## A1 List of Countries

Table A1 lists all countries in our main sample used to estimate the baseline specification of our model.

Table A1: Main Sample

| Country | Years | Notes | Country | Years | Notes |
| :---: | :---: | :---: | :---: | :---: | :---: |
| United States | 1951-2000 |  | Canada | 1951-2000 |  |
| Cuba | 1951-2000 |  | Dominican Republic | 1951-2000 |  |
| Jamaica | 1964-2000 |  | Trinidad and Tobago | 1964-2000 |  |
| Mexico | 1951-2000 |  | Guatemala | 1951-2000 |  |
| Honduras | 1951-2000 |  | El Salvador | 1951-2000 |  |
| Nicaragua | 1951-2000 |  | Costa Rica | 1951-2000 |  |
| Panama | 1951-2000 |  | Colombia | 1951-2000 |  |
| Venezuela | 1951-2000 |  | Ecuador | 1951-2000 |  |
| Peru | 1951-2000 |  | Brazil | 1951-2000 |  |
| Bolivia | 1951-2000 |  | Paraguay | 1951-2000 |  |
| Chile | 1951-2000 |  | Argentina | 1951-2000 |  |
| Uruguay | 1951-2000 |  | United Kingdom | 1951-2000 |  |
| Ireland | 1951-2000 |  | Netherlands | 1951-2000 |  |
| Belgium | 1951-2000 |  | France | 1951-2000 |  |
| Switzerland | 1951-2000 |  | Spain | 1951-2000 |  |
| Portugal | 1951-2000 |  | Germany | $1951-2000$ | Federal Republic of Germany from 1951-1990. |
| Poland | 1951-2000 |  | Austria | 1951-2000 |  |
| Hungary | 1951-2000 |  | Czech Republic | 1951-2000 | Czechoslovakia from 1951-1992. |
| Slovakia | 1994-2000 |  | Italy | 1951-2000 |  |
| Albania | 1951-2000 |  | Macedonia | 1993-2000 |  |
| Croatia | 1992-2000 |  | Yugoslavia | 1951-1991 |  |
| Bosnia and Herzegovina | 1993-2000 |  | Slovenia | 1992-2000 |  |
| Greece | 1951-2000 |  | Bulgaria | 1951-2000 |  |
| Moldova | 1992-2000 |  | Romania | 1951-2000 |  |
| Russia | 1951-2000 | U.S.S.R. from 1951-1991. | Estonia | 1993-2000 |  |
| Latvia | 1992-2000 |  | Lithuania | 1992-2000 |  |
| Ukraine | 1992-2000 |  | Belarus | 1993-2000 |  |
| Armenia | 1993-2000 |  | Georgia | 1993-2000 |  |
| Azerbaijan | 1993-2000 |  | Finland | 1951-2000 |  |
| Sweden | 1951-2000 |  | Norway | 1951-2000 |  |
| Denmark | 1951-2000 |  | Republic of Guinea-Bissau | 1976-2000 |  |
| Equatorial Guinea | 1969-2000 |  | Gambia | 1967-2000 |  |
| Mali | 1962-2000 |  | Senegal | 1962-2000 |  |
| Benin | 1961-2000 |  | Mauritania | 1962-2000 |  |
| Niger | 1962-2000 |  | Côte D'Ivoire | 1962-2000 |  |
| Republic of Guinea | 1960-2000 |  | BurkinaFaso | 1962-2000 |  |
| Liberia | 1951-2000 |  | Sierra Leone | 1963-2000 |  |
| Ghana | 1958-2000 |  | Togo | 1962-2000 |  |
| Cameroon | 1961-2000 |  | Nigeria | 1962-2000 |  |
| Gabon | 1962-2000 |  | Central African Republic | 1962-2000 |  |
| Chad | 1962-2000 |  | Republic of the Congo | 1962-2000 |  |
| Zaire | 1962-2000 | Congo-Léopoldville from 1962-1965, Democratic Republic of Congo from 1997-2000. | Uganda | 1964-2000 |  |
| Kenya | 1965-2000 |  | Tanzania | 1963-2000 |  |
| Burundi | 1964-2000 |  | Rwanda | 1963-2000 |  |
| Somalia | 1962-1991 |  | Djibouti | 1979-2000 |  |
| Ethiopia | 1994-2000 |  | Angola | 1977-2000 |  |
| Mozambique | 1977-2000 |  | Zambia | 1966-2000 |  |
| Zimbabwe | 1967-2000 |  | Malawi | 1966-2000 |  |
| South Africa | 1951-2000 |  | Namibia | 1992-2000 |  |
| Lesotho | 1968-2000 |  | Botswana | 1968-2000 |  |
| Swaziland | 1970-2000 |  | Madagascar | 1962-2000 |  |
| Comoro Islands | 1977-2000 |  | Mauritius | 1970-2000 |  |
| Morocco | 1958-2000 |  | Algeria | 1964-2000 |  |
| Tunisia | 1951-2000 |  | Libya | 1953-2000 |  |
| Sudan | 1957-2000 |  | Iran | 1951-2000 |  |
| Turkey | 1951-2000 |  | Iraq | 1951-2000 |  |
| Egypt | 1951-2000 |  | Syria | 1951-2000 |  |
| Lebanon | 1951-2000 |  | Jordan | 1951-2000 |  |
| Israel | 1951-2000 |  | Saudi Arabia | 1951-2000 |  |
| Kuwait | 1952-2000 |  | Bahrain | 1973-2000 |  |
| Qatar | 1973-2000 |  | United Arab Emirates | 1973-2000 |  |

