal quotient morphism $q : X \twoheadrightarrow Y_0$ with a monomorphism $i : Y_0 \hookrightarrow Y$.*

04YN **Corollary 10.3.5.6.** *Let $\mathcal{S}$ denote the ∞ -category of spaces. Then $\mathcal{S}$ is a regular ∞ -category.*

Proof. Corollary 7.4.1.3 guarantees that $\mathcal{S}$ admits finite limits. By virtue of Corollary 10.3.5.5, it will suffice to show that every map of Kan complexes $f : X \rightarrow Y$ factors as a composition $i \circ q$, where $q : X \twoheadrightarrow Y_0$ is a universal quotient morphism in $\mathcal{S}$ and $i : Y_0 \hookrightarrow Y$ is a monomorphism in $\mathcal{S}$. For this, we can take $i : Y_0 \hookrightarrow Y$ to be the inclusion of the essential image of f (which is a monomorphism by Example 9.6.4.10), and $q : X \rightarrow Y_0$ to be the restriction of f (which is a universal quotient morphism by Proposition 10.3.4.17). $\square$

04YP **Remark 10.3.5.7.** Let $f : X \rightarrow Y$ be a morphism of Kan complexes and let $Y_0 \subseteq Y$ be its essential image. The proof of Corollary 10.3.5.6 shows that Y_0 is an image of f in the ∞ -category $\mathcal{S}$.

04YQ **Warning 10.3.5.8.** Let $\mathcal{QC}$ denote the ∞ -category of (small) ∞ -categories. Then $\mathcal{QC}$ contains quotient morphisms which are not universal quotient morphisms (see Variant 10.3.2.17). In particular, $\mathcal{QC}$ is not regular.

04YR **Proposition 10.3.5.9.** *Let $\mathcal{C}$ be a regular ∞ -category. Then, for every object $Z \in \mathcal{C}$, the slice ∞ -category $\mathcal{C}_{/Z}$ is regular.*

Proof. It follows from Remark 7.1.3.12 that the ∞ -category $\mathcal{C}_{/Z}$ admits finite limits. By virtue of Corollary 10.3.5.5, it will suffice to show that every morphism $\tilde{f} : \tilde{X} \rightarrow \tilde{Y}$ can be realized as the composition of a universal quotient morphism $\tilde{X} \twoheadrightarrow \tilde{Y}_0$ with a monomorphism $\tilde{Y}_0 \hookrightarrow \tilde{Y}$. Let $f : X \rightarrow Y$ denote the image of $\tilde{f}$ in the ∞ -category $\mathcal{C}$. Since $\mathcal{C}$ is regular, we can choose a 2-simplex σ :

$$\begin{array}{ccc} & Y_0 & \\ q \nearrow & & \searrow i \\ X & \xrightarrow{f} & Y \end{array}$$

of $\mathcal{C}$, where q is a universal quotient morphism and i is a monomorphism. The inclusion map $N_\bullet(\{0 < 2\}) \hookrightarrow \Delta^2$ is right anodyne (Lemma 4.3.7.8), so we can lift σ to a 2-simplex

$$\begin{array}{ccc} & \tilde{Y}_0 & \\ \tilde{q} \nearrow & & \searrow \tilde{i} \\ \tilde{X} & \xrightarrow{\tilde{f}} & \tilde{Y} \end{array}$$

in the ∞ -category $\mathcal{C}_{/Z}$. We conclude by observing that $\tilde{i}$ is a monomorphism (Remark 9.6.4.24) and $\tilde{q}$ is a universal quotient morphism (Proposition 10.3.4.15). $\square$

We now study functors between regular ∞ -categories.

Definition 10.3.5.10. Let $\mathcal{C}$ and $\mathcal{D}$ be regular ∞ -categories. We say that a functor 04YS $F : \mathcal{C} \rightarrow \mathcal{D}$ is *regular* if it preserves finite limits and carries quotient morphisms of $\mathcal{C}$ to quotient morphisms of $\mathcal{D}$.

Remark 10.3.5.11. Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories which preserves pullbacks. 04YT Then F carries monomorphisms in $\mathcal{C}$ to monomorphisms in $\mathcal{D}$ (Proposition 9.6.4.21). In particular, for every object $Y \in \mathcal{C}$, the functor F carries subobjects of Y to subobjects of $F(Y)$, and therefore induces a map of partially ordered sets $\text{Sub}(Y) \rightarrow \text{Sub}(F(Y))$.