## A2 Preliminary Evidence

To motivate our model, we estimate a pair of reduced-form regressions. The purpose is to demonstrate two empirical patterns underpinning our structural approach: (i) democracy adoption systematically covaries with observed differences in economic performance between neighboring democracies and autocracies-which is suggestive of the learning process we model-and (ii) economic growth has a differential impact on elite turnover under democracy versus autocracy.

First, we estimate the following linear probability model via ordinary least squares:

$$
\begin{equation*}
D_{i, t}=\phi_{0}+\phi_{1} D_{i, t-1}+\phi_{2}\left[\bar{y}_{i, t-1}^{D=1}-\bar{y}_{i, t-1}^{D=0}\right]+\phi_{3} \bar{D}_{i, t-1}+u_{i, t}, \tag{A1}
\end{equation*}
$$

where $\bar{y}_{i, t-1}^{D=1}$ and $\bar{y}_{i, t-1}^{D=0}$ are weighted averages of past GDP per capita growth rates among country $i$ 's democratic and autocratic neighbors, respectively. ${ }^{1}$ Thus, $\bar{y}_{i, t-1}^{D=1}-\bar{y}_{i, t-1}^{D=0}$ proxies for beliefs in country $i$ about the impact of democracy on economic growth. We vary the size of $i$ 's effective neighborhood by setting the decay parameter equal to the estimated value from our structural model $(\gamma=0.4234)$ as well as twice $(2 \gamma)$ and half this value $\left(\frac{1}{2} \gamma\right)$. Furthermore, we control for $\bar{D}_{i, t-1}$, the weighted proportion of democracies in $i$ 's neighborhood.

If $\phi_{2} \neq 0$, then, consistent with our model, democracy adoption systematically covaries with observed growth differences in democratic versus autocratic neighbors. We evaluate this hypothesis in Table A2, which shows that, across specifications and spatial weights, the reduced-form evidence is indeed consistent with our structural estimates: as $\phi_{2}>0$, the likelihood of democracy increases with superior economic performance in democracies.

Second, to motivate incumbents' objective function in our model, we show that the effect of GDP growth on their likelihood of retaining power in the subsequent period is heterogenous

Notes. Ordinary least squares estimates from regression (A1). All models include country fixed effects. Standard errors in parentheses.
across democracies and autocracies, with its impact in democracies being consistently larger. Specifically, we estimate the following linear probability model via least squares:

$$
\begin{equation*}
\operatorname{Pr}\left(\text { RetainPower }_{i, t+1} \mid y_{i, t}, D_{i, t}\right)=\lambda_{0}+\lambda_{1} y_{i, t}+\lambda_{2} D_{i, t}+\lambda_{3} y_{i, t} \times D_{i, t} . \tag{A2}
\end{equation*}
$$

Of course, given the selection into or out of democracy we model, estimates of $\lambda$ will be inconsistent. To address this without imposing additional structure, we use $\bar{y}_{i, t-1}^{D=1}, \bar{y}_{i, t-1}^{D=0}$, and $\bar{D}_{i, t-1}$ from (A1) to build instruments for the regressors in (A2). ${ }^{2}$ That is, in line with our assumption that beliefs have no direct impact on outcomes (other than through institutional choices), if we correctly measured beliefs, we could obtain consistent estimates of $\lambda$ via twostage least squares. Since we view $\bar{y}_{i, t-1}^{D=1}$ and $\bar{y}_{i, t-1}^{D=0}$ only as rough proxies for beliefs, however, we take the instrumental-variables estimates of $\lambda_{1}$ and $\lambda_{3}$ with a grain of salt.

Estimates of $\lambda_{1}$ and $\lambda_{1}+\lambda_{3}$ measure the effects of economic growth on elite survival under autocracy and democracy, respectively, while $\lambda_{2}$ gives the difference in baseline survival under democracy (the average of $-f_{i}$ in our structural model). Ordinary and two-stage least

Notes. Ordinary (OLS) and two-stage least squares (2SLS) estimates from regression (A2). All models include country fixed effects. Standard errors in parentheses.
squares estimates are presented in Table A3. Across specifications, we find that democracies consistently reward incumbents for high rates of growth more than autocracies. Moreover, the two-stage least squares results are consistent with our structural estimates in that growth is stabilizing for incumbents under democracy but not under autocracy. These estimates are imprecise, however, given that the instruments are only rough proxies for the learning process we model.

## A2.1 Growth in Democracies Versus Autocracies

Figure A1 illustrates the variation in the data that drives our main results by plotting the evolution of the difference in growth rates in democracies versus autocracies. The plot shows that, following the oil crisis, democracies experienced a markedly superior recovery. This underlies the sharp revision of beliefs and subsequent transitions to democracy that characterize the most consequential period in our sample.

Figure A1: Difference in Average Growth Rates in Democracies Versus Autocracies

## A3 Likelihood of the Data

Recall that $W^{T} \equiv\left\{I_{t}, y_{t}, D_{t}, X_{t}\right\}_{t=1}^{T}$ denotes the set of all data available up to period $T$. With a slight abuse of notation-using $\mathcal{L}$ to denote arbitrary densities of the data-the likelihood function can be written as

$$
\mathcal{L}\left(W^{T} \mid \varphi\right)=\prod_{t=1}^{T} \mathcal{L}\left(W_{t} \mid W^{t-1}, \varphi\right)
$$

where $W_{t} \equiv\left\{I_{t}, y_{t}, D_{t}, X_{t}\right\}$ collects the data generated in period $t$. As discussed in the paper, we assume that observed outcomes are only affected by actual choices and not by the beliefs that led to those choices. That is, transitions of power $\left(I_{t}\right)$, GDP growth $\left(y_{t}\right)$, and other economic and political characteristics of countries $\left(X_{t}\right)$ are shaped by realized institutions $\left(D_{t}\right)$, but they are not directly affected by beliefs about the potential effects of transitioning
into or out of democracy. Formally, this assumption allows us to write

$$
\begin{aligned}
\mathcal{L}\left(W_{t} \mid W^{t-1}, \varphi\right)= & \mathcal{L}\left(I_{t}, y_{t}, D_{t}, X_{t} \mid W^{t-1}, \varphi\right) \\
= & \mathcal{L}\left(I_{t} \mid y_{t}, D_{t}, X_{t}, W^{t-1}\right) \mathcal{L}\left(y_{t} \mid D_{t}, X_{t}, W^{t-1}\right) \cdots \\
& \mathcal{L}\left(D_{t} \mid X_{t}, W^{t-1}, \varphi\right) \mathcal{L}\left(X_{t} \mid W^{t-1}\right),
\end{aligned}
$$

which implies that $\mathcal{L}\left(W^{T} \mid \varphi\right) \propto \prod_{t=1}^{T} \mathcal{L}\left(D_{t} \mid X_{t}, W^{t-1}, \varphi\right)$.
To compute $\mathcal{L}\left(D_{t} \mid X_{t}, W^{t-1}, \varphi\right)$, notice from (5) in the paper that, given $\left(X_{i, t}, W^{t-1}, \varphi\right)$, there is a threshold value of $\kappa_{i, t}$ - the realized shock in period $t$ to the political cost of democracy in country $i$-such that $D_{i, t}=1$ if and only if $\kappa_{i, t}$ falls below the threshold. This threshold value, denoted $\bar{\kappa}_{i, t}\left(X_{i, t}, W^{t-1}, \varphi\right)$, is defined implicitly by