Proposition 10.3.5.12. Let $\mathcal{C}$ and $\mathcal{D}$ be ∞ -categories which have images, and let $F : \mathcal{C} \rightarrow \mathcal{D}$ 04YU be a functor which preserves pullback squares. The following conditions are equivalent:

- (1) The functor F carries quotient morphisms in $\mathcal{C}$ to quotient morphisms in $\mathcal{D}$.

(2) For every 2-simplex σ :

$$\begin{array}{ccc} & Y_0 & \\ q \nearrow & & \searrow i \\ X & \xrightarrow{f} & Y \end{array}$$

in the ∞ -category $\mathcal{C}$ which exhibit Y_0 as an image of f , the 2-simplex $F(\sigma)$ exhibits $F(Y_0)$ as an image of $F(f)$ in the ∞ -category $\mathcal{D}$.

(3) For every morphism $f : X \rightarrow Y$ in $\mathcal{C}$, the map $\text{Sub}(Y) \rightarrow \text{Sub}(F(Y))$ of Remark 10.3.5.11 carries $\text{im}(f)$ to $\text{im}(F(f))$.

Proof. The implication (1) $\Rightarrow$ (2) follows from the observation that F preserves monomorphisms (Proposition 9.6.4.21), and the implication (2) $\Rightarrow$ (3) is immediate from the definitions. We will complete the proof by showing that (3) implies (1). Let $f : X \rightarrow Y$ be a quotient morphism in $\mathcal{C}$; we wish to show that $F(f)$ is a quotient morphism in $\mathcal{D}$. By virtue of Proposition 10.3.3.6, our hypothesis can be reformulated as an equality $\text{im}(f) = [Y]$ in the partially ordered set $\text{Sub}(Y)$, and we wish to prove an equality $\text{im}(F(f)) = [F(Y)]$ in the partially ordered set $\text{Sub}(F(Y))$. This is clear, since the map $\text{Sub}(Y) \rightarrow \text{Sub}(F(Y))$ preserves largest elements (see Remark 10.3.5.11). $\square$

04YV **Remark 10.3.5.13.** Let $\mathcal{C}$ and $\mathcal{D}$ be ∞ -categories with images, and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor which preserves pullback diagrams. For any morphism $f : X \rightarrow Y$ of $\mathcal{C}$, we always have an inclusion $F(\text{im}(f)) \subseteq \text{im}(F(f))$ in the partially ordered set $\text{Sub}(F(Y))$.

04YW **Corollary 10.3.5.14.** Let $\mathcal{C}$ and $\mathcal{D}$ be regular ∞ -categories, and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor which preserves finite limits. Then F is regular if and only if, for every morphism $f : X \rightarrow Y$ in the ∞ -category $\mathcal{C}$, the map $\text{Sub}(Y) \rightarrow \text{Sub}(F(Y))$ of Remark 10.3.5.11 carries $\text{im}(f)$ to $\text{im}(F(f))$.

04YX **Example 10.3.5.15.** Let $\mathcal{C}$ be a regular ∞ -category. Then, for every object $X \in \mathcal{C}$, the slice ∞ -category $\mathcal{C}_{/X}$ is also regular (Proposition 10.3.5.9). Moreover, for every morphism $f : X \rightarrow Y$ of $\mathcal{C}$, Proposition 7.6.2.24 guarantees that there exists a functor

$$f^* : \mathcal{C}_{/Y} \rightarrow \mathcal{C}_{/X} \quad Z \mapsto X \times_Y Z$$

given by pullback along f . The functor f^* is regular: it preserves finite limits since it is right adjoint to the postcomposition functor $(f \circ \bullet) : \mathcal{C}_{/X} \rightarrow \mathcal{C}_{/Y}$, and preserves quotient morphisms by virtue of Proposition 10.3.5.3.