$$
\begin{array}{r}
E_{i, t-1}\left[\frac{\exp \left(\alpha_{i}+\theta^{D=1}\left(\beta_{i}^{D=1}+\epsilon_{i, t}\right)-f_{i}-X_{i, t}^{\prime} \xi-\bar{\kappa}_{i, t}\left(X_{i, t}, W^{t-1}, \varphi\right)\right)}{1+\exp \left(\alpha_{i}+\theta^{D=1}\left(\beta_{i}^{D=1}+\epsilon_{i, t}\right)-f_{i}-X_{i, t}^{\prime} \xi-\bar{\kappa}_{i, t}\left(X_{i, t}, W^{t-1}, \varphi\right)\right)}\right]  \tag{A3}\\
\quad=E_{i, t-1}\left[\frac{\exp \left(\alpha_{i}+\theta^{D=0}\left(\beta_{i}^{D=0}+\epsilon_{i, t}\right)\right)}{1+\exp \left(\alpha_{i}+\theta^{D=0}\left(\beta_{i}^{D=0}+\epsilon_{i, t}\right)\right)}\right] .
\end{array}
$$

Since $\kappa_{i, t}$ is distributed independently across countries, the likelihood can be written as

$$
\mathcal{L}\left(W^{T} \mid \varphi\right) \propto \prod_{t=1}^{T} \prod_{i=1}^{n} \mathcal{L}\left(D_{i, t} \mid X_{i, t}, W^{t-1}, \varphi\right)
$$

where

$$
\mathcal{L}\left(D_{i, t} \mid X_{i, t}, W^{t-1}, \varphi\right)=\Phi\left(\frac{\bar{\kappa}_{i, t}\left(X_{i, t}, W^{t-1}, \varphi\right)}{\varsigma_{i}}\right)^{D_{i, t}}\left[1-\Phi\left(\frac{\bar{\kappa}_{i, t}\left(X_{i, t}, W^{t-1}, \varphi\right)}{\varsigma_{i}}\right)\right]^{1-D_{i, t}}
$$

and $\Phi$ denotes the standard Normal cumulative distribution function.

## A4 Prior

We set our prior over the model parameters in Table 1 as follows. We assume that

$$
\begin{aligned}
& \alpha_{i} \stackrel{\text { i.i.d. }}{\sim} N\left(\underline{\alpha}, \omega_{\alpha}^{2}\right), \\
& \theta^{D=0,1} \stackrel{\text { i.i.d. }}{\sim} N\left(\underline{\theta}, \omega_{\theta}^{2}\right), \\
& \bar{\beta}_{i, 0}^{D=0} \stackrel{\text { i.i.d. }}{\sim} N\left(\underline{\beta}_{0}^{D=0}, \omega_{\beta}^{2}\right), \\
& \bar{\beta}_{i, 0}^{D=1} \stackrel{\text { i.i.d. }}{\sim} N\left(\underline{\beta}_{0}^{D=1}, \omega_{\beta}^{2}\right), \\
& v_{i} \stackrel{\text { i.i.d. }}{\sim} \operatorname{IG}\left(s_{v}, d_{v}\right), \\
& f_{i} \stackrel{\text { i.i.d. }}{\sim} N\left(\underline{f}, \omega_{f}^{2}\right), \\
& \varsigma_{i} \stackrel{\text { i.i.d. }}{\sim} \operatorname{IG}\left(s_{\varsigma}, d_{\varsigma}\right), \\
& \gamma \sim \text { Uniform, } \\
& \xi \sim \text { Uniform, }
\end{aligned}
$$

where $\operatorname{IG}(s, d)$ denotes the Inverse-Gamma distribution with shape parameter $s$ and scale parameter $d$. We calibrate our prior using pre-sample data from 1875-1950 (excluding the two world wars):

- We set $\underline{\beta}_{0}^{D=0}=0.0180$ and $\underline{\beta}_{0}^{D=1}=0.0218$, the average annual growth rates among autocracies and democracies, respectively, in the pre-sample period. We then set $\omega_{\beta}=$ 0.02, allowing for considerable uncertainty about the mean of initial beliefs.
- We select $s_{v}=3$ and $d_{v}=0.7423$ so that the prior mean and standard deviation of $v_{i} \sigma_{i}$ equal the standard deviation of average growth rates, $\bar{y}_{i}$, in the pre-sample period. A pre-sample estimate of the mean of $\sigma_{i}$ (equal to 0.0531 ) is obtained from the residuals of a regression of GDP growth on country and time fixed effects. We then set the prior mean of $v_{i}$ equal to $\sqrt{\operatorname{Var}\left(\bar{y}_{i}\right)} / 0.0531=\sqrt{0.0004} / 0.0531=0.3711$.
- We set $\underline{\theta}=0$ to adopt an agnostic starting point about whether GDP growth has a
stabilizing or destabilizing effect on elite turnover across systems of government, and we normalize $\omega_{\theta}=1$.
- To adopt an agnostic starting point regarding the political cost of democracy, we set $\underline{f}=0$. We describe our choice of $\omega_{f}$ below.
- To ensure prior belief correlations between 0 and 1 , we adopt a flat (improper) prior over $\gamma \geq 0$. For the political cost of democracy, we center the variables in $X_{i, t}$ around their sample means so that $K_{i, t}$ has an expected value of zero (in line with our agnostic view of $f_{i}$ ), and we adopt a flat (improper) prior over $\xi$.
- Letting $\overline{\theta y}_{i}$ and $\overline{K D}_{i}$ denote the within-country means of $\theta^{D=D_{i, t}} y_{i, t}$ and $K_{i, t} D_{i, t}$, respectively, and noting that $\alpha_{i}+\overline{\theta y}_{i}-\overline{D K}_{i}$ approximately equals the log-odds of staying in power in country $i$, we select $\underline{\alpha}, \omega_{\alpha}$, and $\omega_{f}$ to match the first two moments of these log-odds across countries in the pre-sample period. Since $E\left(\alpha_{i}+\overline{\theta y}_{i}-\overline{D K}_{i}\right)=\underline{\alpha}$, we set $\underline{\alpha}=1.8432$, the average log-odds in the pre-sample period. ${ }^{3}$ Noting that the variance of the log-odds among autocracies is approximately equal to $\omega_{\alpha}^{2}+\operatorname{Var}\left(\bar{y}_{i}\right)$, while the variance among democracies is approximately equal to $\omega_{\alpha}^{2}+\operatorname{Var}\left(\bar{y}_{i}\right)+\omega_{f}^{2}$, we set $\omega_{\alpha}^{2}+0.0005=0.722$ and $\omega_{\alpha}^{2}+0.0007+\omega_{f}^{2}=1.0802$, so $\omega_{\alpha}=0.8494$ and $\omega_{f}=0.5984$.
- Finally, to discourage the model from fitting the data with large (absolute) realizations of the unobserved political cost shock $\kappa_{i, t}$, we set $s_{\varsigma}=3$ and $d_{\varsigma}=0.2992$ so that $\varsigma_{i}$ has a prior mean and standard deviation of $\omega_{f} / 4=0.1496$.

## A5 Maximum-A-Posteriori Estimator: MPEC Approach

As noted in the paper, calculating $\bar{\kappa}_{i, t}\left(X_{i, t}, W^{t-1}, \varphi\right)$ from (A3) to evaluate the likelihood of the data is computationally expensive. To avoid this burden, we follow the Mathematical

[^3]Programming with Equilibrium Constraints (MPEC) approach of Su and Judd (2012) to compute our maximum-a-posteriori (MAP) estimator of $\varphi$. The idea behind this approach is simple: instead of calculating $\bar{\kappa}_{i, t}\left(X_{i, t}, W^{t-1}, \varphi\right)$ at every trial value of $\varphi$, one treats each $\bar{\kappa}_{i, t}$ as an auxiliary parameter and imposes (A3) - the optimality (or equilibrium) condition of the model-as a feasibility constraint on the log-posterior maximization program. Accordingly, we estimate $\varphi$ by solving $\max _{\varphi, \bar{\kappa}} \log \left(p\left(\varphi, \bar{\kappa} \mid W^{T}\right)\right)$ subject to the constraint that $\bar{\kappa}_{i, t}$ satisfies (A3) for all $i$ and $t$.

As shown by Su and Judd (2012), MPEC and the standard approach of directly maximizing $\log \left(p\left(\varphi \mid W^{T}\right)\right)$ yield theoretically-identical estimates of $\varphi$. Computationally, MPEC's advantage arises from the fact that modern optimization algorithms do not enforce constraints until the final iteration of the search process. Thus, the computationally expensive condition (A3) is satisfied exactly only once rather than at every trial value of $\varphi$. Moreover, for this reason, MPEC is robust to sensitivity issues that may arise from not setting a sufficiently stringent convergence criterion when computing $\bar{\kappa}_{i, t}\left(X_{i, t}, W^{t-1}, \varphi\right)$ (Dubé, Fox and $\mathrm{Su}, 2012$ ). A potential disadvantage is that, by introducing $\overline{\boldsymbol{\kappa}}$ as additional parameters, MPEC increases the size of the optimization problem. However, this concern is mitigated by the sparsity that results from each auxiliary parameter $\bar{\kappa}_{i, t}$ entering a single constraint.