Proposition 10.3.5.16. *Let $\mathcal{C}$ and $\mathcal{D}$ be ∞ -categories which admit finite limits and let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor which preserves finite limits and geometric realizations of simplicial objects. Then F carries quotient morphisms of $\mathcal{C}$ to quotient morphisms of $\mathcal{D}$. In particular, if the ∞ -categories $\mathcal{C}$ and $\mathcal{D}$ are regular, then the functor F is regular.* 04YY

Proof. Let $f : X \rightarrow Y$ be a quotient morphism in $\mathcal{C}$; we wish to show that $F(f)$ is a quotient morphism in $\mathcal{D}$. Let $\check{C}_\bullet(X/Y) : N_\bullet(\Delta_+^{\text{op}}) \rightarrow \mathcal{C}$ be a Čech nerve of f (Notation 10.2.5.5). Since f is a quotient morphism (Remark 10.3.4.2), $\check{C}_\bullet(X/Y)$ is a colimit diagram in $\mathcal{C}$ (Proposition 10.3.2.4). Our assumption that F preserves geometric realizations guarantees that $F \circ \check{C}_\bullet(X/Y)$ is a colimit diagram in the ∞ -category $\mathcal{D}$. Since F preserves finite limits, $F \circ \check{C}_\bullet(X/Y)$ is a Čech nerve of the morphism $F(f) : F(X) \rightarrow F(Y)$. Applying Proposition 10.3.2.4 again, we deduce that $F(f)$ is a quotient morphism in $\mathcal{D}$. $\square$

We now record some closure properties for the collection of regular ∞ -categories.

Proposition 10.3.5.17. *Let $\mathcal{C}$ be an ∞ -category which admits pullbacks, let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a full subcategory which is closed under the formation of pullbacks, and let $q : X \rightarrow Y$ be a morphism in $\mathcal{C}_0$. If q is a quotient morphism in $\mathcal{C}$, then it is also a quotient morphism in $\mathcal{C}_0$. If q is a universal quotient morphism in $\mathcal{C}$, then it is also a universal quotient morphism in $\mathcal{C}_0$.* 04YZ

Proof. Assume that q is a quotient morphism in $\mathcal{C}$; we will show that it is also a quotient morphism in $\mathcal{C}_0$ (the analogous assertion for universal quotient morphisms then follows from the criterion of Corollary 10.3.4.7). Since $\mathcal{C}$ admits pullbacks and $\mathcal{C}_0$ is stable under the formation of pullbacks, it follows that $\mathcal{C}_0$ also admits pullbacks. Applying Proposition 10.2.5.6, we deduce that q admits a Čech nerve $\check{C}_\bullet(X/Y) : N_\bullet(\Delta_+^{\text{op}}) \rightarrow \mathcal{C}_0$, which is also a Čech nerve of q in the ∞ -category $\mathcal{C}$. Since q is a quotient morphism, $\check{C}_\bullet(X/Y)$ is a colimit diagram in $\mathcal{C}$ (Proposition 10.3.2.4). It follows that $\check{C}_\bullet(X/Y)$ is also a colimit diagram in $\mathcal{C}_0$, so that q is a quotient morphism in $\mathcal{C}_0$. $\square$

Corollary 10.3.5.18. *Let $\mathcal{C}$ be a regular ∞ -category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a full subcategory which is closed under finite limits. Assume that, for every morphism f of $\mathcal{C}_0$, the image $\text{im}(f)$ (formed in the ∞ -category $\mathcal{C}$) can be chosen to belong to $\mathcal{C}_0$. Then $\mathcal{C}_0$ is also regular.* 04Z0

Proof. Let $f : X \rightarrow Y$ be a morphism in $\mathcal{C}$. Since $\mathcal{C}$ is regular, f can be factored as the composition of a universal quotient morphism $q : X \twoheadrightarrow Y_0$ with a monomorphism $i : Y_0 \hookrightarrow Y$. If X and Y belong to $\mathcal{C}_0$, then our assumption guarantees that we can arrange that Y_0 is also contained in $\mathcal{C}_0$. In this case, i is also a monomorphism in the ∞ -category $\mathcal{C}_0$, and Proposition 10.3.5.17 guarantees that q is a universal quotient morphism in the subcategory $\mathcal{C}_0$. Allowing f to vary and invoking Corollary 10.3.5.5, we conclude that $\mathcal{C}_0$ is regular. $\square$

04Z1 **Proposition 10.3.5.19.** *Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of ∞ -categories which admits a fully faithful right adjoint $G : \mathcal{D} \rightarrow \mathcal{C}$. Suppose that the ∞ -category $\mathcal{C}$ is regular and that F preserves finite limits. Then the ∞ -category $\mathcal{D}$ is also regular, and F is a regular functor.*

Proof. Since the functor F has a right adjoint, it preserves geometric realizations of simplicial objects (Corollary 7.1.4.23). Applying Proposition 10.3.5.16, we deduce that the functor F carries quotient morphisms in $\mathcal{C}$ to quotient morphisms in $\mathcal{D}$. It will therefore suffice to show that $\mathcal{D}$ is regular.