To reap the computational benefits of the MPEC approach, it is essential to employ optimization software tailor-made to handle large-scale problems - with thousands of variables and nonlinear constraints. Accordingly, we implement our MPEC-MAP estimator using the industry-leading software Knitro. ${ }^{4}$ Due to memory and computational constraints-our baseline model with no covariates features 8,459 variables-our implementation relies on Knitro's Interior/Direct algorithm with their limited-memory quasi-Newton BFGS approximation of the Hessian of the Lagrangian. Nevertheless, we provide exact first derivatives of the log-posterior and constraints. ${ }^{5}$ With a 3.0 GHz machine, it takes about $5-6$ days to

[^4]estimate our model once.
To mitigate concerns about potential local maxima, for each model specification we randomly draw 5 sets of starting values for the optimization algorithm from the prior distribution of the model parameters described in Appendix A4. We then select, for each specification, the solution that achieves the highest log-posterior value. Reassuringly, there is very little divergence in solutions across starting values.

Standard errors for our parameter estimates are parametrically bootstrapped (Davison and Hinkley, 1997). Due to the considerable computational cost of estimating our model, we only compute standard errors for our baseline specification with no covariates. This has the added advantage that only estimates from the true DGP described in Footnote 36 are necessary to generate bootstrap samples.

A final notable computational challenge is that the integrals in (A3) have no closedform solution. Rather than employing a Monte Carlo approximation, which would require independent draws across all $i$ and $t$ to prevent simulation error from propagating, we rely on sparse-grid integration as implemented by Heiss and Winschel (2008). This approach is much more efficient and delivers virtually exact integral computations for integrands that are well approximated by polynomials-as is the case for the integrals in (A3). ${ }^{6}$

## A6 Coefficient Estimates: Baseline Model

Table 1 lists and describes all the parameters of our model. In our baseline specification with no covariates, the vector $\xi$ is empty. We report estimates of $\theta$ and $\gamma$ in Footnotes 31 and 34 , respectively, and estimates of $f_{i}$ for each country in Figure 3. Table A4 presents all remaining coefficient estimates for our baseline specification (standard errors in parentheses).

[^5]Table A4: Estimates of Country-Specific Parameters $\alpha_{i}, \beta_{i, 0}^{D=0}, \beta_{i, 0}^{D=1}, v_{i}$, and $\varsigma_{i}$

| Country | $\alpha_{i}$ | $\beta_{i, 0}^{D=0}$ | $\beta_{i, 0}^{D=1}$ | $v_{i}$ | $\varsigma_{i}$ | Country | $\alpha_{i}$ | $\beta_{i, 0}^{D=0}$ | $\beta_{i, 0}^{D=1}$ | $v_{i}$ | $\varsigma_{i}$ |

## A7 Additional Results

In this appendix, we describe in detail various additional results mentioned in the paper.

Model fit by world region. Figure A2 presents goodness-of-fit and out-of-sample prediction results disaggregated by four regions of the world: the Americas, Europe, Africa, and Asia-Oceania. As in Figure 1, we compare the true proportion of democracies (gray) in each region with our learning model's predictions, both in (solid blue) and out of sample (dashed blue). The top panel presents results from our baseline model with no covariates, and the bottom panel, from our model with two covariates. Notably, both specifications perform well at this, or indeed any, level of geographic aggregation. And, while not included in Figure A2 to avoid clutter, our learning model still significantly outperforms any alternative that ignores the role of learning.

Direct diffusion of democracy. To evaluate the possibility that our model's empirical success is simply an artifact of some alternative process of democratic diffusion that is indirectly picked up by our model's spatial and temporal flexibility, we construct a distanceweighted measure of how democratic each country's neighborhood is over time, and we reestimate our baseline model using this measure as a control for direct diffusion effects on the political cost of democracy. Specifically, we include in $X_{i, t}$ the weighted average

$$
\bar{D}_{i, t-1}=\frac{\sum_{j \neq i} \exp \left(-\delta d_{i, j}\right) D_{j, t-1}}{\sum_{j \neq i} \exp (-\delta d i, j)}
$$

where $d_{i, j}$ denotes the distance between $i$ and $j$ 's capitals.
To reduce the computational burden, instead of estimating $\delta$ - the parameter determining the size of each country's effective neighborhood—we consider five scenarios. For our "medium neighborhood" scenario, we set $\delta$ equal to the estimated value of the parameter governing the spatial decay of learning in our baseline specification. We also consider a "smaller" and "smallest" neighborhood scenarios, where we increase the value of $\delta$ two-fold

Figure A2: Observed versus Predicted Prevalence of Democracy by World Region
Notes. By world region, this figure compares the true proportion of democracies (gray) with estimates generated by our learning model for both the in-sample (solid blue) and out-of-sample (dashed blue) periods. The top panel presents results using our baseline specification with no covariates. In the lower panel, we control for lagged log-GDP per capita and incumbents' time in power.
and five-fold, respectively, and a "larger" and "largest" neighborhood scenarios, where we divide $\delta$ by two and five, respectively. Table A5 presents the results of this exercise, following the format of Table 2. We find that controlling for direct diffusion provides little increase in predictive power, which indicates that it is our proposed mechanism of learning about the economic effects of democracy-and not some alternative process of diffusion-what drives our results.

Table A5: Direct Diffusion of Democracy

|  | Smallest Neighborhood <br> Learning No Learning |  | Smaller Neighborhood Learning No Learning |  | Medium Neighborhood Learning No Learning |  | Larger Neighborhood Learning No Learning |  | Largest Neighborhood Learning No Learning |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Choices <br> (\% correct) | 96.3 | 92.1 | 96.0 | 92.4 | 96.3 | 92.3 | 95.9 | 92.6 | 96.7 | 92.7 |
| Transitions (\% correct) |  |  |  |  |  |  |  |  |  |  |
| $\pm 0$ years | 11.6 | 5.4 | 12.4 | 3.9 | 13.2 | 4.7 | 20.2 | 4.7 | 18.6 | 9.3 |
| $\pm 2$ years | 41.9 | 18.6 | 54.3 | 20.9 | 54.3 | 25.6 | 50.4 | 22.5 | 56.6 | 22.5 |
| Log-likelihood | -536.6 | -1,019.1 | -539.7 | -964.3 | -511.4 | -931.7 | -553.6 | -939.3 | -481.5 | -946.2 |
| Observations | 5,925 | 5,925 | 5,925 | 5,925 | 5,925 | 5,925 | 5,925 | 5,925 | 5,925 | 5,925 |

Notes. From left to right, respectively, models in each "neighborhood" scenario control for direct diffusion effects on the political cost of democracy using distance weights $\delta=2.5, \delta=1, \delta=0.5, \delta=0.25$, and $\delta=0.1$. For each model, we report the percentage of correctly predicted in-sample system of government choices (first row). We similarly report the percentage of correctly predicted transitions to or from democracy within a 0 -year window (second row) and a 5 -year window (third row) of the event.

Robustness to alternative measure of democracy and time frame. Next, we explore the sensitivity of our results to (i) our preferred measure of democracy and (ii) the time frame.

First, as noted in the paper, various alternative measures of democracy have been employed in the literature. To test the robustness of our results to this feature of the data, we take Acemoglu et al.'s (2019) preferred measure and reestimate our baseline model. ${ }^{7}$ Since the BMR coding is more comprehensive than this alternative measure, to keep the results as comparable as possible - in particular, to avoid having to modify the time span of the sample - we use the BMR coding to fill any gaps in Acemoglu et al.'s (2019) data.

Second, to address potential concerns about the myopia of incumbents in our model and whether an annual time frame is appropriate to study changes in systems of government, we

[^6]estimate a five-year panel version of our baseline model (and true DGP). Following Acemoglu et al. (2008), we take the observation of democracy every fifth year as our measure for the five-year panel.

Table A6 summarizes the results of these robustness exercises, following the format of Table 2. Our findings are virtually unchanged.

## Table A6: Robustness to Democracy Measure and Time Frame

|  | Alternative Democracy Measure <br> Learning |  |  | No Learning |  |
| :--- | :---: | :---: | :---: | :---: | :---: |

Notes. Models in the first and second columns are estimated using Acemoglu et al.'s (2019) preferred measure of democracy with no covariates. Models in the last two columns are estimated using a five-year panel version of our data with no covariates. For each model, we report the percentage of correctly predicted in-sample system of government choices (first row) and the percentage of correctly predicted transitions to or from democracy within a 0 -year window (second row) and a 5 -year window (third row) of the event.