It follows from Corollary 7.1.4.28 (together with Corollary 6.2.2.25) that the ∞ -category $\mathcal{D}$ admits finite limits. We next show that every morphism $v : D \rightarrow D'$ in $\mathcal{D}$ has an image. Let $\epsilon : (F \circ G) \rightarrow \text{id}_{\mathcal{D}}$ be the counit of an adjunction between F and G . Since G is fully faithful, the natural transformation ϵ is an isomorphism. We can therefore replace v by the morphism $(F \circ G)(v)$, and thereby reduce to the case where $v = F(u)$ for some morphism $u : C \rightarrow C'$ in $\mathcal{C}$. In this case, our assumption that $\mathcal{C}$ has images guarantees that we can factor u as a composition $C \xrightarrow{q} C'_0 \xrightarrow{i} C'$, where q is a quotient morphism and i is a monomorphism (in the ∞ -category $\mathcal{C}$). It follows that v can be written as the composition of $F(q)$ (which is a quotient morphism in $\mathcal{D}$, as noted above) with $F(i)$ (which is a monomorphism in $\mathcal{D}$ by virtue of Proposition 9.6.4.21). In particular, the object $F'(C_0)$ is an image of v .

We now complete the proof by showing that if

04Z2

$$\begin{array}{ccc} X' & \xrightarrow{f'} & Z' \\ \downarrow & & \downarrow g \\ X & \xrightarrow{f} & Z \end{array} \quad (10.16)$$

is a pullback diagram in $\mathcal{C}$ where f is a quotient morphism, then f' is also a quotient morphism. Since $\mathcal{C}$ is regular, we can choose a 2-simplex

$$\begin{array}{ccc} & Y & \\ q \nearrow & & \searrow \\ G(X) & \xrightarrow{G(f)} & G(Z), \end{array}$$

which exhibits Y as an image of $G(f)$. It follows that $F(\sigma)$ exhibits $F(Y)$ as an image of the morphism $(F \circ G)(f)$ in the ∞ -category $\mathcal{D}$. Note that $(F \circ G)(f)$ is isomorphic to f (as an object of $\text{Fun}(\Delta^1, \mathcal{D})$), and is therefore a quotient morphism (Corollary 10.3.2.12). Applying Proposition 10.3.3.6, we conclude that $F(i)$ is an isomorphism in $\mathcal{D}$.

Amalgamating the 2-simplex σ with $G(g)$, we obtain a diagram

$$\begin{array}{ccccc} & & & & G(Z') \\ & & & & \downarrow G(g) \\ G(X) & \xrightarrow{q} & Y & \xrightarrow{i} & G(Z) \end{array}$$

in the ∞ -category $\mathcal{C}$. Since $\mathcal{C}$ admits finite limits, this diagram admits a right Kan extension

$$\begin{array}{ccccccc} G(X) \times_{G(Z)} G(Z') & \xrightarrow{q'} & Y \times_{G(Z)} G(Z') & \xrightarrow{i'} & G(Z') & & \\ \downarrow & & \downarrow & & \downarrow g & & \\ G(X) & \xrightarrow{q} & Y & \xrightarrow{i} & G(Z), & & \end{array} \quad (10.17) \quad 04Z3$$

so that the square on the right and the outer rectangle are pullback squares. Note that, after applying the functor F , the outer rectangle of this diagram is isomorphic to (10.16). We are therefore reduced to showing that the functor F carries the upper horizontal composition in (10.17) to a quotient morphism in $\mathcal{D}$. Since F preserves pullback squares, $F(i')$ is a pullback of $F(i)$ and is therefore an isomorphism (Corollary 7.6.2.27). Using Corollary 10.3.2.12, we are reduced to showing that $F(q')$ is a quotient morphism in $\mathcal{D}$. In fact, we claim that q' is a pullback morphism of $\mathcal{C}$. This follows from our assumption that $\mathcal{C}$ is regular, since q is a quotient morphism by construction and the left half the diagram (10.17) is a pullback square (Proposition 7.6.2.28). $\square$

Corollary 10.3.5.20. *Let $\mathcal{C}$ be a regular ∞ -category and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a reflective subcategory, 04Z4 so that the inclusion functor $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ admits a left adjoint $L : \mathcal{C} \rightarrow \mathcal{C}_0$. If the functor L preserves finite limits, then $\mathcal{C}_0$ is a regular ∞ -category and L is a regular functor.*