Robustness to alternative measures of similarity. While geographic distance is highly correlated with various dimensions of similarity across countries, we present in Table A7 results from an alternative version of our baseline specification in which we allow the crosscountry correlation in initial beliefs to also depend on genetic distance - as measured by Spolaore and Wacziarg (2009) -and on economic distance in terms of initial levels of development. For the latter, we use a linear trend to impute values of GDP per capita in 1950 for countries without such observations. We then compute the economic distance between countries $i$ and $j$ as $\left(Y_{i 0}-Y_{j 0}\right)^{2} / \operatorname{Var}\left(Y_{0}\right)$. Our results are identical.

Table A7: Robustness to Similarity Measures

|  | Learning |
| :--- | ---: |
| Choices | 95.2 |
| (\% correct) |  |
| Transitions |  |
| $(\%$ correct $)$ |  |
| $\pm 0$ years | 9.3 |
| $\pm 2$ years | 41.1 |
| Log-likelihood | -581.4 |
| Observations | 5,925 |

Notes. Results are from a specification with no covariates for the political cost of democracy but three measures of similarity to capture cross-country correlation in initial beliefs: geographic distance, genetic distance, and economic distance. We report the percentage of correctly predicted in-sample system of government choices (first row) and the percentage of correctly predicted transitions to or from democracy within a 0 -year window (second row) and a 5 -year window (third row) of the event.

Income and leader turnover. While we conceive elites broadly as the political party or faction in power in each country rather than as individual leaders, previous work has highlighted the influence individual leader exit can have on democratic transitions. To explore this, we estimate an alternative specification of our model that uses, as in Treisman (2015), (lagged) log-GDP per capita, (lagged) leader exit, and their interaction to characterize the political cost of democracy. As shown in Table A8, and consistent with our main results, accounting for learning dwarfs the explanatory benefits from such a specification.

Heterogeneous effects of growth on elite turnover. Finally, we explore whether there is heterogeneity across countries in $\theta=\left(\theta^{D=0}, \theta^{D=1}\right)$, the effects of GDP growth on elite turnover. Specifically, we estimate a version of our model where we allow $\theta$ to vary by region of the world as in Figure A2. Table A9 reports the corresponding point estimates, and Table A10 summarizes goodness of fit. Our results provide little evidence of substantively important heterogeneity.

Table A8: Income, Leader Turnover, and Democratization

|  | Learning | No Learning |
| :--- | :---: | :---: |
| Choices | 95.8 | 90.5 |
| (\% correct) |  |  |
| Transitions |  |  |
| (\% correct) |  |  |
| $\pm 0$ years | 13.3 | 7.0 |
| $\quad \pm 2$ years | 50.0 | 21.1 |
| Log-likelihood | -557.6 | $-1,150.9$ |
| Observations | 5,882 | 5,882 |

Notes. Results are from a specification that controls for (lagged) log-GDP per capita, (lagged) leader turnover, and their interaction as in Treisman (2015). We report the percentage of correctly predicted insample system of government choices (first row) and the percentage of correctly predicted transitions to or from democracy within a 0 -year window (second row) and a 5 -year window (third row) of the event.

Table A9: Effects of Economic Growth on Elite Turnover by World Region

| Region | $\theta^{D=0}$ | $\theta^{D=1}$ |
| :---: | :---: | :---: |
| Africa | -1.6859 | 5.0174 |
| Asia-Oceania | -4.0284 | 5.7846 |
| Europe | -1.7962 | 4.6478 |
| Americas | -1.9665 | 5.6278 |

Table A10: Heterogeneous Effects of GDP Growth on Elite Turnover

|  | Learning | No Learning |
| :--- | :---: | :---: |
| Choices | 95.3 | 88.9 |
| (\% correct) |  |  |
| Transitions |  |  |
| (\% correct) |  |  |
| $\pm 0$ years | 7.0 | 0.0 |
| $\pm 2$ years | 36.4 | 0.0 |
| Log-likelihood | -614.3 | $-1,390.8$ |
| Observations | 5,925 | 5,925 |

Notes. Results are from a specification where we allow the effects of GDP growth on elite turnover to vary by world region (Africa, Asia-Oceania, Europe, Americas). We report the percentage of correctly predicted in-sample system of government choices (first row) and the percentage of correctly predicted transitions to or from democracy within a 0 -year window (second row) and a 5 -year window (third row) of the event.
